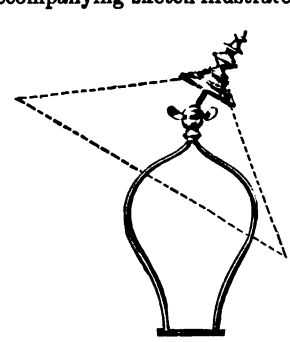
Mr. CHRISTIE, replying to the speakers, said in Londonderry the electric light had replaced 550 gas lamps by 170 arc lamps. The cost of the gas-lighting was formerly £2,200 a year. He estimated that the working of the electric light would cost about £3,500 a year, including the repayment of the loan. To that had to be added £500 which they still had to pay for the remaining nearly 200 gas lamps, making £4,000 as against £2,200. Then it must be remembered that the streets were at least 20 times better lighted than they were formerly. Again, the gas formerly cost 3s. 10d. per 1,000ft. Since the electric light had been introduced that had been reduced to 3s. 7d. As to why they had public lighting alone, he was rather of opinion the two should be run in conjunction, and that it would have been better to have worked up the two together on a small scale in a central part and extended them as it became necessary.

Mr. PERRY explained that his remarks concerning electricians and engineers were from hearsay, and he willingly accepted Mr. Lobley's personal experience in the matter that—in the particular instance mentioned—the remarks might be in error. As regarded the borough engineer becoming an expert electrical engineer, he intended to imply that the borough engineer should be sufficiently well informed to take the lead and responsibility and control, leaving the design to the expert and the carrying out the details to the electrical engineer, whom he intimated should be an official subsidiary to the borough engineer.

NEW ELECTRIC LAMP SHADE.

A very neat shade-carrier attachment for electric lamps has just been put on the market by the General Electric Company, of Queen Victoria-street. The object of this fitting is to enable silk and glass shades, used with electric table lamps, to be canted or tilted in any direction without loosening screws or nuts. The usual carrier is used, but a universal ball joint has been introduced at the top which has the shade-fixing washers attached. The accompanying sketch illustrates the shade tilted,



and should the ball become loose with wear, it can be instantly tightened by screwing up the fly-nut shown. The fitting is provided at the bottom with 1⅛in. hole to suit the B.C. holders with shade rings. As the centre of gravity of the shade and support is nearly coincident with the ball and socket joint, the shade does not tend to cant over, even when the joint is not tightened up. For reading lamps this fitting will find a ready sale.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"THE ELECTRICAL ENGINEER" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. BIGGS, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

THE TELEPHONE SERVICE.

The question put by Mr. Tully in the House on Tuesday elicited two items of interest—firstly, that the fate of British telephony is to hang undecided until next spring, and, secondly, that the Government has at present in view simply the appointment of a Select Committee to consider and report upon the evidence taken by Mr. Arnold Morley's Committee. We trust that more liberal counsels will, however, prevail when the time for deciding the scope of the new committee arrives. Our opinions on the telephone problem are well known. We believe that, given a monopoly, that monopoly should be a national one; for there is no eluding the fact that the present system has broken down in practice, and has procured for our country the reproach of being not only not foremost in telephony, but well-nigh last. This reproach is peculiarly hard to bear by the pioneers in the kindred art of telegraphy and by the countrymen of Bell and Hughes, who, without prejudicing the claims, as inventors or discoverers, of Bourseul and Reis, may justly be hailed as the most potent workers in the domain of practical telephony, for the one gave us the first practical receiver and the other the first really efficient transmitter.

But while advocating the transfer of the telephones to the State as being probably, on the whole, the best solution of an acknowledged difficulty, we deprecate any undue hurry or any disposition to move in that direction except on good, substantial, and well-ascertained grounds. The Post Office made a great mistake in 1870 when it paid too much for its telegraphs; it erred again in 1879 when it declined to welcome the newly-born telephone as an adjunct and supplement of the telegraph; and it was not too well advised when, subsequently and after its blunder had become manifest, it punished the public by putting obstacles in the paths of its own licensees, and so restraining the efforts which were certainly made to force the extension of the new convenience. Such frequent deviations from the path of what time has shown to have been the true policy tend to beget caution in even the most sincere friends and well-wishers of the permanent officials, and to accentuate the natural desire of business men that thorough investigation should precede action, in order that the edifice of error may not receive a final pinnacle. For this reason we think that public policy would not be served by limiting the next committee to the consideration of the evidence already taken. It must not be overlooked that the fairness of the late committee has been questioned in more than one quarter. Some of its members have been challenged as shareholders of the monopolist company; its chairman's zeal for Post Office acquisition is alleged to have somewhat blinded him to the true function of the committee, and to have betrayed him into an advocacy of the existing system which is not warranted by the state of public opinion. Certainly, witnesses were examined who had no pretensions to be considered telephonic experts, while the testimony of other gentlemen whose right to be heard cannot

Digitized by Google

be gainsaid was rejected by—as the recently-published minutes of evidence show—the casting vote of the chairman. When the question comes up for final settlement, as it must do early in the ensuing year, we trust that there will be no desire to continue this line of conduct. The matter has to be reopened: let it be properly sifted. If the Post Office has a good case to present, as we believe it has, it should welcome, and not fear, the most drastic investigation possible.

The troubled sea of politics through which the bark of State has recently steered has dealt hardly with the late Telephone Committee, for submerged and beyond our ken as public men lie not only its chairman (Mr. Arnold Morley), but Sir Charles Cameron, whose thorough grasp of the subject was recognised by all; Mr. Fletcher Moulton, Mr. J. W. Benn, and Mr. Snape. The committee must, therefore, to a large extent be reconstituted, and advantage of the fact should be taken to exclude shareholders in the National Telephone Company and all others whose present interests or past connections render their perfect impartiality a matter of doubt.

CITY AND GUILDS EXAMINATION.

We have received a report from the gentleman who adjudicated on the papers sent in to us in answer to the questions set for the 1895 examination. He states that the students uniformly avoided the honours grade, evidently preferring to exhibit their knowledge by choosing the easier questions set in the ordinary and the preliminary grades. There has been some difficulty in judging fairly between the competitors, owing to a want of conciseness on our part when offering the prizes. Some have considered that our offer of books for the best set of answers to the paper meant that all the questions must be answered, in order that a complete set could be published. This was not our idea, as we wished the regulations printed at the head of the paper to be followed in every respect except as to time. The result has been specially felt in correcting the answers to the ordinary grade, where a number of really good sets of answers have been returned to us. We have, therefore, decided to give two prizes in this grade—one to the competitor who has answered the best set of eight questions, and one to the gentleman sending in the best complete set. The great fault running through nearly all the sets sent in has been, we are informed, in the sketches. These show that the students have not sufficiently exercised themselves in sketching the apparatus they see and use. This art, which cannot be too highly valued, can be acquired by most people if only care and time is given in the first few years of their professional career, and in after-life few acquirements will be found more useful in daily practice. The other error in detail is the average answers sent in by the competitors, and will be dealt with by our examiner.

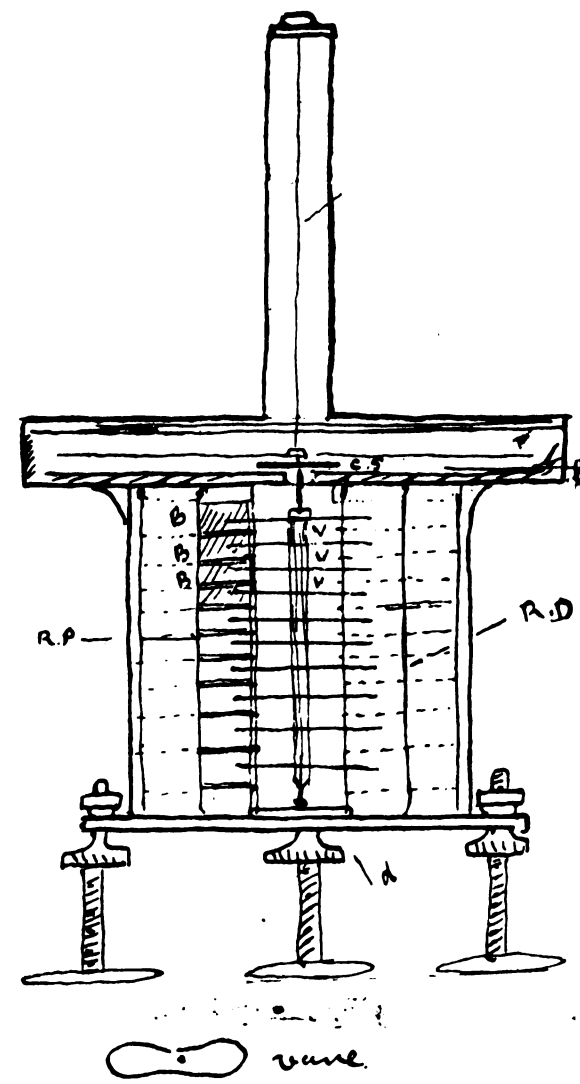
The two successful competitors in the ordinary grade are Mr. W. Shepherd, of Brockley, and Mr. E. B. Wedmore, of Bristol. We shall have pleasure in forwarding to each of these gentlemen any books they may select to the value of two guineas. The result in the preliminary stage will be published shortly.

The following is the set of answers sent in by Mr. W. Shepherd, of 41, Manor-road, Brockley. The examiner's notes or corrections to this individual paper have been curtailed as much as possible, and the errors common to several competitors will be discussed more fully in our next week's issue, when Mr. Wedmore's paper will be published.

ELECTRIC LIGHTING AND POWER DISTRIBUTION.

Ordinary Grade.

1. Describe and give a full-size hand-sketch of one of the modern kinds of electrostatic voltmeters.



Answer.—The figure shows a horizontal pattern of multicellular electrostatic voltmeter. A set of 10 aluminium vanes, V, are suspended by a fine wire suspension and separated by distance-pieces. The vanes are hung so as to rest in their normal position just outside a set of triangular brass quadrant boxes, B. A fine coach spring, C S, is placed between the vane spindle and the suspension wire; this saves the suspension from injury if the instrument is roughly set down. Two vertical brass repelling plates, R P, are fixed to the base; these also act as guards to prevent the vanes moving beyond the correct limits. The whole instrument is enclosed in a brass case, and mounted with levelling screws. A long aluminium pointer moving over a horizontal scale gives the volt readings which are correct for alternate current. A torsion head at the top of the case controls the zero. The sketch is one-third full size.

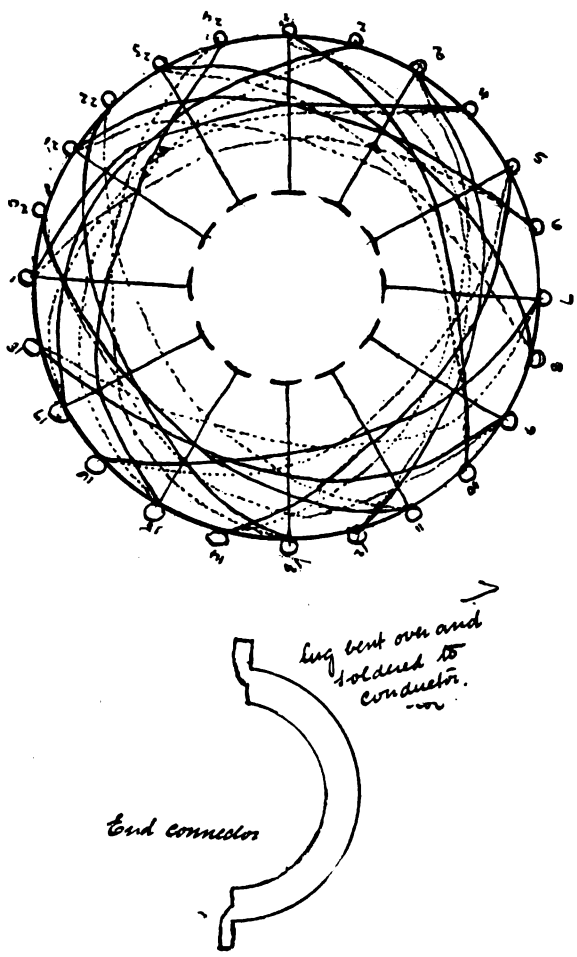
Note.—The principle of action should be described, and the reason of the multicellular construction explained.

2. What is the use of the series coil in arc lamps run in series with an unvarying current?

Digitized by Google

Answer.—The object of the series coil in constant-current arc lamps is to separate the carbons and strike the arc, maintaining it so long as the P.D. between the carbons is the correct amount. Should this increase owing to the arc becoming too long the shunt coil gets the mastery, and the carbons feed together.

3. Sketch a drum armature showing the connections and windings for 24 conductors on the outside. Sketch also any methods of end connection for drum machines in ordinary use.



Connect across $\frac{1}{2}$ (24) − 1 bars.
The dotted lines are the back connectors.

4. What are the advantages and disadvantages of running incandescent lamps at high efficiency?

Answer.—The advantages of working lamps at high efficiency are: (1) the first cost of installation will be less, as fewer lamps are needed; (2) a considerably increased light for a very small extra expenditure of power. The disadvantage is that the life of the lamp is very much shortened, and the cost for renewals becomes greater. As to which would be the most economical method of working, depends on cost of power, lamps, etc., at that particular locality.

5. Draw a solenoid showing roughly the lines of force before and after the introduction of a soft iron core.

Note.—Mr. Shepherd's sketch was much too rough for reproduction, and density, rather than direction, was shown by it.

6. How does slipping a copper tube over the core lessen the spark of an induction coil?

Answer.—Powerful eddy currents are set up round the copper tube, which directly opposes the primary field, thus weakening the effective induction through the secondary coil and diminishing the potential and spark.

Note.—It is the rate of change of induction which is most affected by the eddy currents. The E.M.F., being a function of the rate of change, is kept low, and hence the sparking is reduced.

7. How would you wind a medium-sized motor (say 10 h.p.) to run at constant speed with varying load? And how would you start such a motor?

Answer.—A shunt winding with a few series turns connected so as to demagnetise the field. To start the motor, switch the shunt across the mains, then the armature with the series turns reversed so as to assist the shunt. When speed has got up, the series coil is switched back in opposition.

Note.—More reasons for the statement should be given. Resistance should be used when starting.

8. What are foot-pound, poundal, dyne, and kilogram-metre? And how are they related?

Answer.—Foot-pound—The work done when a resistance of 1lb. weight is overcome through 1ft.; poundal—the force which acting for one second on 1lb. mass gives it a velocity of 1ft. per second; dyne—that force which acting on one gramme mass for one second gives it a velocity of 1cm. per second; kilogram-metre—the work done in overcoming one kilogramme weight through a distance of one metre.

One foot-pound = 13,825 centimetre-grammes;
$= 13{,}825 \times g = 1{\cdot}356 \times 10^7$ ergs (approx.),
where g is the acceleration of gravity in centimetres per second.

One poundal gives 1lb. an acceleration of 1ft. per second, or 453·6 grammes . . . . 30·48cm. per second. As a dyne gives one gramme 1cm. per second acceleration, ∴ a poundal = 453·6 × 30·48 = 13,825·73 dynes.

$$1 \text{ dyne} = \frac{1 \text{ erg}}{1 \text{ centimetre}};$$

1 kilogram-metre = 100,000 gramme-centimetres.
$= 100{,}000 \times g$;
or, $100{,}000 \times 981$;
$= 9{\cdot}81 \times 10^7$ ergs.

Note.—The methods and results are not clear.

9. If 10,000 kilocoulombs are passed through cells arranged in series containing solutions of Cu_2Cl_2, $Hg_2(NO_3)_2$, $CuSO_4$, H_2SO_4, and NaCl, how much copper, mercury, hydrogen, and caustic can be obtained?

Answer.—Weight in grammes = coulombs × electro-chemical equivalent.

Cu_2Cl_2 (cuprous chloride) 10,000,000 × ·00065419 = 6,541·9 grammes copper.

$Hg_2(NO_3)_2$ (mercurous nitrate) = $10^7 \times {\cdot}0020747 = 20{,}747$ grammes mercury.

$CuSO_4 = 10^7 \times {\cdot}00032709 = 3{,}270{\cdot}9$ grammes of copper.

H_2SO_4 (pure undiluted sulphuric acid) will not electrolyse. If mixed with water, then $10^7 \times {\cdot}0000\,10384 = 103{\cdot}84$ grammes of hydrogen are liberated.

NaCl $10^7 \times {\cdot}000\,23873 = 2{,}387{\cdot}3$ grammes of sodium.

In 40 parts NaOH there are 23 parts sodium;
∴ 23 : 2,387·3 : : 40 : x grammes caustic;
∴ x = 4,151·8 grammes caustic soda.

10. What are the advantages and disadvantages of the Planté and pasted plates for secondary cells?

Answer.—The principal advantage of the Planté cells is that they can stand rougher treatment, and take higher rates of charge and discharge without damaging the plates, than the Faure type. Their disadvantage is the longer and more troublesome formation needed to produce a good depth of active material on the plates. The advantages of the pasted plates are: (1) the short time and small expenditure of energy necessary for the formation of the plates; (2) the greater capacity for a given bulk of cell. On the other hand, the paste is apt to fall away from the plate, especially if the normal current is much exceeded; this may lead to short circuiting, besides loss of capacity.

11. What are the advantages of separate field magnets for the two armatures in continuous-current transformers?

No answer was given by the competitors.

12. A series dynamo has an armature resistance of 0·4 ohm and a field resistance of 0·6, and gives 120 terminal volts at a given speed and current of 10 amperes: work out its electrical efficiency as a dynamo and as motor at that speed and current.

Answer.—The total internal resistance of the machine is

Digitized by Google

·4 + ·6 = 1 ohm. The volts lost internally = 1 × 10 amperes = 10.

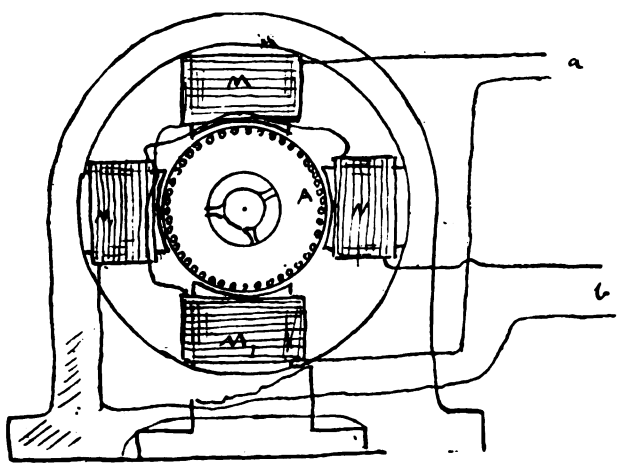
$$\therefore \eta = \frac{10 \times 120}{10 \times 130} = \frac{1,200}{1,300} = 92{\cdot}3 \text{ per cent.}$$

As a motor at same speed, the back E.M.F. will be 120 volts, and the terminal volts 120 + 10 = 130.

$$\therefore \eta = \frac{120 \times 10}{130 \times 10} = 92{\cdot}3 \text{ per cent., as before.}$$

Note.—The last part is wrong; the back E.M F. in the machine, at the same speed and field excitation, will be 130 volts—hence the terminal voltage will be 140, and the efficiency 92·8 per cent.

13. Describe one kind of alternate-current motor.



Answer.—The above is a rough sketch of a Ferraris rotary field motor. Two pairs of laminated magnets, M M_1 and N N_1, are excited from two separate alternating circuits differing by 90deg. in phase. The resultant action of these two oscillating cross fields is to produce one rotating field of almost constant value. The armature, A, is simply a drum with the conductors connected in parallel by massive copper end pieces. In order to reduce the air-gap, the conductors are passed through holes in the periphery of the core discs. Currents are induced in the closed armature by the revolving field, and a torque is thus produced which varies as the difference in speed between the armature and field.

14. When are alternate-current systems better than continuous-current systems? Give your reasons as fully as possible.

Answer.—When the distance between the station and points of distribution exceed about 1,000 yards it is more economical to use alternating currents, as high voltage can easily be used and the feeder mains kept a small sectional. The high voltage can be transformed down with facility for distribution. When the district is straggling, alternating currents of high tension would be the best, as transformers may be used to reduce the volts as required, and these need no attention. For transmission of power over long distances, or in any case where a very high potential is required, this can be best produced by alternators, as they can be more easily and safely constructed to bear the strain than continuous-current machines. Lastly, in cases where skilled labour is scarce, alternating plant may be better, as regulation and management is simpler, there being no large commutators to look after.

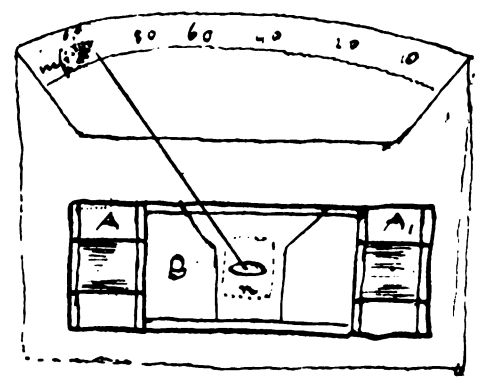
15. What peculiarities are there in the design of a dynamo for supplying arc lamps in series at (say) 3,000 volts?

Answer.—Dynamos for supplying arc lamps in series are usually of the open-coil type with ring armatures. Great care is necessary in insulating the armature coils from each other and from the core, and in some cases the whole machine is insulated from the ground. In the commutator there are many peculiarities, the principle being the fewness of the segments and the heavy insulation between them. The armature coils are consequently few in number and their self-induction considerable, but this is an advantage. Multipolar fields are frequently used, the magnets being worked at a high induction. They are series wound, and there is some mechanical or electrical device for automatically keeping the current constant, either by shifting the brushes or by varying the field excitation.

17. What is your idea of the advisability of earthing the secondary in transformer systems?

Answer.—Although all danger of a shock from the high voltage may be avoided by well earthing the secondary coil, it is not advisable to do so, as there would be a constant strain on the insulation of the system, and should a fault actually occur the leakage might be serious, with, perhaps, a total failure of current. A safety device, which only earths the house circuit, if the potential between it and the earth assumes a dangerous value, is preferable.

18. What is the construction of an ohmmeter?



Answer.—In the ordinary form of ohmmeter represented in section above, there are three coils—two, A A_1, being wound in a vertical plane parallel to each other, while the third one, B, is wound in a plane at right angles to the first. At the common centre of the three coils is a small steel needle moving horizontally, the coil B being cut away to give the pointer a wide range. The coils A A_1, which are of high resistance, are coupled in series, and connected to some source of fairly high E.M.F., while B is placed in series with the resistance to be measured and the same E.M.F. Any current through B will give a deflection to the needle, which is read off the scale in megohms. Under the instrument is a small magnet to counteract the magnetic force of the earth.

19. Why does an electromagnet spark on breaking the exciting circuit?

Answer.—When the circuit is broken the lines of force round the magnet suddenly collapse, cutting the exciting coil, and inducing an extra current of high potential in the same direction as the exciting current. This tends to keep up the current, although the circuit is broken, and a spark results.

20. How are the pull and self-induction of an electromagnet connected?

Answer.—The self-induction of an electromagnet for unit current = L = $\frac{4\pi\mu a t^2}{l}$ absolute units. a = area of coil in centimetres; t = turns; l = length. The pull is expressed by $P = \frac{B^2 \times a}{\delta\pi}$ dynes.

Now $B = \frac{4\pi t \mu}{l}$ for unit current;

$$\therefore L = B a t;$$

$$\therefore \frac{P}{L} = \frac{\frac{B^2 a}{\delta\pi}}{Bat}$$

or, $$P = \frac{L B}{\delta\pi t},$$

which expresses the relationship.

21. A condenser having a capacity of two microfarads is connected to two terminals maintained at 2,000 volts; how

Digitized by Google

much work is taken from the terminals, and how much can be got out of the condenser again?

Answer.—Work taken up $= \frac{K V^2}{2}$ joules, where K is in farads and V in volts. Or in this case

$$\frac{2 \times 10^{-6} \times 2{,}000^2}{2}$$

$$= \frac{2 \times 10^{-6} \times 2 \times 10^6}{2} = 2 \text{ joules},$$

or, $$\frac{4}{2{\cdot}712} = 1{\cdot}475 \text{ foot-pounds.}$$

The condenser will give back this amount of work again, if there is no leakage.

22. What magnetic quantities are denoted by the symbols H, B, and μ; and how are they related to one another?

Answer.—H denotes the intensity of a magnetic field surrounding a magnet. It is measured at any point by the mechanical force which a unit pole experiences if introduced into the field at that point. B is the magnetic induction or number of lines of force per unit area passing through a material placed in a magnetic field. μ, the permeability of a substance, or its relative conductivity for lines of force compared to air.

$$B = \mu H;$$

$$\mu = \frac{B}{H};$$

$$H = \frac{B}{\mu}.$$

23. Given a ring armature 10in. long, 10in. diameter, 1in. radial thickness of iron, what wire would you use to give 110 volts, and what current would be suitable? Speed, 1,000 revolutions per minute.

Answer.—

Ring armature, 10in. long;
10in. diameter, 1in. depth of core;
110 volts;
1,000 revolutions a minute.

Assuming as a fair induction 14,000 lines per square centimetre. The cross-section of armature core $= 10 \times 2 = 20$ square inches $= 129$ square centimetres.

Then $$110 = \frac{C \times 129 \times 14{,}000 \times 1{,}000}{60 \times 10^8},$$

or, $$C = \frac{110{,}000}{301} = 362 \text{ as nearly as possible.}$$

$\therefore$ number of external conductors needed $= 362$.

The circumference of core $= 10 \times \pi = 31{\cdot}4$in.

$$\frac{31{\cdot}4}{362} = {\cdot}0867\text{in.} = \text{diameter of insulated wire.}$$

Allowing 15 mils for insulation, this leaves ·0717in. as the diameter of copper wire = about No. 15 S.W.G. This would allow eight amperes at 1,000 per square inch, or 16 amperes as output of armature.

If wound in two layers

$$\frac{31{\cdot}416}{181} = {\cdot}1735\text{in. diameter of wire.}$$

Giving 20 mils for insulation, this leaves 153·5 mils for the diameter of wire. This, at 1,000 amperes per square inch $= 18\frac{1}{2}$ amperes, or 37 as the total current.

Note.—A higher induction in the iron core could be used, but allowance must be made for the paper insulation in working out the section of the core. Not more than 90 per cent. of the gross area of the laminated core will be iron. Again, a much higher density of current in the copper conductor can be used, and this competitor should work rather to watts wasted per square inch cooling surface than to density.

SOME USES OF CURVES IN ELECTRICAL PRACTICE.

BY H. H. SIMMONS, A.I.E.E.

(Continued from page 148.)

In Fig. 10 are given some well-known curves, such as the circle, the ellipse, and the parabola. The equations to these curves, or, as they are often called, the laws of these curves, as drawn, are written on them, and the constants used are given below:

Circle: $x^2 + y^2 = a^2$. $a = 4$.

Ellipse: $\frac{x^2}{a^2} + \frac{y^2}{b^2} = c$. $a = 9$, $b = 4$, $c = 1$.

Parabola: $y = K\sqrt{x}$. $K = \sqrt{10}$.

These laws are for the curves in the positions drawn in Fig. 10; if the origin were changed we should have to

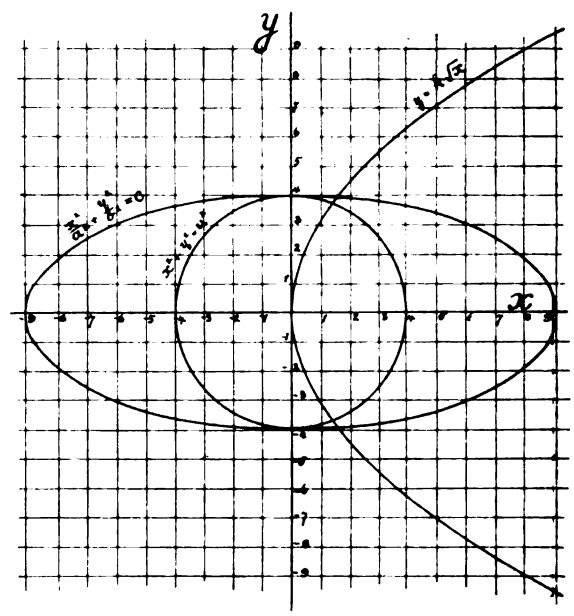


FIG. 10.

make a corresponding change in the law—for instance, if the centre of the circle were not in O, its law would be $x^2 + y^2 - 2ax - 2by + a^2 + b^2 = r^2$, where a and b are the X and Y ordinates respectively of the centre, and r = the length of the radius.

In Fig. 11 are shown two hyperbolas. The one whose law is $xy = a$ being of interest in practice, in that it is the curve which results when, on a dynamo characteristic, we join points of equal horse-power: x may represent amperes and y volts, while a is the number of watts, the product of the two.

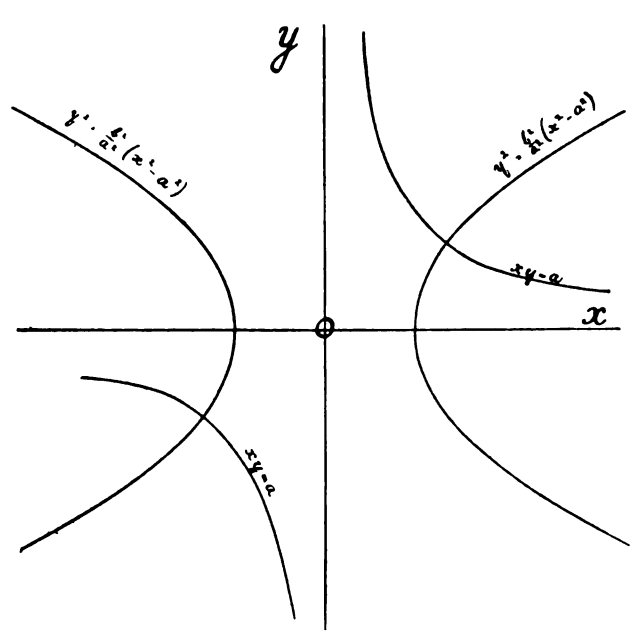

FIG. 11.

We have now had before us the basis and procedure of all curve plotting by rectangular co-ordinates, and have arrived at the point in theory beyond which it is impossible to proceed without at least some knowledge of elementary mathematics. We are not debarred from gleaning considerable information, however, from the curves in common use in practice.

Perhaps to the man who has never troubled his head

Digitized by Google

about more than he could help, the curve showing the output of a dynamo at constant speed is the most familiar. It is presumably unnecessary to remark that, although an approximately constant speed is common enough for dynamo driving, an absolutely constant speed is the reverse of common. In Fig. 12 is given the characteristic—*i.e.*, output curve—of a series machine. This is obtained when the speed is kept as constant as possible, and the resistance of the magnet coils and armature windings are as nearly so as may be, the whole temperature of the machine being assumed constant.

In this figure we have three distinct curves drawn, to which are attached the letters E, V, and I respectively. The curve V is that connecting the voltage at the terminals of the machine and the current in the external circuit, that marked E connecting the internal E.M.F. with the external current, and I having special reference to the internal resistance of the machine, as will be seen further on.

The curve V is obtained, as must be well known, by taking simultaneous measurements of the pressure at the terminals of the machine and the current going to the external circuit. Pressure, or voltage, is then (by unanimous consent to follow Dr. Hopkinson, who in 1879 originated the practice) plotted to a vertical scale, while current is plotted horizontally. This places before us a concise representation of the capabilities of the machine, far easier to follow than any two rows of figures, and far more handy to deal with, as we shall see. Let us endeavour to find what the internal E.M.F. of the machine is at any

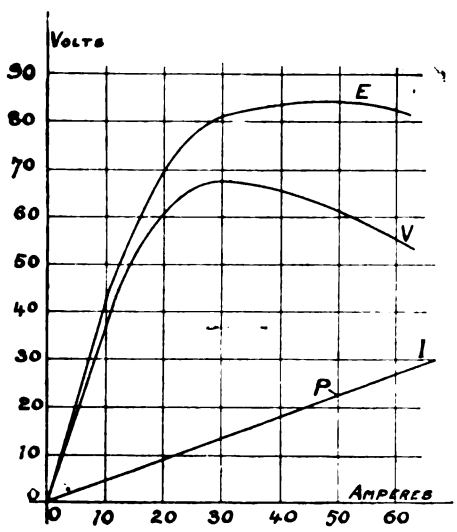

Fig. 12.

output. We know that it is the terminal E.M.F. plus the volts lost in the internal resistance of the machine. If this internal resistance be 0·45 ohm, then to get the volts wasted in this resistance we have to multiply this at every point by the current flowing. This is easily done on the curve by drawing a suitable straight line. From our previous article we know that $mx=y$ is a straight line through O, the origin, and so, to multiply x or y by a figure m, we have only to draw such a line—as for instance, O I, in which 0·45 × current = volts; thus at 50 amperes we have a point 22·5 volts. It is easy to see that the greater the internal resistance the greater the slope of this line, O I—*e.g.*, if it were 0·5 the point, P, would be (at 50 amperes) 25 volts, and if the internal resistance were 0·6 ohm the point at 50 amperes would be 30 volts.

The slope of this line is evidently then a figure representing the internal resistance of the machine. If our scales for volts and amperes are equal, as is rarely convenient, the tangent of the angle I O X gives this figure; if the scales are unequal, we must of course read the values on those scales and divide volts by amperes to get resistance. We now have merely to add to the height of the curve V at every point the height of the points on I at the same currents, in order to obtain the internal E.M.F. of the machine. This has been done on the diagram, and the Y ordinate (or volts) of any point on the curve E is equal to the sum of the Y ordinates (or volts) of the points on V and I at that same current.

TESTS OF A POLYPHASE MOTOR.

BY D. C. JACKSON.

We hear much in these days in regard to the advantages of two-phase and three-phase alternating currents for the transmission of power, but comparatively little information is obtainable in regard to the actual performance of the motors, as shown by impartial tests that may be relied upon. The records of independent tests made in Switzerland, Germany, and France are to be found in various foreign periodicals and in the journals of foreign engineering societies, but very few such records are found in English printed journals. Dr. Louis Bell has given us much information based upon his experience in regard to the performance which may be expected of polyphase induction motors, and Mr. Steinmetz has, from time to time, added much to the general fund of knowledge bearing on their design and performance. Complete tests of American polyphase motors are not presented to us by these gentlemen, though Dr. Bell has given some interesting comparisons between alternating and continuous current motors. The comparative curves which he gives seem to be almost the only ones which have been presented in America. On this account the results of tests made upon a three-phase motor at the University of Wisconsin are of interest.

Particular interest attaches to polyphase motors at this moment because the manufacturers of polyphase machinery are pushing beyond the boundary of long-distance transmission of power into the field of the distribution of power in factories—inter-machine distribution, as it may be called. In the latter work the polyphase motor enters into direct competition with the continuous-current motor, and the

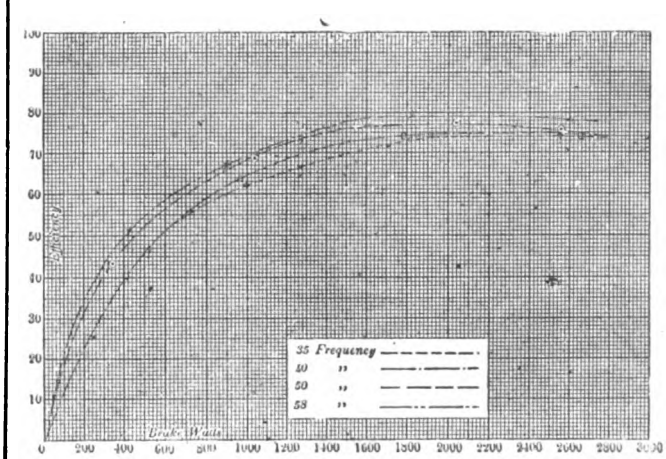

Fig. 1.

performance of machines of small size must be particularly excellent if they can take an equal place with continuous-current motors. For long-distance transmission of power the alternating current presents such remarkable transmission advantages that defects may be overlooked in the motors which would condemn them for use in inter-machine distribution, where economy and close regulation on the part of small motors are factors of the greatest importance.

The motor for which tests are here given belongs to the dynamo laboratory of the University of Wisconsin, and is used for testing in the regular course of laboratory instruction. It was made by the Allgemeine Elektricitats Gesellschaft, of Berlin, Germany, in 1893. Its rated power is from 3 h.p. to 5 h.p. at a speed of 1,500 revolutions per minute, which is the theoretical speed which it should attain at a frequency of 50 (6,000 alternations per minute). The fields of the motor are "mesh" wound for a pressure of 100 volts between the leads, and the armature is of the common "squirrel-cage" type—that is, the armature conductors consist of straight rods threaded through holes close to the periphery of the armature core, all the conductors being connected together at each end by copper short-circuiting rings. Tests of the motor have been made with a wide range of frequencies, the triphase current being furnished by means of a rotary transformer which furnishes a convenient means of getting three-phase currents of any

Digitized by Google

desired frequency between 35 and 60. The alternating current developed by this rotary transformer is probably quite close to sinusoidal. The transformer is limited in its current-carrying capacity, and the motor has therefore not been tested beyond about 3·6 b.h.p. In testing,

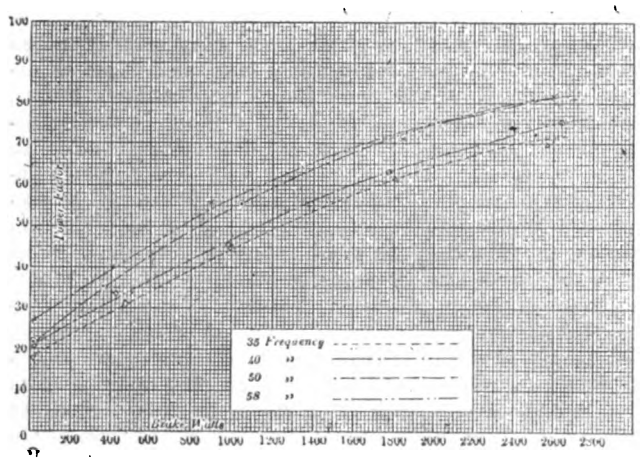

FIG. 2.

the output of the motor has been measured by means of a Prony brake, the input by means of a Weston or an electro-dynamometer wattmeter, the current in each circuit by means of an electro-dynamometer, the pressure between the three terminals and the centre

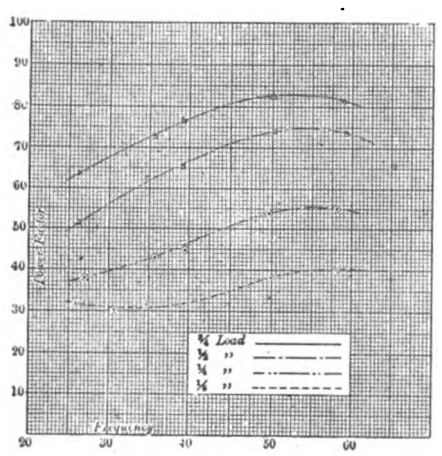

FIG. 3.

of the mesh by a Weston alternating-current voltmeter, all being carefully standardised.

The results are given graphically in Figs. 1, 2, and 3. Fig. 1 shows efficiency curves for the motor when driven at frequencies of 35, 40, 50, and 58. The revolutions per

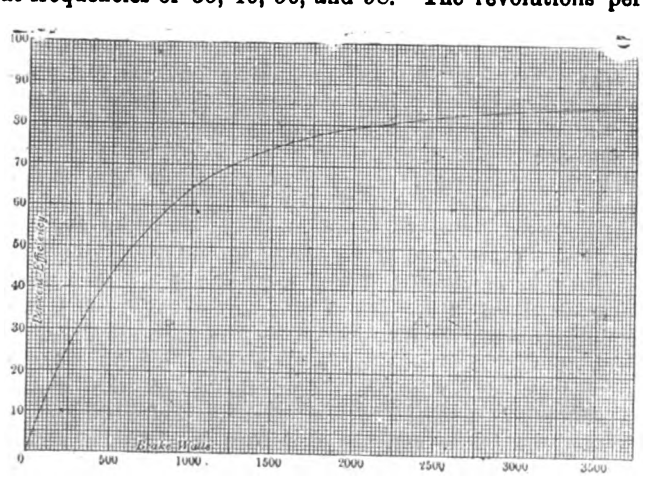

FIG. 4.

minute made by the armature of this motor are theoretically 30 times the frequency, or one-fourth the number of alternations per minute. Consequently, the theoretical test speeds corresponding to the curves in the figure are 1,050, 1,200, 1,500, and 1,740 revolutions per minute. The efficiency of the motor over the whole range of frequencies is very good, and in comparison with Fig. 4 it may be said upon the whole to compare favourably with the corresponding efficiences of a continuous-current motor. Fig. 4 is an efficiency curve taken from a 5-h.p. continuous-current motor of a well-known manufacturer. The drop in speed of the alternating-current motor between no load and full load is about 7½ per cent. at the best frequency, while the regulation of the continuous-current machine is almost perfect.

Fig. 2 shows the variation with load of the power factor (ratio of wattmeter reading to product of ampere and volts) at the four frequencies, and Fig. 3 shows the relation of power factor to frequency at different loads, counting full load as 5 b.h.p. It will be seen from these curves that the highest power factor does not much exceed 80 per cent., and that this motor must always demand upward of 20 per cent. more current from the generator which supplies it than is actually represented by the motor's output.

Results of tests of a similar motor are reported in *L'Industrie Electrique* for May 10, 1893, and agree quite fully with the results just given. The general results are condensed into the attached table:

TESTS—*L'Industrie Electrique.*

Motor.	Type.	H.P.	Max. h.p. at test.	Max. eff. Per cent.	Drop in speed at full load. Per cent.
A.E.G. three-phase...	DR 50	5	5	84	6½
	Wisconsin University.				
A.E.G. three-phase...	DR 50	5	3 6	80	7½
Continuous current...	—	5	5	85	0

It is unfortunate that the test on the alternating-current motor could not be made upon an American machine of one of the types now coming into use, but there has been none available for the work. The American machines have the same general constructive characteristics as the motor tested, and are likely to differ but little in their performance. The curves show a greater advantage to the credit of the continuous-current motor than is given it by Dr. Bell.

METALLIC LACTATES FOR ELECTRO-PLATING.

In connection with a paper on the electrolytic deposition, for analytical purposes, of metals dissolved as lactates or glycolates, Dr. Jordis, of Munich, pointed out that lactic acid provides an excellent solvent for electro-plating. As yet experiments have only been made in the laboratory with plates of 30 square inches surface. The deposits form so uniformly and easily, however, and adhere go well, that there is great hope for technical processes based upon Dr. Jordis's researches. The expensive free lactic acid is not required. In Germany lactic acid is quoted at 590 marks—as many shillings—per 100 kilogrammes (220lb.); a fairly pure acid can be obtained for 300 marks, while pure lactates of calcium and zinc, from which the acid is generally separated, cost 190 and 435 marks. Coatings of copper and brass of varying shades on iron, zinc, or copper, of zinc on iron and copper, and of iron and of nickel can be obtained without difficulty, without any special apparatus. Whether the latter point will be confirmed in operations on a larger scale remains, of course, to be seen. As to zinc, Dr. Jordis does not appear to have been particularly successful. In any case the process has great interest for engravers, whose blocks are not as a rule of large dimensions, and particularly for the silver-plating industry. Amalgamated brass is, in a bath of lactate of silver, covered with a pure white coating of silver, which takes the highest polish. It would be a great boon if we could replace the dangerous cyanide of potassium by the harmless lactic acid. The connection with milk might suggest bacteria, as the decomposition of the lactic acid into carbonic acid and acetal aldehyde need not, in the vat, proceed as certainly as it does in platinum dishes. But lactic acid is itself regarded as antiseptic, and the electric current, though perhaps not so fatal to micro-organisms as is often asserted, does not favour their development. The communication was brought before the recent second annual meeting of the Deutsche Elektrochemische Gesellschaft at Frankfort-on-Main,

LIGHT RAILWAYS AND TRAMWAYS.*

BY R. H. DORMAN, M.I.C.E., COUNTY SURVEYOR, ARMAGH.

So much has been written regarding light railways and tramways during the past few years that it is difficult to prepare a paper containing any new matter on these subjects. It is probable, however, that nearly all the members of this association are called on occasionally to report in some way or another respecting their construction, and it is therefore to be hoped that the few remarks which the author proposes offering may give rise to an interesting discussion.

The author has thought it advisable to confine his remarks chiefly to light railways and tramways as constructed in this country. Although he was engaged for some time on railway work in England, and superintended the construction of the Highgate-hill Cable Tramway for the Hornsey Local Board, he is better acquainted, and has been connected for the greater part of his life, with work of this kind in Ireland. It is not proposed to deal with the lighter descriptions of tramways—namely, such as might be laid down in order to connect a series of farms with a neighbouring town. Such tramways are not required at present, and probably never will be required in this country.

A light railway in Ireland is defined by the 31 and 32 Vict., c. 119, as a railway on which the weight of one pair of wheels of the engine does not exceed eight tons, and the speed adopted does not exceed 25 miles per hour. The chief difference between a light railway and a tramway appears to be that a light railway is run over land which is specially acquired for the purpose, while a tramway runs over or alongside a public road, and the speed is limited to 12 miles an hour in the country and to six miles in towns and villages.

Light railways and tramways in this country may be classed as follows:

1. Light railways both of the ordinary 5ft. 3in. gauge and narrow gauge. The line known as the Bessbrook and Newry Electric Tramway should be properly classed as a light railway, as it runs over specially acquired land all the way, except where it crosses the public roads.

2. A composite type. Those which run for part of their course over specially acquired land, and for part of their course along the public road.

3. The Lartigue system.

4. Tramways of various gauges and worked by steam, by electric power, by a combination of steam and electricity, and by horses.

The light railways and tramways in Ireland have been constructed:

1. As feeders to existing main lines.

2. To open up tracks of country through which no railways run, and in which there is no probability of heavy trunk lines ever being constructed.

3. Horse tramways in the larger towns.

4. Short lines for the accommodation of special industries.

The capital for the construction of the fourth class has usually been obtained from private sources, and for the third class it has been obtained in the open market. Previous to the Act of 1883 the capital for the first and second class was obtained by the barony, or baronies, through which the line passed, giving a guarantee for a portion of the capital, generally for a limited number of years, afterwards ratified by a special Act of Parliament, which also authorised a loan from the Board of Works and the issue of ordinary shares. In 1883 a special Act of Parliament was passed by which the Treasury guaranteed to the county a maximum of 2 per cent. when the grand jury gave a guarantee of 4 per cent. or more; this Act also conferred powers for the compulsory purchase of land, and did away with the necessity of obtaining a special Act for each particular line. A considerable stimulus to the construction of light railways and tramways was given by this Act, but it is to be regretted that the 2 per cent. guarantee given by the Treasury was not made a direct guarantee. If a direct guarantee of 3 per cent. were given by the Treasury, a portion of which would of course be raised by the county, it would be as easy or easier to find the necessary capital for the construction of a line than it is now with a guarantee of 4 or 5 per cent. from a grand jury.

As a general rule the light railways of the ordinary gauge are worked, and the rolling-stock or part of it provided, by the railway company to which the light railway forms a branch, or of which it is an extension, for a percentage usually 50 to 55 per cent. of the gross receipts. A working agreement of this kind is always favoured, and sometimes insisted on, by the Treasury as some security that a line will be kept open. Instances of railways having been opened for traffic and afterwards abandoned have occurred; as, for example, the Parsonstown and Portumna Railway, the rails, sleepers, and even the station building of the railway having been appropriated and removed by the country people. It may be mentioned here that the majority of these railways have at first proved anything but remunerative, and in some cases the receipts have proved insufficient to meet the working expenses; but almost invariably the receipts are found to increase annually, and in some cases these railways are now able to pay not only the baronial charges, but also a dividend on the ordinary shares, or a contribution to the baronies, as specified in Section 5, c. 43, 46, and 47 Vict. This result proves that increased traffic is created by the construction of these railways in the districts through which they run, and the ultimate benefit to these districts can hardly be over-estimated.

Gauge of Light Railways and Tramways.

The great majority of engineers in this country favour the adoption of the Irish 5ft. 3in. gauge, and with good reason. Railways in this country can generally be constructed easily and cheaply; they are to a great extent surface lines, and as a rule no expensive works are required in connection with them. By the adoption of the narrow gauge there would doubtless be a slight saving in the cost of land, in masonry works, in earthworks, and in ballast, but there would be no saving in the promotion of the scheme in the first instance, nor in station buildings, nor in fencing, nor in signalling, etc., and not much saving in maintenance and working expenses, while the advantages of being able to interchange rolling-stock with other lines far outweigh the slight saving in cost effected by adopting the narrow gauge. Moreover, the rolling-stock adopted for narrow-gauge railways is not suitable for the conveyance of cattle, one of the most important items of traffic over Irish lines.

In the case of tramways the gauge which should be adopted is more difficult to decide. For tramways running along the side of a public road, in which case the rails need not be kept on a level with the surface of the road, a 3ft. gauge will probably be found the most suitable; a greater width of roadway (which must not be less than 18ft.) can thus be left than if a wider gauge were adopted, and sharp bends in the road can be manipulated more easily. In the case of tramways running over a central track, the 4ft. 8½in. or 5ft. 3in. gauge is usually considered the most convenient.

Curves and Gradients.

For light railways of the ordinary gauge the sharpest curve usually adopted is 10 chains, but I have occasionally known curves as sharp as seven chains put in. For light railways of the 3ft. gauge curves as sharp as 2½ chains are sometimes tried, and on tramways of the same gauge curves of one-chain radius can be worked round. At each terminus of the Bessbrook and Newry Tramway (3ft. gauge) there is a loop of 55ft. radius, round which the cars are easily worked in order to avoid the necessity of reversing them; it should be remembered, however, that these cars are of the bogie type. Gradients steeper than 1 in 30 are seldom adopted in this country on railways and tramways worked by mechanical means, and considering that, owing to an unfortunate clause in the Act 31 and 32 Vict., the weight on one pair of wheels of any engine shall not exceed eight tons, it is evident that only light trains can be taken over a gradient of 1 in 30. If anything in the shape of heavy

* A paper read before the Incorporated Association of Municipal and County Engineers at Londonderry.

Digitized by Google

traffic is anticipated, the gradients should not, if possible, exceed 1 in 60.

Cost of Construction.

The cost of constructing and equipping a light railway or tramway has been variously estimated at from £1,000 to £10,000 per mile, and a few tramways have been constructed in England at a cost of about £1,000 a mile, but I think the lowest at which any tramway has been constructed and opened for passenger traffic in this country is £1,800 per mile, the approximate sum at which the Warrenpoint and Rostrevor Tramway, 3 miles 20 chains in length, was constructed. Probably, no light railway has been constructed and equipped in this country at less than £3,000 per mile; perhaps the cheapest line which has come under my notice is a branch of the Cavan, Leitrim, and Roscommon Light Railway and Tramway, from Ballinamore to Drumshambo, which is stated to have cost only £3,100 per mile. The gauge of this line is 3ft.; weight of rail 45lb.; weight of engines 20 tons when empty; steepest gradient 1 in 30, and sharpest curve 250ft. radius. The engines are specified as being capable of taking a train of 100 tons up a continuous incline of 1 in 40 for one-third of a mile, with curves of 10 chains radius.

A few other examples may be given showing the comparative cost, etc., of light railways and tramways in Ireland. The Castlederg and Victoria Bridge Tramway (7 miles 12 chains), 3ft. gauge, cost slightly over £3,000 per mile. The Portstewart Tramway (1 mile 68 chains), 3ft. gauge, cost slightly over £3,000 per mile. Schull and Skibbereen Railway (14 miles)—gauge 3ft., weight of rail 45lb., steepest gradient 1 in 30 for a distance of one mile, sharpest curve 2½ chains—cost £4,000 per mile. When this line was first opened for traffic four engines were provided, one only being of the bogie type, the remainder stiff, which, however, proved very unsatisfactory. Clogher Valley Light Railway and Tramway (37 miles 3 chains)—gauge 3ft., weight of rail 45lb., steepest gradient 1 in 30, sharpest curve (in the town of Caledon) 1½ chains, on private land, sharpest curve 4 chains—cost about £4,000 per mile. Clonakilty Extension Railway (8 miles)—gauge 5ft. 6in., weight of rail 65lb., steepest gradient 1 in 70, sharpest curve 15 chains — cost about £4,500 per mile. Although this line cost such a small sum to construct, it can hardly be classed under the head of a light railway, and it was not constructed under the Act of 1883, but under a special Act.

I should mention that all the above lines are worked by locomotives except the Warrenpoint and Rostrevor Tramway, which is worked by horses, and also that the estimates given include the cost of rolling-stock, except in the case of the Clonakilty Extension Railway, which is worked by the Cork and Bandon Railway for a percentage of the gross receipts.

Method of Construction.

The method of construction is usually pretty much the same for light railways and tramways of the kinds mentioned above. The rails are of the Vignoles section, weighing from 45lb. to 65lb. to the yard. The sleepers for narrow-gauge lines 6ft. by 8in. by 4in., for ordinary gauge 9ft. by 9in. by 4½in.; both creosoted and uncreosoted are used, generally rectangular, but sometimes half round. The sleepers are generally placed 3ft. apart centre to centre, and at the joints 2ft. centre to centre. As the traffic on these lines is not very heavy, the rails will last for a very long period without requiring to be renewed, but the life of the sleepers deserves consideration. Ten years is found a good average life for Baltic sleepers creosoted under pressure, but they will frequently be found sound after being in as long as 15 years. Six years would be a fair average for the same sleepers merely dipped, and five years if unprotected. Scotch fir sleepers will last about five years, and larch about eight years, but larch is not always obtainable. While on the subject of sleepers, I might mention that I had recently to inspect a short narrow-gauge line, on which very light wrought-iron sleepers were used, and they seemed very well adapted for their purpose. The rails are secured to the sleepers by dog-spikes; frequently fang bolts in addition are used at the ends of each rail, and on curves sometimes about the centre of each rail as well. Sole-plates are also occasionally used. Depth of ballast about 12in. below the underside of the sleeper, bottom ballast 6in. quarry shivers, top 6in. gravel or broken stone; gravel is probably the most suitable ballast for light railways, as broken stone makes a harsh and noisy road.

Details of Cost of Construction.

The most important item is usually for permanent way, and this, including fencing, is variously put down for a light railway at from £1,000 to £1,800 per mile. The rails, fishplates, bolts, etc., of course, vary with the market, but as regards the other items of permanent way, uncreosoted sleepers 9ft. by 9in. by 4½in., cost about 1s. 6d. each; laying permanent way, 1s. 6d. per lineal yard forward; ballast pitching and boxing, also 1s. 6d. per yard forward; sod fencing both sides, 9d. to 2s. per lineal yard; and wire fencing, 1s. per lineal yard. Clay cutting is probably the next most important item, and is frequently put down at 1s. a cubic yard for cutting, and 8d. for filling; sometimes cutting and filling are estimated together at 1s. 2d. to 1s. 8d. per cubic yard, and 1s. 2d. a yard will generally be found a very fair price for it. Rock is estimated at 1s. 6d. to 4s. a cubic yard, according to circumstances. Masonry work varies so much that it would be impossible to put an average price on it. Metalling and forming roads and level crossing, 1s. to 2s. per yard super. The above give some idea of the prices at which work is let to a contractor. The actual cost is, of course, in many cases far less. I have known clay, for instance, taken out and tipped at 4d. per cubic yard, and fencing sublet to a labourer at 1s. 6d. per Irish perch.

Rolling-Stock.—Engines, £500 to £1,800 each; coaches, £300 to £500; wagons, £50 to £150.

Objections, etc, to Tramways Running along the Sides of Public Roads.

When the condensation of the escape steam is properly effected, the machinery invisible and the sound from it inaudible, the danger of running a steam-engine along a public road is very much minimised; while, further, if ample room is left for the ordinary traffic, little objection can be raised to the construction of a tramway alongside it. A few minor objections, however, may be raised—for example, the duty of seeing that the line is constructed in a proper manner, and that it is fit to be opened for traffic lies with the Board of Trade, but the onus of seeing that public rights are not interfered with, and that the roadway is maintained safe for traffic, is left to the county surveyor. As, however, the contractor can frequently save a few pounds by taking in a little more of the roadway on one side instead of a strip of land on the other, and the engineer can obtain better gradients by dropping his line a little below the roadway in places, the county surveyor has to exercise constant supervision over the work. Once the contractor has got his line laid down it is very difficult to induce him or compel him to alter it. Another objection to these tramways is that they are frequently raised, to suit the gradients, 2ft. or 3ft. over the road level, and the occupiers of the fields inside the tramway are constantly endeavouring to cart across the line, and in order to do so have to make some sort of an approach on the public road to reach the tramway level, and so raise a dangerous obstruction to the road traffic.

Electrical Tramways.

Electrical tramways may be classified under five heads, according as (1) the conductor is an overhead wire; (2) is laid underground; (3) is a central rail laid on the surface; (4) is a side rail; or (5) when accumulators are used.

The overhead system, which may be subdivided into the span-wire system and the side-wire system, is doubtless the best known in Great Britain. Some of the objections raised to it are the unsightly appearance of the poles, the difficulties at sharp curves and where wires cross, and the possibility of the wires breaking. I understand, however, that the poles recently erected in connection with some continental systems are "things of beauty," and one objection to this system has therefore been got over; moreover, the difficulties with sharp curves and cross-wires have been very much minimised, while the danger of the

Digitized by Google

wire breaking is little more than imaginary. This system will probably be found, as a rule, the most suitable for suburban and rural lines. The underground system will, no doubt, come more into favour for street tramways, but it is an expensive system: a slot of any sort in a street is objectionable, and the difficulty of keeping the tube free from dirt is an objection to it. For light railways or tramways laid on private land, or carried overhead or underground, the central rail is perhaps the simplest and cheapest, but the difficulties of arranging points and crossings, owing to the central rail, are considerable. In particular cases, as in the case of the Portrush and Causeway Tramway, the side rail answers well. The cost of the accumulator system renders it generally prohibitive. Two of the earliest electrical tramways constructed in the United Kingdom were the Portrush and Causeway Tramway, opened in 1883, and the Bessbrook and Newry Tramway, opened in 1885. Both of these tramways have been fully dealt with in papers read before the Institution of Civil Engineers, and it is therefore unnecessary for me to enter into many details regarding them. In both cases the electricity is generated by means of turbines worked by water power. The generating station in connection with the Portrush and Causeway Tramway is some seven miles from Portrush, the starting point of the tramway, while the generating station in connection with the Bessbrook and Newry Tram way is at Millvale, about half-way between Bessbrook and Newry. At both places the arrangements are so simple that only one attendant is required at each station to look after the whole of the machinery, etc.

Portrush and Causeway Tramway.—This line is eight miles in length and 3ft. gauge; the conductor is at the side and of T-iron, weighing 19lb. to the yard, placed about 2ft. 6in. above the level of the permanent way. Contact is maintained by means of brushes projecting from the sides of the cars, and the return circuit is conveyed through the tram rails. The cars are taken from the terminus of the Northern Counties Railway to the commencement of the electric tramway, a short distance out of Portrush, by means of ordinary locomotives.

Bessbrook and Newry Tramway.—This line runs from Newry to Bessbrook in County Armagh, a distance of 3 miles 2 chains. The gauge is 3ft., and the maximum gradient 1 in 50. The conductor consists of a central rail of channel section resting on insulators; at the joints the electrical connection is made by means of bent strips of copper riveted to the channel iron. Where the tramway crosses minor roads the conductor consists of a cable carried underneath the surface, and where the tramway crosses the main road from Armagh to Newry the conductor is carried overhead. The return circuit is through the tram rails, the rails being connected at the joints by wire or copper strips. The motors are of the Edison-Hopkinson type, and are placed on the front of the cars, and the gearing arrangement, although rather complicated, is working satisfactorily. No doubt the practice now being adopted on other lines of placing the armatures on the axles of the cars very much simplifies the working, but I imagine that it must be found difficult to keep the parts clean in such a position, and they are also more liable to suffer from vibration and inequalities in the road.

The rolling-stock consists of three passenger cars, two of which are provided with motors in front, and numerous wagons. The wagons are designed with flangeless wheels, so that they can be drawn by horses from the terminus in Newry to the quays, and these wheels run, not on the tram rails, but on rails placed immediately outside them and at a slightly lower level. Of course, the fact of there being four tram rails, as well as a central conductor, renders the arrangement of points and crossings extremely complicated, but otherwise no difficulty has been experienced in the working of the system. This tramway has now been open for traffic for the past 10 years, and it is satisfactory to note that the cost of working and general expenses have been extremely small.

Time will not permit the author to deal with horse tram ways in our larger towns in Ireland, and he trusts that some member with more experience of these tramways will present the association with a paper on a future occasion.

Conclusion.

The subject of light railways and tramways in this country is a large one, and the need for them is great. Government has dealt liberally with Ireland in the past, and it is to be hoped it will deal still more liberally in the future. Further free grants to the poorer districts, and the issue of loans of 2 or 3 per cent. on a grand jury guarantee in every district, would probably be the means of doubling the tramway system of Ireland in a few years. In order, however, to make the Irish tramway systems popular and useful, it is necessary that the rates charged for the conveyance of goods and passengers should be as low as possible. To enable this to be done, the working expenses must be reduced to a minimum. In this country—at any rate inland—coal is dear, but water is plentiful and can be rendered easily available for the working of turbines or other hydraulic machinery. The author therefore ventures to suggest that the motive power for the working of tramways in Ireland may possibly in the future be obtained most easily by electricity generated by means of hydraulic power, and he earnestly hopes that the close of the nineteenth century may witness the construction of light railways and tramways throughout the length and breadth of his native land.

CITY OF LONDONDERRY.

The following is Mr. J. Christie's report on the estimated cost of plant for the supply of private electric lighting:

Gentlemen,—At a meeting of the Lighting Committee held on June 20 last, I was instructed to report on the probable cost of a private lighting installation. I may mention that I have, during the past winter, drawn up a scheme which, to my mind, would best suit the requirements of this city, embodying all the necessary details of plant and alterations to the buildings, but as you now only wish the approximate cost of such a scheme, it is needless for me to enter into a detailed description of the system which I would propose to adopt until you really decide to go on with the work, so for the present I will confine myself to dealing with the subject chiefly from a financial point of view, and I now submit to you the result of my efforts in the following report. In the scheme which I would propose adopting, I would at first only lay down the supply mains in a limited area where the most probable demand for light and power exists, keeping in view, however, the extension of the system to outlying districts, chief among which is the Waterside. In this report I will deal mainly with the supply to the limited area, but will later on refer to the probable cost of such an extension. In the Waterside, the district consists largely of residences of the better class, many of which would be probable customers, and if a demand for 1,000 to 1,500 16-c.p. lamps could be depended on the extra sum necessary to lay down plant and mains to supply them should be self-supporting; but I may here mention that the return in these outlying districts per lamp connected, owing to the extra cost of distribution over such a scattered area, can never be so high as within the limited area. I would, therefore, consider it advisable to defer any extension outside the limited area until such time as the first instalment of plant had been worked up to a satisfactory basis; at the same time, when designing and laying down the plant, making such provision as shall allow of these extensions being carried out at a minimum of cost when the proper time arrives. The limited area where the supply would be first available would be as follows: along Strand-road and Foyle-street to bridge, up Carlisle-road, Ferryquay-street, Bishop-street, and Pump-street, along Butcher-street, Castle-street, and Richmond-street, down Shipquay-street, to Waterloo-place. Off these mains branches up side streets would be taken to suit customers as they sent in their applications. The first instalment of plant would be sufficient to run 3,500 16-c.p. lamps, or their equivalent, all alight at one time, allowing a suitable margin of spare plant as reserve. From past experience in other towns it has been found that rarely more than 75 per cent. of the lamps installed are ever alight at any one time, so that with this amount of plant we could with safety connect quite 25 per cent. more lamps than this number to our mains, or a total of, say, 4,500 16-c.p. lamps, so upon this number and the average price per lamp per annum, as obtained at other towns somewhat similarly situated, I will base my estimate of works' costs, probable revenue, etc. If a private supply scheme were gone on with, the additional staff, plant, and stores would all have to be run in conjunction with the existing public lighting system, and it would be a most difficult matter indeed to know where to draw the line when allocating the fair share of expenses to each department—

Digitized by Google

the public and private lighting. The only way to overcome this difficulty would be for the Corporation to allow the electricity department for lighting the streets a certain fixed sum per lamp per annum, which we might look upon as revenue, paying all expenses connected with the public lighting by electricity out of this sum, and, if possible, make a small profit, which profit could be set aside as a sort of reserve fund, and used from time to time for extended the public lighting scheme, and gradually do away with the gas lamps. At present we have 170 arc lamps erected. In London and other large towns for similar lamps the supply companies or municipal stations are allowed by the corporations or vestries £26 to £30 per lamp per annum, but as we do not require to run our lamps for quite such long hours, I would say a fair price for this Corporation to allow the electricity department would be not less than £20. 10s. per lamp per year. This would work out at about £3,500 per annum. My estimate of the works cost (see report of December 20, 1894) was £2,300, to which must be added, say, £1,200 for repayment of loan, interest, etc., making a total of £3,500 for street-lighting by electricity. Owing to the increased economy and efficiency of boilers, staff, etc., due to the working of the public and private lighting schemes in conjunction, I reckon we will be able to reduce this sum by £300 a year. I think if such a result were attained it would only be fair to credit the department with this saving, utilising it in the manner I have already suggested. To put down the private supply plant of the capacity I propose, and do everything in first-class style, would necessitate an outlay of some £20,000, which would be made up as follows :

Buildings, including offices, house, etc.	£1,750
Boilders, pipes, etc.	2,750
Engine-room plant	6,400
Mains, etc.	7,500
Instruments, meters	600
Contingencies	1,000
	£20,000

To provide for the Waterside and outlying districts would necessitate a further expenditure of about £6,000. It would, therefore, be advisable to borrow £26,000, at first only spending the £20,000 on the limited area, and have the £6,000 in hand for future extensions, without having to call a second Local Government Board enquiry, when such extensions became necessary. An approximate balance-sheet of the undertaking, assuming all the lamps were taken up—and this could reasonably be expected within the second year of operation—would be as follows :

REVENUE.

Public Lighting.—170 arc lamps, at £20. 10s. per lamp per annum		£3,485
Private Lighting.—4,500 16-c.p. lamps, using 30 units per lamp per annum, at 5d. per unit =135,000 units		2,812
Guildhall Lighting.—Lighting hall and clock		110
		£6,407

EXPENDITURE.

Public Lighting.—172* arc lamps, including all costs, at, say, £18. 12s. 3d. per lamp per year... * Two extra lamps in station, testing, etc.				£3,200
Private Lighting.—Works costs, generating 135,000 units, at 2·47d. per unit, made up thus :				
Coal.....	·75d. per unit	£420	0 0	
Oils, etc....	·25d. ,, ...	140	12 0	
Wages.....	·97d. ,, ...	550	0 0	
Repairs ...	·50d. ,, ...	281	5 0	
	2·47d.	£1,392	17 0	
Proportion rates, taxes, etc.....		75	0 0	
Management and office expenses.....		250	0 0	
		£1,717	17 0, say	£1,720
Guildhall Lighting.—Expenses for clock and hall lighting				50
				£4,970
Income				£6,407
Outlay				4,970
Profit				£1,437
Less assumed profit on street-lighting				300
Profit				£1,137

after paying all works' costs. This sum, £1,137, represents a sum of 5·68 per cent. on the capital outlay out of which to pay interest, etc.

Gentlemen, I have not in any way tried to present this scheme to you in too prosperous a light, but have simply given you figures based on averages which have been actually obtained, and in many cases exceeded in other municipal electricity supply stations in this country, and there is no reason why Londonderry should not do equally well. The success of the undertaking is simply a question of demand, and, if every citizen having premises within the area of supply will only look upon the scheme as an enterprise in which he is indirectly a shareholder, and encourage it by contributing to its success by becoming a consumer, no matter how small a one, I have no hesitation in saying that these figures which I have given you will be more than realised, whilst the public will obtain a better and a more healthy light, and also a source of motive power, at a cost which certainly will not exceed the present price of gas, considering the many increased advantages of electricity.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Alexandria.—The municipal authorities of Alexandria, Egypt, invite applications by October 1, 1895, for the concession of the tramway lines from St. Catherine Place, through the outer boulevards, to the projected abattoirs at Mex, with a branch line. Security £E1,000.

Bedford.—The Urban Sanitary Authority invite tenders for the supply of vulcanised rubber cables, in accordance with the specification which can be obtained from Mr. T. S. Porter, clerk to the Authority, on payment of a fee of 5s. for each copy. Sealed tenders, endorsed "Electricity," to be delivered at his office not later than September 4.

Braila.—The Municipal Authorities of Braila, Roumania, invite tenders by October 2 for the construction and working of a system of electric tramways in the city. Provisional security, 10,000f. This contract was originally fixed for July 29. Tenders are further invited by the Municipal Authorities of Braila for the lighting of the city by electricity or by electricity and gas. Provisional security 10,000f.

Great Yarmouth.—Tenders are invited for the supply of coal to the electric light station for 10 months from September 10, for the Electric Lighting Committee. Specifications can be seen and forms of tender can be obtained at the office of Mr. J. W. Cockrill, borough surveyor. Tenders, on the form and in the envelope supplied, are to be delivered at the office of Mr. T. M. Baker, town clerk, before noon on September 3.

Chepping Wycombe (Bucks.).—The Urban Sanitary Authority for this borough are prepared to receive tenders from public companies for working the electric order obtained by them within the borough for a term of years and upon approved conditions. Tenders are to be delivered by noon on October 14 next, at the office of the town clerk, High Wycombe, where a copy of the electric order may be seen and further particulars obtained. The Authority do not bind themselves to accept any tender.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

Oldham.—The Baths Committee of the Oldham Corporation are prepared to receive tenders for supplying and fixing wires, fittings, etc., for lighting by electricity a portion of the Central Baths, Oldham. Specifications can be obtained from Mr. S. Willmott Newington, borough electrical engineer, Gas-street, Oldham, on payment of 10s. 6d., which will be refunded on the return of the specification, accompanied with a *bond fide* tender. Tenders, endorsed "Tender for Wiring," must be sent to the office of the town clerk, Town Hall, Oldham, before noon on September 11.

London, W.—The Hammersmith Vestry invite tenders for complete schemes for public and private lighting, and for the supply of motor power in that portion of the parish of Hammersmith described in the provisional order as the compulsory area. Memoranda of instructions, with a map of the district, may be obtained from Mr. H. Mair, surveyor to the Vestry, between the hours of nine and five, Saturdays nine and one, on payment of a deposit of £10, which will be returned to persons sending in a bona fide tender. Tenders are to be delivered at the meeting of the Vestry, at the Vestry Hall, at 6.30 p.m. on September 4.

Stafford.—The committee of the Staffordshire County Infirmary invite tenders for wiring and fitting the infirmary for electric light. Tenders, sealed and addressed to the secretary, Staffordshire County Infirmary, Stafford, and endorsed "Tender for Electric Lighting," must be received by him not later than noon on September 14. Copies of the specification, with form of tender attached, can be obtained from the secretary on payment of £1, which will be returned on receipt of a *bond fide* tender ; and plans may be seen on or after Monday, September 2, at the infirmary, or at the offices of the engineers, Messrs. Kincaid, Waller, and Manville, 29, Great George-street, London, S.W.

Sunderland.—The Corporation of Sunderland are prepared to receive tenders for the following : (*a*) high-tension and low-tension concentric cables ; (*b*) cast-iron pipes, and box frames and covers ; (*c*) stoneware casing, boxes, and bellmouth protectors ; (*d*) high-

Digitized by Google

tension transformers for alternating current; (*e*) meters for alternating current. Specification, conditions of contract, and form of tender may be obtained on payment of £1. 1s. at the office of the borough electrical engineer, Electric Supply Station, Sunderland. The deposit will be refunded on receipt of the specification and conditions of contract with a *bonâ fide* tender. Sealed tenders, addressed to the chairman of the Highways Committee should be delivered at the town clerk's office by 6.30 p m on Friday, September 13.

Queenstown (Ireland).—Tenders are invited by the Queenstown Town Commissioners for the lighting of Queenstown by electricity (private as well as public) as per report and specification of Mr. R. Hammond, M.I.E.E., Ormond House, London. Tenders are also invited as follows: the contractor to provide the capital for the due erection of the works and maintenance thereof as per above plans and specifications, on being guaranteed the public lighting, and a stipulated number of private lights (to be agreed upon), the Commissioners having the right to purchase within a specified period. Plans and specifications are deposited at the Hall, Queenstown, and can be inspected there between 11 and 2. Tenders must be lodged with the town clerk, Queenstown, marked "Tender for Electric Lighting," by 2 p.m. on September 16. Further particulars and conditions to be had on application to Mr. James Ahern, town clerk, Queenstown.

RESULTS OF TENDERS.

Belfast.—The tender of Messrs. Wormald and Co. has been accepted by the Corporation for covering the exhaust-pipes of the engines at the electric light station.

COMPANIES' MEETINGS AND REPORTS.

NORTH STAFFORDSHIRE TRAMWAYS COMPANY.

The twenty-ninth ordinary general meeting of this Company was held on Tuesday at the Guildhall Tavern, Gresham-street, E.C., Mr. W. J. Carruthers-Wain, A.I C.E, presiding.

The Secretary (Mr. J. G. B. Elliot) having read the notice convening the meeting,

The **Chairman** said: With regard to the figures for the half-year, I may say we are not singular in not showing a good result. Our friends, the North Staffordshire Railway, are also suffering from a decreased dividend, and as an indication of the scarcity of trade in the district at the beginning of the year I may tell you that in the half-year they moved 170,000 less tons than in the corresponding half of last year. Then, again, they naturally, like ourselves, met with difficulties in carrying on traffic in the face of one of the most severe winters, I suppose, which has ever been experienced. Under such circumstances you cannot diminish your service—at least you ought not to. You must keep faith with the public so far as you can, and although your traffic receipts are very much smaller, your expenses are not only on the ordinary scale, but have to be kept up on an extraordinary scale, in order to keep your line working. Had we been dealing with ordinary conditions, the increased mileage would have brought you a very large additional amount of money with very little, if any, additional expense except that which is necessary owing to the increasing age of the line and the engines. The first duty of the directors must be to keep your line and rolling-stock in a first-class state of repair. If they did not endeavour to do that as far as possible they would have constant difficulties with the Board of Trade and the local authorities, and it is such difficulties that we are endeavouring to avoid, especially having regard to the fact that the seven years' steam license expired in May last, and naturally we desire its renewal, and have to take all necessary measures and precautions to ensure the continuance of your traffic. Well, that we have done, and, I believe, successfully. Respecting the distribution of the profit, I do not suppose anyone will object to that. With reference to the vexed question of Longton, which has been so frequently before these meetings, I am very pleased to tell you that as a result of the amount of light thrown upon the subject during the proceedings of the Light Railways Committee, of which, as president of the Tramways Institute, I was a member, the Board of Trade are likely to meet the Longton Town Council, and little differences will be smoothed over by judicious consideration on both sides The Longton lines will, I believe, before long, not only be allowed to be worked, but valuable extensions of them will be made by the Corporation at their own expense, and I hope, having regard to the good relations that exist between us and the Longton Corporation, that we shall be able to work those lines for your profit. That will be a great satisfaction to me, seeing that so much of your capital has lain dormant there for so many years—in fact, at one time it was looked upon as hopelessly lost. If no other good comes out of the Light Railways Committee, that, at any rate, will be something in your favour. Then I come to paragraph 6, which is perhaps the most important paragraph in the report. You can quite understand, speaking with all deference and all due respect to the constituted authorities, that they have naturally, and I am bound to say I do not think improperly, a desire when they have an opportunity to take advantage of it, at any rate to some extent. The expiration of our steam license in May last was an opportunity for them to say, "Now, although we are very well satisfied," and that is what they did say, "with the manner in which you conduct steam traffic, yet steam traffic is not likely to go on for ever. We want you to take into your most serious consideration the question of the adoption of some improved motor upon these lines." Naturally we said in reply that we are very well satisfied with steam as it is. Steam has afforded enormous convenience to the inhabitants of this and many other districts. In this district it has been worked with less complaint than in any other in the kingdom, and that it has been exceedingly well worked is testified by the fact that when the Tramways Institute of Great Britain and Ireland, which comprises some of the leading companies in the kingdom, visited Stoke-upon-Trent in April last, they expressed their unbounded satisfaction with the manner in which the steam tramway was conducted in the district. Be that as it may, a great many people consider that steam traction is a thing of the past, or will not long survive, and that other forms of traction must come to the front. Of course there is no doubt that, having regard to the severe gradients with which we have to contend in North Staffordshire, the only system which can possibly be adopted there would be either the cable or electricity by means of overhead wires. So far as the cable system is concerned, the traffic is not great enough for that, and the curves are tremendous. Therefore the difficulties of working a cable on a single road would be exceedingly great, and the expense would be tremendous. Consequently, the directors are forced to consider electricity by means of overhead wires. We, therefore, suggested to the Town Council that if they desired us to give up the use of steam and adopt electricity, they should give us an extension of our lease in order to give us time to recoup ourselves for laying down such an installation. We pointed out that it was perfectly impossible that in the seven years or thereabouts that remained to the Company now of the original 21 years for which that obsolete and, I might say, absolutely stupid Act of Parliament, known as the Tramways Act, 1870, granted the company powers, it would be impossible for anyone to advance money or undertake to work a line for a limited time like that. I am happy to say that the local authorities agree that if we do put up an installation of this character they are prepared to extend our lease for a considerable period; or, rather, to put it in a more technical way, they are prepared not to exercise their powers to purchase under Section 43 of the Tramways Act, 1870, for a very much longer period than we at present enjoy. I may be wrong, but I think that this is the best way in which to go to work with local authorities. They want something from you, and you naturally ask something from them, and if you can agree upon the principle I do not think there will be very much difficulty about the details When a proper scheme is matured for the working of the line by electricity, and when all necessary preliminary arrangements have been made by the local authority, and before anything is done which will commit you absolutely, you will be called together, and the fullest details will be laid before you, and your approval will be asked to any agreements which we propose to enter into. Whatever further steps are taken with regard to the extensions, before anything is done which would commit you in any way to them financially, or even in the improvement of the permanent way, your opinion will be asked, and you will be, as you always have been, taken into our fullest confidence, so that we shall be able to know that in what we are doing we have the assurance of your fullest support. Before I sit down, I would like to say one word on a personal matter to which I will only allude in the briefest possible terms. There are men whose position sometimes even in a small way marks them out for personal attack. I allude to this simply because some attacks sometimes find their way into newspapers circulating in the locality which this line serves To honest criticism from intelligent critics no one can possibly object. On the contrary, well directed, intelligent criticism is very useful; but I consider contemptuously the captious, cavilling criticisms and the scandalous scurrility of people whose insolent ignorance is only equalled by their malicious mendacity. I beg to move the adoption of the report and accounts.

Alderman E. J. Hammersley, J.P., seconded the motion, which was carried after some discussion.

A dividend at the rate of 6 per cent. per annum on the preference shares, and 3 per cent. per annum on the ordinary capital for the half-year was declared, and a cordial vote of thanks was passed to the chairman, directors, secretary, manager, and staff.

SOUTH STAFFORDSHIRE TRAMWAYS COMPANY, LIMITED.

The fifth ordinary meeting of this Company was held on Monday at the Cannon-street Hotel, E C.

Mr. W. S. Schuster moved the adoption of the report, which, he said, covered a period of two years' working, although the present directors had only had the management for six weeks. He stated that the contract made with the Electric Construction Company before the present Board came into power they had repudiated entirely, on the ground that it was so one-sided that no court would uphold it. Certain persons wanted the Company wiped out, but the present directors had resisted these attempts, and up to the present date the court had supported the directors' action.

The report was adopted.

Hermite Process of Sanitation.—The War Office have instructed Messrs. Paterson and Cooper to proceed with the erection at Netley Hospital of the Hermite sanitation plant, the cost of which has been provided for in this year's parliamentary estimates. The Corporation of Cape Town have also ordered a plant for producing electrolysed sea-water with a view to the Hermite process being applied to the sanitation of the place.

Digitized by Google

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £2 945.

Bromley.—The Urban District Council have held a meeting at which, in answer to Mr. Peill, the Chairman replied that the Council was in communication with the syndicate which proposed to buy up the Council's powers under the provisional order for electric lighting.

Pneumatic (Self-Closing) Tube Company, Limited.—This Company has been registered by Jordan and Sons, Limited, 120, Chancery-lane, W.C., with a capital of £50,000. to carry on business as manufacturers of and dealers in indiarubber and other like gums, also as factors, merchants, etc

Partnership.—Messrs. Percy H. Tewson and Roland H. Streatfeild, A I.E.E., who were formerly with Messrs Laing, Wharton, and Down, have entered into partnership as electrical engineers and contractors, and will trade under the name of Tewson and Streatfeild, at 35, Bucklersbury, London, E.C.

Chloride Electrical Storage Syndicate.—We have received a copy of the third edition of the catalogue, issued in handy pocket-book form, which is published by the Chloride Electrical Storage Syndicate, Limited, of Clifton Junction, Manchester, and 16, Victoria street, Westminster, at the price of 1s.

International Cable Company.—By order of Mr. Justice Stirling, a final dividend on the shares in the International Cable Company, Limited, at the rate of 5s. 3¾d. per share, will be paid at the offices of Mr. F. S. Lucey, the official liquidator, 15, George-street, Mansion House, on and after Monday, 26th inst.

Gilmorton (Leicester).—At the Parish Council's last meeting the clerk read correspondence with the Postmaster-General as to a telegraph office in the village, and the guarantee required. As it was a matter which concerned other parishes, the Council decided that the matter should be left to private enterprise.

City and South London Railway.—The returns for the week ended August 25 were £875, compared with £878 for the corresponding period of 1894, being a decrease of £3. The total receipts for the half-year 1895 are £6,883, as compared with £6,941 for the corresponding period of 1894, being a decrease of £58.

Coalville.—At the last meeting of the Urban District Council the clerk read a communication from the Local Government Board asking for guarantors for the increased postal facilities at the post office at Ratby. As there was no mention in the letter of telegraphic facilities, which had been applied for, the Council instructed the clerk to write to the Department enquiring why no reference was made to the application for increased telegraphic facilities.

The Tudor Accumulators.—Mr. A B Pescatore, of Haworth's-buildings, 5, Cross street, Manchester, informs us that he has acquired from Mr. Tudor the sole concession for the United Kingdom of his system of accumulators, and that he has established works for their manufacture at Dukinfield, near Manchester. It is stated that more than 5,000 batteries of Tudor accumulators are working in different parts of the world; among which 60 have an output exceeding 150 h.p., and several an output exceeding 500 h.p.

Loughborough.—At the last meeting of the Town Council a letter was received from the Local Government Board with reference to the Island House Park loan. The sub-committee reported that as land would shortly be required for an electric lighting station and other public works, it would be folly to sell any portion of the area as surplus land, with the certainty that other land would have to be purchased in the near future in a less convenient position, and possibly at a larger price, and that until the whole area was thus occupied the part not otherwise utilised would be used as a pleasure ground.

Llandudno.—At the last meeting of the District Council a letter was read from the secretary to the Llandudno Electric Supply Company, Limited, referring to the order which the Council have recently obtained for the supply of electricity within their district, and enquiring whether the Council propose to carry out the work themselves or whether they would feel disposed to allow it to be done by his company, and if the latter course be preferred, on what terms. It was decided that the question be referred for consideration to a committee consisting of the chairman of each standing committee.

Llanelly.—A meeting of the Llanelly Chamber of Commerce has been held, at which it was stated that electric lighting was a question which has agitated the mind of the public and the Borough Council of Llanelly for several years, and the action of the Llanelly authority during the past year impressed the Council that an address by an expert would be instructive. Mr. J. C. Howell, electrical engineer, a member of the Chamber, and a gentleman thoroughly qualified to speak on the subject, was accordingly invited to read a paper. He cordially responded, and delivered a valuable and interesting address on the subject of "Electrical Energy."

Leamington.—At the monthly meeting of the School Board a letter was read from the Midland Electric Light and Power Company, stating that they proposed to run a cable for the supply of electric light along a portion of Dormer-place at their own expense if they found that the demand was sufficient to justify them in so doing. They would therefore be glad to know if the Board would adopt the light in their offices. The charge was 8d. per unit. Mr. Barrett moved that the clerk be empowered to obtain an estimate, and that it be submitted for consideration at the next meeting of the Board. After discussion the motion was carried *nem. con.*

Situations Vacant.—An engine and dynamo man, accustomed to the work in an alternating-current station, is required. Preference will be given to one who has served his time as a fitter. Wages £1. 12s. per week. Apply in writing to the town clerk, Southport.—A large West end firm require a very competent man to take entire charge of a City branch. Must be thoroughly well up in gas and electric lighting, heating by gas, water, and steam, and ventilation work. Only those need apply who have had good experience in above branches of work One who has been employed in the City preferred. State references and salary expected to Box 1021, Sell's Advertising Offices, London, E C.

The Telephone Service.—At the monthly meeting of the Council of the Halifax Chamber of Commerce the report of the General Purposes Committee on telephones was read. It stated that out of 211 circulars sent out as to the telephone service 70 replies had been received. All were unanimous in saying that the present charges were too high, and suggesting £5 as a more satisfactory charge. The complaints as to inattention were numerous. In many cases communication with other towns was delayed sometimes as long as 40 minutes. Several suggested that the annual rental should include all trunk charges, especially to the neighbouring towns. It was decided that along with Dewsbury and other Chambers who were taking this subject up that the utmost be done to remedy these grievances.

Westfield.—Councillor Tuppenney, J P., is taking active steps to procure telegraphic communication for Westfield. He has addressed a letter to the Parish Council, in which he says: "At the last meeting of the Battle District Council an application was made by the Post Office authorities for permission to place poles by the roadside from Doleham railway bridge *en route* to Brede, to carry a telegraph line from Hastings to the former place The application was of course, granted as far as the Council have jurisdiction. I beg to call your attention to the fact, hoping that you will place the matter before the Parish Council with a view to a representation being made to the Postmaster-General that, as the line will be within a comparatively short distance of our own post office, telegraphic communication could at a small cost be conferred upon Westfield."

Birkdale.—At the last meeting of the District Council attention was directed to an application, which had been referred to the law clerk, that was made by Mr. Buckley, of 6, Westcliffe-road, to allow him, in case the Southport Corporation brought the electric light to the Birkdale boundary, to put a small private cable from the Corporation cable to his house. Mr. Buckley added, in his application, that he would, of course, move the same whenever the electric light was adopted by the Birkdale District Council. The Law Clerk said the matter was one which required very serious consideration. He could not tell when the electric light would be adopted in Birkdale, and there were matters concerned with the rebate on the gas and other things to be considered. It was not a matter entirely for him; it was more for the committee to make their own terms, and he could then draw up an agreement. Mr. Buckley would very likely not agree to it, and at any rate he should want the help of the committee.

Bath.—"With reference to the 'partial failure' of the electric light, which led to a debate at the Surveying Committee," states a note writer in the *Bath Chronicle*, "I am told by Mr. Metzger, the company's manager, that the matter is easily explained. It seems that the contract for the supply of carbons having run out, the company were anxious that the illuminating power of the new carbons should be such as to satisfy the committee, and to this end five different kinds of carbons were tested in the street lamps all the lamps being trimmed alike to obtain a fair result under the proper conditions, and Mr. Gatehouse was asked to report on their qualities. These tests had been made for a fortnight previously, but unfortunately the quality of the carbons used on Saturday and Sunday last was below the standard, although their price is the highest of all. It will be seen, therefore, that the company acted with the best intentions, and purely with a view to obtaining the best possible light."

Kingswood.—A meeting of the Urban Council has been held, at which a long letter was received from the firm who have taken over the electric lighting of Kingswood from Messrs. Parffitt advising several alterations and private lighting under the Council's contract. The Chairman said that it was a matter which called for very careful handling. Of course, there would be objections raised to any alterations of the present contract, and they were in the dark as to the details. They could not have private house electric lighting very well from the overhead wires, and therefore he advised that a small committee should be appointed to investigate the matter. Members might have observed, he said, that the light was very good on the previous night on the occasion of the flower show. Mr. Weight remarked that this only showed that a stronger light could be put on if the company wished. The chairman, vice-chairman (Mr. A. J. Bridges) and Messrs W. T. Howes, S. Burchill, and A. J. Evans were selected as a committee.

Dover.—A meeting of the Town Council has been held at which a letter was read from the electric light company, referring to the statement of Councillor G. Mowll at the previous Council meeting to the effect that the lamps in King-street and Bench-street were placed in the worst possible positions, and pointing out that the responsibility of the position did not rest with them, as the sites were chosen by the late surveyor very much against the advice of their officials. Councillor G. Mowll complained that the company

Digitized by Google

had not made this application before. The late surveyor had, in answer to a question put by himself, denied having anything to do with fixing the lamps. Alderman Adcock suggested that the lamps should be altered. As the late surveyor had fixed the present position, the Council would have to bear the cost. He moved that the matter should be referred to the Town Ward Lighting Committee. The motion was carried. A local paper states that it understands that negotiations are in progress between the Harbour Board and the electric light company for the supply of electric current to obtain power for driving cranes on the Admiralty Pier to transfer baggage to the boats. The necessity for a more rapid transference of the luggage is being at length recognised by the Harbour Board, but whether the cranes will be worked by electricity or not they will certainly be erected.

Brussels.—The report on the electric and gas lighting of the city has just been presented to the Municipality, and it is stated that the sales of gas for lighting amounted to 639,935,000 cubic feet, a decrease of 17½ millions, which was exactly what had been anticipated from the supply of electric light from the municipal electric lighting works. The station, the construction of which was resolved upon in 1892 at a cost not to exceed £100,000, was started on November 3, 1893. The station had three boilers of 2,500 square feet heating area, two 500-h.p. engines, four dynamos of 143 units, and a battery of accumulators of 140 cells to give a current of 350 amperes for 10 hours. As it was obvious that another engine would be required, one of 500 h.p. was ordered in October, 1894, and put in in February, 1895. Another station is in course of construction, a smaller one, for a local demand. At December 31, 1894, the capital outlay had been £87,873. The works are being run in the meantime by the India Rubber, etc., Company on the town's account. The cost of production, distribution, and public lighting was £3,347, and the receipts £5,862, leaving a gross profit of £2,515. This corresponds to 2·86 per cent. on the capital outlay at December 31, 1894; or, not taking the gratuitous supply for municipal lighting into account, 3·64 per cent. The Board of Trade unit cost 3 36d. The mains laid were 8¾ miles, and the feeders 11,900 yards. Number of 16-c.p. lamps, 11,655. The maximum output, on December 22, was 2,115 amperes, corresponding to 4,200 lamps, or 36 per cent of the lamps put up. The average price paid for current was 7·92d. per Board of Trade unit. The price was at first 9 6d., but was reduced to 7·68d. on August 6 last. The current used by the Hotel de la Ville and the King's House is charged at 4·8d. The public lighting comprises the lighting of the Grand Place by two lamps of 20 amperes, and the lighting of the Park in summer by 32 lamps of 12 amperes and two of eight amperes.

Blackpool.—With respect to the electric lighting extensions, the *Blackpool Gazette* says: "In view of the difficulty which we are assured has been experienced in fulfilling all the demands for current, the proposal to extend the electric lighting works does not come as a surprise. But we were certainly not prepared for an extension which will increase the capital account of the works half as much again as it stands at present. It appears at their meeting the Electric Lighting Committee decided to recommend an addition to the buildings, so that two new boilers and a couple of new engines may be erected. As this little order is to cost no less than £30,000, it is interesting to learn that the output of electricity will be thus increased by 300 kilowatts. If the working of the electricity department were satisfactory, we should not demur for one moment. In the ethics of sound business enterprise, an increased trade is synonymous with increased profits. But as we have repeatedly pointed out, there is excellent reason for doubting that the department is even paying its own way; and in this case it looks like increasing the outlay to fritter away more quickly the money of the ratepayers. Anyhow, the recommendation will give the chairman of the committee an opportunity of clearing up some of the points we have latterly raised, and we hope any explanation he cares to give will have particular bearing upon the present system of management." "Nemo," writing to the same journal, says: "It is reported that the Electric Lighting Committee has recommended that another small sum of £30,000 be spent in extensions to the works for next season. Is it necessary to spend so much more? I say most decidedly, 'No.' We have in the shed at the present time five boilers, of which three are 28ft. long by 7ft. diameter. The other two, I am told, are larger boilers. These are tested to work at 140lb. per square inch, and they work at the present time at 120. Each of these boilers will drive 500 i.h.p., which gives us a boiler power of 2,500 i.h.p. Now we are told that it is necessary to put in two more boilers. Coming to the engines, we find that in 1893, when the works started, the engines were stated to be one engine of 200 i.h.p, two engines of 100 i.h.p. each, and three engines of 60 i.h.p. each. About 12 months since another of 400 i.h.p. was put in, making a total of 980 i.h.p. This is how we stand at present: one shed, 150ft. by 50ft, containing seven engines, to get a kilowatt capacity of 440. This could be got with three engines and three boilers, and one-half the space occupied at the present time."

The Mersey Railway.—Mr. Charles Rettie, in a letter to the *Journal of Commerce*, says: "I read the other day the account of the Mersey Railway Company's half-yearly meeting, and perhaps you will allow me to refer to it, especially as I am interested in the "rapid transit problem" as applied to our great centres of industry and commerce. The Mersey tunnel has been a great boon to Birkenhead and Liverpool, and has opened up the Wirral district of Cheshire so that people can get to their places of business much more quickly than before. A very good point was raised at the recent meeting about the fares. It is very widely known that in almost every town in Canada and the United States they have a universal fare of five cents any distance on all the tramways and elevated railways, and not only that, in many places, such as Montreal, they have transfer tickets—that is, you could go from the Dingle to West Derby, changing at Lime-street, for 2½d. We have a good example of this universal rate here in connection with the penny 'buses running from the Pierhead to Prince's-road. On the average, there are 27 'buses running each day, nine of which are Mason's, and they carry between them an average of 9,720 each day, not counting the number of passengers the trams carry on the same route. My argument is this, if they can run the cars in America at a big profit, where the working expenses are far greater than in this country, and not only that, but first cost is greater, wages higher, and smaller populations than we have, surely we can run the cars in this country, where everything is so cheap, and charge a universal fare of 1d. any distance. The population of New York is about two millions, that of London five millions, yet the New York elevated railway carries three times the number that the Metropolitan Underground Railway carries, and pays twice as much. The Mersey Tunnel, I will admit, has had innumerable difficulties to overcome, and very heavy working expenses to meet, but the directors will not get their money back by a policy of big fares. I consider the chairman's remarks on electricity very unfair, amusing, and uncalled for. I do not know who the electrical experts were. The chairman only has to open his eyes and see for himself, without experts, the revolution electricity is working in railroading, especially as applied to local railways, not only as regards light railways, but on heavy roads where the heaviest rails are used all over the world. The steam locomotive, when compared with the electric locomotive, has not a leg to stand on; whether for express work for long distances, or for pulling a heavy train up a steep gradient, the electric locomotive is the best. It is a well-known fact that a locomotive burns about twice as much coal as a stationary engine similar to what is used in our large mills, and that is the reason that electricity has the pull over steam for traction purposes. By means of large, highly economical engines and boilers, with the aid of mechanical stokers, etc., and then transforming the power into electricity by means of dynamos, losing about 10 per cent. in the transmitting or converting of the power, and then transferring the current to the rails, which is picked up by the cars as they run along, losing a little more power in the transmitting of the current, but not sufficient to take any notice of—this is the reason that electric locomotives are more economical than steam locomotives. Another advantage of the electric locomotive is that it can go up a grade better; it has the same power on a hill as on the level, but not so with steam locomotives, as they lose all their power on a hill, when it is most wanted. Another important advantage is there is no smoke or smell, and as no fire or draught is required for the electric locomotive it can be boxed in, so they can run at a great speed without any risk to the driver, one of the principal drawbacks to the racing on the East Coast. Another advantage is that it takes less labour to run on an electric line, as everything runs so smoothly with very little manipulation, and does not require skilled labour to run the cars."

The Projected Derby-Ashbourne Electric Railway.—A large number of influential landowners and others in Derbyshire who have long been impressed with the great necessity for improved railway communication between Derby and Ashbourne manifest great inrerest in the proposed construction of a light (electric) railway between those towns. Mr. John Shaw, jun., of Derby (with the assistance of Messrs. Dickinson, of Birmingham, engineers, well known in equipping and working the South Staffordshire Electric Railway), has produced a scheme for the construction of this light railway, and the proposal has already met with much favour alike from the landowners, farmers, and others in the district. The question of better railway accommodation and communication between the towns of Derby and Ashbourne, and also the opening up of the districts lying between the two towns has long been discussed, and various schemes for a railway have been proposed, but they have all been abandoned on the ground of the initial cost, and, consequently, the improbability of the undertaking paying any interest as a commercial speculation. The prime cost of the railway equipped in the ordinary way was estimated at from £30,000 to £50,000 per mile. Consequently such a railway running from Derby to Ashbourne would cost from £600,000 to £800,000, whereas to build and work a light (electric) railway on the proposed overhead electric system, had been amply proved to be the cheapest and most suitable in the case of the Derby and Ashbourne line. The cost of running per car mile by the overhead system, including all expenses, with the exception of guard's wages and maintenance of permanent way, is 4·06d., as against 8·57d. by steam. It is proposed that the line should be connected with the existing Derby tramway, which terminates on the Ashbourne-road, and thence it would run through the parishes of Mackworth, Kirk Langley, Brailsford, Ednaston, Osmaston, Compton, into the town of Ashbourne, terminating near Compton Bridge. On only one portion of the proposed line is there really a stiff grade, and that is for about one mile at the Ashbourne end, but there will be experienced no difficulty in getting over this. It is suggested that the line should be laid on the western side of the high road, through nearly the whole length, as there is ample room, but through the villages it would probably have to run down the centre of the roadway. The permanent way would be laid at a cost of about £1,000 per mile. Paving would only be laid where absolutely required by the authorities, and in all probability it would only be insisted upon through the villages and a small portion at each end of the line in Derby and at Ashbourne. Electric signalling would be adopted to enable the crossings to be

Digitized by Google

placed at as great a distance as possible from one another. Turn-outs and fixed stopping places will be made where necessary, but a car could stop anywhere to take up or to set down passengers. If the cars on the proposed railway are run at a maximum speed of 15 miles per hour the journey could be completed in an hour, thus showing a saving of time between the light railway and the ordinary railway on the North Stafford line. The rolling-stock necessary for a line of this kind consists of motor cars, trailers, and goods cars. A motor car would have to be equipped with motors of 20 e.h p. each. These cars would cost about £600 each, and trailing cars, which would only be used in summer, would cost about £200 each, while the goods cars, specially fitted, would cost about £100 each All the cars would be lighted by electricity, and the gross rough estimate, showing the entire cost of the line, cost of permanent way, including cost of materials, laying, etc., is estimated at £62,300 It is difficult, of course, to estimate what the traffic on such a line would amount to, but some years ago when a line was projected and surveyed between Derby and Ashbourne, the number of passengers arrived at was about 100,000 per annum. Mr Shaw in his scheme points out that if this number of persons could be carried for the low sum of 1s. 6d. per head (return fare)it would give a revenue of £7,500 per annum for passenger traffic alone. With regard to goods traffic, Mr. Shaw next points out that it would enable farmers in this important agricultural district to attend markets more frequently, besides enabling them to send in their milk and dairy produce at reasonable rates and without the laborious road journey which at present occupies a whole day. This scheme of light railway between Derby and Ashbourne has already received the sanction of a large public meeting of landowners and others, and a representative committee has been formed. It is the unanimous opinion in Ashbourne and the district that the light railway will be an unqualified success, and that it will tend to improve somewhat the agricultural drawbacks of that particular neighbourhood.

PROVISIONAL PATENTS, 1895.

AUGUST 19.

15529. **Improvements in electrical time-switches.** Arthur John Wheatley, 8, Highstreet, Harborne, near Birmingham.

15547. **An improved method of operating electric locomotives, tramcars, and the like, and apparatus therefor.** John Augustine Kingdon, 29, Marlborough-hill, St. John's Wood, London.

15563. **Improvements in the formation of electrodes for use in primary and secondary batteries.** Ludwig Epstein, 28, Southampton-buildings, Chancery-lane, London.

15564. **An improvement in electro propulsion of vehicles or vessels.** Ludwig Epstein, 28, Southampton-buildings, Chancery-lane, London.

AUGUST 20.

15664. **Improvements in electrical apparatus for railway signals actuated by passing trains.** Siemens Bros. and Co , Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

15686. **Improvements in electric railways.** William Phillips Thompson, 6, Lord-street, Liverpool. (James Francis McLaughlin, United States.) (Complete specification.)

15695. **Improvements in electrically-propelled carriages.** Ernest John Clubbe and Alfred William Southey, 53, Chancery-lane, London.

15703. **Improvements in electric cables.** George Gatton Melhuish Hardingham, 191, Fleet-street, London. (The firm of Felten and Guilleaume, Germany.)

AUGUST 21.

15722. **Improvements in the formation of thin plates intended to be subsequently assembled as in certain electrical and like constructions.** Walter Thomson and William Routledge, 3, St. Nicholas-buildings, Newcastle-on-Tyne.

15736. **Improvements in insulating wire for electrical purposes.** Walter Patterson, 218, Goswell-road, London.

AUGUST 22.

15787. **An improved electric connecting device applicable to electroliers, electric light standards, brackets, and the like.** Robert Walter Braham, 60, Red Lion-street, Clerkenwell, London.

15826. **Improvements in the insulation of electric cables.** George Gatton Melhuish Hardingham, 191, Fleet-street, London. (The firm of Felten and Guilleaume, Germany.)

15827. **An improved arrangement of apparatus for the generation of electricity on railway carriages or trains for lighting or other purposes.** Basil Rebikoff, 47, Lincoln's-inn-fields, London.

AUGUST 23.

15863. **Improvements in dynamo-electric or electro-dynamic machines.** John Grice Statter, 68, Victoria-street, Westminster.

15868. **Improvements in arc lamps.** Joseph Devonport Finney Andrews, 45, Fulham Park-gardens, London.

15870. **Improvements in and relating to electrically-controlled weighing-apparatus.** Lorenzo Howard Nutting, 77, Chancery-lane, London. (Complete specification.)

15880. **Improvements in electric accumulators.** Ernst Waldemar Jungner, 18, Buckingham-street, Strand, London.

15886. **Improvements in or connected with electric batteries.** Charlton James Wollaston, 4, South-street, Finsbury, London. (Complete specification.)

15889. **Improvements in the construction and working of electric arc lamps.** La Société les Fils d'Adolphe Mougin, 191, Fleet-street, London. [Date applied for under Patents, etc., Act, 1883, Sec. 103, 11th February, 1895, being date of application in France.]

15895. **Improvements in electric contact making and breaking apparatus.** Samuel Quincey and John Hoar Collins, 46, Lincoln's-inn-fields, London.

AUGUST 24.

15899. **Improvements in the construction of telephone instruments.** Thomas Frederick John Truss, 6, Pickering-road, New Brighton, Cheshire.

15952. **Improvements in or appertaining to electric lighting apparatus.** William Phillips Thompson, 6, Lord-street, Liverpool. (Wilhelm Kaiser, Austria.)

15969. **Improvements in incandescent lamps.** Peter Stiens, 24, Southampton-buildings, Chancery-lane, London.

SPECIFICATIONS PUBLISHED.

1894.

8607. **Electrical exchanges.** Thompson. (Keith.)

15004. **Telephonic installations.** Ritter.

17130. **Electrically heating liquids.** Stotz and Schindler-Jenny.

17774. **Electrical signalling apparatus.** Phonophore Company, Limited, and Smith.

18661. **Electric fuseholder.** Acme and Immisch Electric Works, Limited, and Moy.

18662. **Electric switches.** Acme and Immisch Electric Works, Limited, and Moy.

1895.

7458. **Electrolysis of metallic salts.** Kellner.

10445. **Electrolysis of alkali salts.** Störmer.

12161. **Electric conductors.** Moulart.

12468. **Electric railways** Müller.

NOTES.

"**Harnessing Niagara**" is the title of an article in the current number of *Blackwood* by Prof. G. Forbes.

The Telegraph in South Africa.—Palapye and Belingwe and district are to be connected by telegraph with Buluwayo. Telegraphic communication between Umtali and Fontesvilla was established on July 21.

Books, etc., Received.—"The Universal Directory of Railway Officials, 1895," the Directory Publishing Company, of 8, Catherine-street, W.C. (10s); "Railway Wall Map of England and Wales," W. and A. K. Johnston, White Hart-street, E.C.

Proposed Paris and Rome Telephone.—The French Government, a Dalziel telegram says, is again opening negotiations with the Italian Government for the establishment of telephonic communication between Paris and Rome, *vid* Milan and Florence.

The Telephone in the House.—Telephonic communication between the Colonial Office and the House of Commons has been for some time in existence, but an instrument has now been placed in the Secretary of State's department, so that Mr. Chamberlain and his secretaries can at any time communicate with each other.

The Electric Light in India.—Calcutta has at last, a correspondent says, had the way made clear for the introduction of electricity for lighting and other purposes, for the legislative Act, which has been before the public for some months past, has now become law, and it is open to enterprising persons to put forward their projects.

The Stock Exchange and the Electric Light.—The *Financial Times* remarks that the settlement just completed has been quite as heavy as any that have gone before, the City being quite brilliantly illuminated all Wednesday night. The gas and electric lighting companies, the paper adds, must have reaped a rich harvest in the City this year.

Electric Cranes at Dover.—The Dover Harbour Board have decided to further improve the arrangements for landing and embarking at the Admiralty Pier by the construction of electrical cranes for the transference of passengers' luggage between vessels and trains. This, it is said, will often save 20 minutes or more in the despatch of the mail steamers.

Darkness!—Who will credit it at the end of the nineteenth century? A largely-attended meeting of the inhabitants of Clewer Without, almost at the gates of Windsor Castle, has refused to adopt the Lighting Act, and the parish is consequently to remain in darkness. A wag suggests that this "black spot on the Thames" should henceforward be known as Clewer-without-light.

An Important Telephone Suit.—Papers have been served on the National Telephone Manufacturing Company, at Boston, on behalf of the American Bell Telephone Company, of Boston, in a suit for an order restraining the latter firm from infringing the Berliner patent. It is said that the case will test the validity of the Berliner patent, and will be fought by the National Company with the assistance of several other telephone corporations.

Electricity in South America.—A correspondent writes that the telephone lines to La Plata have reached such a state of deterioration that conversation between Buenos Ayres and La Plata is virtually impossible; and that the proposed metropolitan railway for Monte Video is being strongly opposed in the Chambers, on the ground that the "viaducts, after the manner of the New York Elevated Railroad, would be very prejudicial to the inhabitants of the neighbourhoods which they crossed."

Light Comparisons.—The well-known German Prof. Wedding ranks the different methods of lighting in the following order, considering only the cost: incandescent gaslight, incandescent alcohol light, petroleum, Argand burner, electric incandescent light, and acetylene. He adds that the arc light is ahead of all the others, that the cost is the same as that of the incandescent gaslight, and that it is decidedly the best light for outdoor purposes.

Electric Headlights.—Electric lights will soon succeed oil-lamps as headlights on all the passenger-train locomotives of the Southern Pacific Company. This company has been experimenting with electric headlights for some time, and has at last, it is stated, perfected a light that can be operated by a dynamo on the engine, which will illuminate the track for a distance of 2,000ft. ahead. The Southern Pacific will be the first railway company in the United States to equip all its passenger-train locomotives with electric headlights.

Tunbridge Wells Electrical Exhibition.—An electrical exhibition will be held in Tunbridge Wells early in October, either at the Great Hall or the Town Hall, and there will be a formal switching on of the light by Lady Salomons. It is stated that applications for private lighting are coming in very rapidly and that there are now no fewer than 3,000, and the mains are about to be extended. Some additional arc lamps are, moreover, to be set up in the main thoroughfares, and in future the street-lighting will be continued on Sunday evenings.

The Latest London Railway Scheme.—It is stated that the construction of an overhead railway from Waterloo Station to Cannon-street Station is projected, that all the necessary surveys have been made, and that the Bill authorising the undertaking will be promoted in the next session of Parliament by the South-Eastern Railway Company. The new line would compete with the underground electric system now being built, but we are semi-officially informed that the promoters of the scheme are not very sanguine as to the ultimate consummation of their project.

Electrical Interference.—In the discussion on a paper read before the Chicago Convention of the North-Western Electrical Association, Mr. A. V. Abbott stated that there have been cases of continuous-current lighting in Germany "in which the establishment of a neighbouring alternating current actually put the lamps out—that is to say, interfered to such an extent that the lighting could not be carried on. By the introduction of appropriate impedance coils the trouble was practically cured. The method of transposition accomplishes the same result, but cannot always be employed."

The Anglo-French Telephone Charges.—Replying to Mr. B. L. Cohen, in the House of Commons, Mr. Hanbury has repeated his statement of the 27th ult., that the charge for the use of the London-Paris telephone was the subject of international agreement, and could not be altered without the concurrence of the Government of France. The Postmaster-General did not, he said, at present see his way to propose that the charge for a three minutes' conversation between the hours of 5 p.m. and 11 a.m.—the hours in which the telephone is now least in demand—should be reduced from eight to four shillings.

Light Railways in the Highlands.—In the House of Commons on Monday Mr. Baillie asked whether during the recess her Majesty's Government would enquire into the whole question of promoting a system of light railways on the west coast of the Highlands of Scotland, and would obtain such local information on the subject as would best bring out the particular claims of the various

Digitized by Google

districts of the country for the development of their natural resources. In reply, the Lord Advocate said that the Secretary for Scotland fully recognised the importance of the subject, and intended to look into the matter and to give it his careful consideration.

Electricity v. Gas.—This is the way in which Mr. Wm. Bruce, of Leeds, opens a paper on "Gas Heating, Cooking, and Ventilation": "Gas engineers and manufacturers of gas stoves and cooking ranges have made many important improvements lately, and although gas is now largely used as a motive power, there is undoubtedly the disagreeable prospect before all interested in the manufacture and consumption of gas, from the producers' point of view, that at no distant date some of the large works fitted with the latest improvements may be found capable of supplying more gas than the consumption demands, owing to the progress of electricity for illumination."

The Ipswich Technical College. — The Town Council of Ipswich propose to convert Christchurch Mansion into a technical college, in which classes on the following subjects would be held: machine drawing and construction; applied mechanics; steam, magnetism, and electricity; electric lighting and telegraphy; sound, light, and heat; human physiology; biology; hygiene; principles of agriculture; botany; physiography; typography; manual training in woodwork; wood carving; wood turning; plumbing, painting, and graining; cooking; laundry and dress cutting-out. Commercial subjects: shorthand, book-keeping, geography, arithmetic, Latin, French, German.

The Queen v. Electricity.—The Queen is said to be a very determined opponent of the use of electricity, and to have forbidden its extension in any of the Royal palaces, so far, at any rate, as the apartments frequented by herself are concerned. Indeed, according to the London correspondent of a Manchester paper, she is adverse to the employment of electricity as a motive power for any purpose. The suggestion was recently made that the lifts which have to be erected in every building occupied by her should in some instances be actuated by electricity, and this suggestion was promptly rejected. Any hope, too, that may once have been formed as to the introduction of current for ventilating or for cooking purposes, has now, it is stated, been entirely abandoned by the officials concerned.

The Electric Light in Russia.—The passenger trains on the following Russian railways are to be electrically lighted before the close of the present year: Nikolai, Warsaw, Nishegorod, Rjasan-Ural, Kursk-Charkov-Azov, and Losovo-Sevastopol Railways. The project for the construction of a ship canal between the Baltic and Black Sea has now, it is stated, taken definite shape. The new canal will start from Riga, and following the course of the Duna, the Berezina, and the Dneiper rivers, will terminate at Kherson, on the Black Sea. It will be 1,600 kilometres, or 1,000 miles, in length, will have a depth of nearly 30ft. and a surface width of 200ft., and will measure about 100ft. across at the bottom. It will take five years to construct, and it is estimated to cost 200,000,000 roubles, or £30,000,000. At night the canal will be lighted by electricity, enabling vessels to traverse it in six days at the rate of about seven miles an hour.

Electric Tramways in Belgium.—It is stated that the Compagnie des Tramways Bruxellois has concluded a contract with the Berliner Elektricitäts-Gesellschaft "Union," whereby the latter firm engages to construct and complete within 12 months an electric tramway, five English miles long, from Schaerbeek to the Bois de la Cambre, Brussels, on the underground conduit system, as adopted in Budapest. The proposal of Colonel North to purchase a considerable area of Government ground at Ostend, on which to erect a large hotel and establish winter and pleasure gardens and villas has been favourably decided upon by the Upper House of the Legislature. The purchase also includes the right to work an electric tramway along the sea-front from the pier for a period of 99 years. Work upon the hotel and tramway will, it is said, be begun at once, in order to enable this portion of the undertaking to be completed by the opening of the exhibition in 1897.

The Grumbler Again.—This is a fair specimen of the style of the man who never posts a letter, despatches a telegram, or takes a railway journey without following the example of the famous young Etonian who, his Christmas cake having been somewhat "delayed in transit" by the railway company, ingenuously requested his father to "plese rite to the *Times*" about it:

TELEGRAPHIC ACHIEVEMENT.—Sir,—You have given so much space to recording the achievements in speed of railway companies that I hope in justice to a State department you will find a corner to record the fact that I have just received a telegram bearing the following startling dates: Leicester-square, 5 p.m.; Ludgate-circus, 5.42 p.m. The distance must be nearly two miles, and the telegraphic speed fully three miles an hour. We may scoff at the progress of the nineteenth century, but some of our grandmothers could hardly have walked the distance in less time.—Yours, X.

Some people never stop to think that it is but in consonance with human nature that of the trillions of letters, telegrams, and railway trains despatched in the course of a year one must now and again go wrong.

Machinery Exhibition at Vienna. — We have received the following communication from the Imperial and Royal Austro-Hungarian Consulate-General, 11, Queen Victoria-street, London, E.C.: "Encouraged by the great success of the exhibition of agricultural machinery held at Vienna during May last, the I.R. Agricultural Society in Vienna has decided to hold a second exhibition in May next year. The prospectus will include not only agricultural machines, in the strict sense of the word, but appliances used in all branches of industry connected with agriculture, such as breweries, distilleries, yeast, sugar, vinegar, and starch factories. The mart will also extend to tools and engines used in forestry, saw mills, celluloid factories, orchards, vineyards, in the feeding and breeding of cattle, horses, fish, etc. It will comprise electrical machines in the service of these industries, seeds, and manures. Provisional applications for space (which will not be considered binding) will now be received by the Committee of the Second International Exhibition of Machines, I. Wien, Herrengasse 13, Austria."

Obituary.—We regret to have to announce the death, on August 30, of Mr. H. C. Hart, one of the first-class technical officers of the engineer-in-chief's office, Post Office Telegraphs. Mr. Hart joined the telegraph department in June, 1870, shortly after the transfer of the companies' business to the State. He has throughout his official career taken a keen interest in the great developments of the telegraph and telephone industries and in Post Office work generally. He was a director of several of the mutual associations started and managed by Post Office men for the benefit of their brother officers. His loss will be deeply deplored by all with whom he was brought into contact. The interment took place on Monday, the 2nd inst., at Elmer's End Cemetery. Among those present to render a last tribute of respect to their late colleague were Mr. J. Hookey (assistant engineer-in-chief), Messrs. J. B. Chapman, T. H. Stockwell, P. Ennis, J. W. Curra, R. C. Lever-

Digitized by Google

sedge, T. Reid, and J. Ward (of the engineer-in-chief's office), and many representatives of other branches of the Post Office. The deceased gentleman was 49 years of age.

Light Railways in Essex.—The proposed opening up of the remote parts of Essex by means of light railways is assuming a practical shape, and is deserving of sympathetic encouragement. The Hon. Charles Strutt, the member for the Maldon division, showed his interest in the scheme by presiding over the conference of landowners, farmers, and manufacturers at Tiptree Heath which considered the matter, and that meeting approved the idea of a light railway from Kelvedon to Tollesbury, on the Essex coast. It was stated that the line could be constructed for some £1,500 per mile, including purchase of the land, and a deputation to wait on the Great Eastern Railway Company, to ask their assistance, was appointed. At the figure mentioned, a light railway through an agricultural district at present destitute of all facilities for locomotive traffic ought to be a commercial success, but if it is to serve as a feeder to the existing railway, it must, even though the permanent way is less solidly built, be of the same gauge, for to reload the traffic when it reached the Great Eastern line would be to destroy much of the advantage of the proposed new railway.

Personal.—On Tuesday last a farewell banquet was given by the works staff of Messrs. Siemens and Co., in the Holborn Restaurant, to wish success to Mr. E. Weegmann in his new sphere in Germany. Mr. Weegmann has been connected with the above-named firm for 14 years, and has for a number of years had the control of the construction of the dynamos, alternators, etc. He has in this capacity gained the esteem of his colleagues by his uniform courtesy. A large number of the staff were present, under the chairmanship of Mr. F. Hurd, who, after the loyal toasts had been duly honoured, referred in a well-worded speech to the regret they felt at losing Mr. Weegmann. He had for years shown great kindness and consideration to those with whom he came in contact in the works, and had smoothed the little inter-department trouble by his geniality. In proposing the health of their departing friend he would wish him, in the name of all present, great success in his new work. Mr. Weegmann, who is leaving England to take up an important Government post in Germany, in reply said that he was proud to have made so many good friends in England, and that he should always remember his fellow-workers at Siemens and Co. with pleasure.

Chinese Telegraphy. — Telegraphy, Dr. G. E. Morrison says, has reached a stage of development in Yunnan which portends well for the future of the Indo-(or more correctly Burmah) China overland wire. The Chinese telegraph code is simplicity itself. The code-book consists of 10,000 numbers of four numerals each, and each group so constituted represents a Chinese character. Any operator, however ignorant, can thus receive or telegraph a message in Chinese, and the Chinaman's memory is so prodigious that he rapidly learns all the essential parts of the code-book by heart. The system, moreover, permits of the easy arrangement of undecipherable private codes, which are extensively used, since, by adding or subtracting a certain number from each group of figures, other characters than those telegraphed can be indicated. It is claimed for Chiang, the second Chinese clerk in Yunnan, that he knows all the 10,000 numbers and their corresponding characters by heart. The telegraph is very largely used by the Chinese, especially by bankers, in making telegraphic remittances. Telegrams from Yunnan to Shanghai cost the equivalent of 6d. for each Chinese character, but each word in any other language is charged double.

An Electric Snowstorm is the very latest Yankee discovery. Lieutenant John P. Finley, "one of the best-informed meteorologists in the country" encountered it while making an ascent of Pike's Peak. He says the storm could be described "as a shower of cold fire. In reality it was so charged with electricity as to present a scene more easily imagined than described. At first the flakes only discharged their tiny lights on coming in contact with the hair of the mule on which the lieutenant was mounted. Presently they became thicker and faster, each flake emitting its spark as it sank into drifts of the snow, or settled on the clothing of the lieutenant or the hair of the mule. As the storm increased in fury and the flakes became smaller, each of the icy particles appeared as a trailing blaze of ghostly white light, and the noise produced by the constant electric explosions conveyed an impression of Nature's power which Lieutenant Finley will never forget. When the storm was at its height and each flake of snow was like a drop of fire, electric sparks were shaken in streams from the lieutenant's finger tips, as well as from his ears, beard, and nose, and a wave of his arms was like the sweep of flaming sword-blades through the air, every point of snow touched giving out its little snap and flash of light."

Our First and Only Electric Mountain Railway, the Snaefell line, is meeting with such conspicuous success that extensions are already being talked of. A Douglas correspondent writes: It is not probable that this undertaking will end at the top of Snaefell. Already there are rumours of a scheme for continuing the line through Sulby Glen, and connecting it with the railway system between Douglas and Ramsey. The distance to be traversed by the connecting line need only be about four miles; the gradient is an easy one, and the cost much less per mile than that of the line which has just been completed. At the head of Sulby Glen are grounds which are already resorted to by thousands of visitors during the summer, and as the suggested connecting line will pass through these grounds, the promoters will have a certain amount of assurance as to the financial result of the scheme. One of the great advantages of this new line will be that by means of the electric system between Douglas and Snaefell, and the connecting line through Sulby Glen to the Manx Northern Railway, visitors would be able to make a circular tour, returning to Douglas by train, which will reveal to them the chief features of Manx scenery in mountain and glen. There is little doubt that some scheme of this description will be carried out, though whether the Snaefell Tramway Company or the existing railway companies will take the matter up, is not yet known. The latter are viewing with some concern the effect of the operations of the electric tramways upon their traffic, and it will probably lead them to take steps somewhat on the lines indicated.

The Westinghouse-Baldwin Combination.—From details which are published of the recent arrangement between the Westinghouse Electric and Manufacturing Company and the Baldwin Locomotive Works, of Philadelphia, it appears that the union is not the close one which has been represented, and that it merely amounts to a business agreement whereby the Westinghouse and Baldwin companies will each manufacture the parts of electric locomotives and high-power cars for which, by shop equipment and experience, the one or the other is the better fitted The former company will, of course, supply the electrical equipment and the other the remaining part of the rolling-stock. This is a natural arrangement, and similar in some respects to that which has existed for some time between the General Electric Company and the Schenectady Loco-

Digitized by Google

motive Works. At the Baldwin Works draughtsmen are busily working upon plans for the new type of electric locomotives which the Baldwin-Westinghouse combination intends to produce, and an engine after the new design will, it is stated, be ready for inspection in about a fortnight. Two trucks will be made—one for light work and elevated roads, the other for the heavier class of suburban traffic, suitable for hauling 12 or 15 cars. These trucks can, we are told, by fitting them with motors of different power, "be made to serve all the requirements of electric roads, from the lightest elevated, with a maximum speed of 40 miles an hour, to the fastest suburban work of 90 miles an hour." It may be noted, by the way, that the construction of the Washington and Alexandria, Virginia, Electric Railway has been commenced, for which the trolley will be used outside the city and the underground conduit inside, while in crossing the Potomac the tracks of the Pennsylvania Railroad will be utilised; and that the Johnson Steelworks at Loraine, Ohio, have been awarded a contract for 30,000 tons of steel rails for the electric road between Washington and Baltimore.

Electricity v. Steam.—A writer in *Herapath's Railway Journal* discusses this subject. The directors of the Metropolitan Railway at the present time, and indeed the British railway world in general, must, he says, have their thoughts turned afresh to the possibility of utilising electricity as a tractive force for railway purposes. Hitherto, with the exception of a few tramway lines, the little railway at Portrush, and the new mountain line in the Isle of Man, electric traction has mainly been confined to the City and South London Railway and the Liverpool Overhead Railway. In the United States, on the other hand, electricity has been much more largely utilised. For street railways it is coming into general use, and the question is being actively discussed in railway circles whether it should not displace steam on the large trunk lines. A few weeks ago, when the arrangement between the Westinghouse Electric Company and the Baldwin Locomotive Works was announced, it was deemed probable that it would herald a new departure, and this view is largely shared across the Atlantic. Already a good many branch lines of ordinary railway utilise the new force, and the threat is held out that it will be possible to parallel the larger railways with electric lines, which can be worked cheaper for certain classes of traffic. The New Haven road is equipping its Nantasket beach line electrically, the Pennsylvania Railroad is introducing electricity on its Mount Holly branch, and the Baltimore and Ohio is using electric locomotives in its Belt Line tunnel, whilst experiments are under way at Chicago and other points in the like direction. Dr. Louis Duncan, president of the American Institute of Electrical Engineers, is of opinion that if the trunk lines do not recognise and absorb the new rival the latter will absorb them; at any rate, will dissipate the narrow margin which now remains over and above after meeting fixed charges. Electricity he considers peculiarly well adapted for trains running at short intervals and at high speed, and this would answer most of the requirements of passenger traffic. For goods traffic he does not consider electricity in its present stage suitable, because of the irregular service and the unequal distribution of the load along the line. In order to maintain dividends, he says, most of the two-track roads will either have to build additional electric lines or else control those that he feels sure will parallel them.

Electric Clocks.—The idea of applying electricity to timekeeping is by no means new, but the system, after a long spell of comparative quiet, has recently come to the front with a bound. The British Government has lately had the whole of the outdoor departments at Woolwich Arsenal fitted with these clocks, and they are in use, in London, at the South-Western District Post Office, as well as at the Mint, the telegraph works at Mount-pleasant, the Hugh Myddelton Board Schools, the Army and Navy Stores, Liverpool-street Station, and in other public buildings of the Metropolis. Owing to the great care which has been taken in the insulation of the wires conveying the electric current and in placing them secure from contact with all telephone, telegraphic, and electric lighting wires, not a single deviation in the matter of correct timekeeping has, it is stated, been observed in all these clocks during the recent severe thunderstorms in London. Amongst the private residences where electric clocks are in successful working is Blagdon, Sir Matthew White Ridley's seat in Northumberland, where the present Home Secretary, who takes the greatest possible interest in electricity, has such appliances fitted up for every conceivable purpose. In Great Britain, the city of Glasgow apparently first led the way in the use of the new timepieces. The Council of that city, having decided to place synchronised clocks at the corners of all the principal streets of the city, took steps to discover the best means of accomplishing its object, and after a careful trial of several systems under the superintendence of Prof. Becker, of Glasgow Observatory, it was decided to tentatively adopt the system of the Standard Electrical Time Recording Company, of Belgium, and the work of preparing and constructing the trial installation was entrusted to Messrs. J. J. Stockall and Sons, of Clerkenwell. First of all there is a main clock, which makes an electrical contact every half-minute, and transmits the current to as many receiver-dials as may be connected with it, thus causing the hands of all the dials to move automatically each half-minute. To ensure the accurate timekeeping of the main clock it is fitted with a Ritchie pendulum, which receives a current of electricity from the observatory clock every second. The pendulum thus controlled is absolutely compelled to keep time with the observatory clock. In connection with the system an elaborate switchboard has been arranged, which will be placed in circuit with the town clocks. By its means a break or interruption can at any time be detected, and the locality of the damage determined.

The Effects of Lightning.—The correspondence on this subject which is taking place in the *Times* has produced one or two letters of tolerable interest. Mr. G. J. Symons writes: "The bifurcation and ramification of lightning are so frequent that they may almost be regarded as its general characteristic. I am sure that I have more photographs of divergent than of single-track lightning. As regards double injury by one flash I can (without searching) quote three instances: (1) a corner house in Camden-square, N.W., struck at two points 25ft. apart; (2) two oaks in Richmond Park, many feet apart, were struck, one being damaged much more than the other; (3) the following is the verbatim report, dated January 18, 1889, of my late friend, Mr. James Sidebottom, of Millbrook, Hadfield, Manchester: 'There was one immense discharge, a few years back, right over my brother's cotton mills, a huge ball of fire bursting into fragments and striking some dozen different points, one being the flagstaff of a Roman Catholic church about a quarter of a mile distant.'" Sir Charles S. King, Bt., of Fermanagh, reprints a quaint tale: "The Rev. Dr. William Henry, F.R.S., a very close and careful observer, describes in his 'Description of Upper Lough Erne in 1729' (published 1892), the accident to Belturbet Castle, the seat then of Viscount Lanesborough, by this globular lightning, which seems worth quoting: 'About 20 years ago (1719) this

Digitized by Google

castle was struck in an extraordinary manner with lightning, the traces of which are preserved to this day, and seem to confirm the philosophical opinion that what the vulgar call the thunderbolt is only the focus of that stream of liquid fire which is then discharged. This thunder struck the top of the castle close by the stack of chimneys, from which it shot down perpendicular to the bottom. The hole it made in the garret ceiling through which it darted is scarce 3in. diameter. This seems to be the very focus; from thence diffusing it knocked to pieces the stone of the hearth, and cut to itself a circular passage about 3ft. diameter; descending to the next floor, and growing more diffused, it cut through the hearth and floor a passage of about 8ft. diameter; from thence descending into the hall, and spreading wide, it, by the violent concussion of the air, dashed down two stands of arms hung round the hall, and broke out of the door, tearing down one side of it. Two women were in the hall—the one who stood on the further side, near the arms, was struck down, astonished but not hurt; the other, who was that instant shutting the door, was struck half dead; that side of her next the lightning was left all black, the other not in the least discoloured; she in a few days recovered and attended me at the time I observed this progress of the thunder.'" Another correspondent adds his evidence to an instance of lightning striking a plurality of trees at the same time. He was trout-fishing many years ago near the top of a mountain in America, when a heavy thunderstorm came on. He sought shelter under a large projecting rock; a "heavy explosion of electricity partially stunned" him. After the storm had passed he found that the lightning had struck seven chestnut trees within a radius of about 100 yards, all about 12in. in diameter, very tall, and all on the same side as that from which the storm was approaching.

The Telephone Newspaper.—A Vienna correspondent, who recently visited Budapest, furnishes some particulars concerning the *Telephone Hirmondo*, or *Herald*, which has now been working, apparently successfully, for over two years in the Hungarian capital, although when its conception was first mooted the idea encountered considerable ridicule. "While I was dressing in the morning," the correspondent relates, "the hotel servant knocked at my door and asked if I wanted the telephone paper. He then handed me two receivers about the size of a pocket watch, attached to long cords, which can be fastened to the bed or arm-chair to suit one's convenience. 'The newspaper will begin to speak directly,' remarked the servant, 'and will go on speaking till late in the evening. We don't charge our visitors anything for it, as it only costs us a penny a day.' Though only lately introduced, the telephone newspaper has become almost indispensable; it is to be found everywhere in this capital, and not only in places where persons require amusement or distraction, as in doctors' waiting-rooms, at barbers' shops, coffee-houses, restaurants, and shops of all kinds, but also in the offices of merchants, bankers, and lawyers, in hospitals and private houses, for the use of aged people to whom reading is fatiguing. It speaks all day, but does not give the news in a chaotic jumble, but minute by minute. It is imparted in strict accordance with the programme received by each subscriber. In this way each person knows when the turn will come for the news interesting to him. It was half-past eight when I put the receivers to my ears, and the day's work commenced for the newspaper. It began by transmitting the telegrams received in the night from Europe and America in a clear sonorous tone, quite free from the nasal twang of the ordinary telephone. This went on till a quarter to nine, after which followed the daily calendar with metropolitan news, and the list of strangers who had arrived at Budapest up to the previous night. At nine, official news, contents of the official gazette, etc., were given. From a quarter to ten until a quarter past ten came a review of the Vienna and Budapest morning papers; from a quarter-past ten to half-past ten reports on the opening of the stock and corn exchanges; from half-past ten to eleven local and ecclesiastical news, with theatricals, art and science notices. A quarter-past eleven to half-past eleven brought foreign, provincial, and sporting information; and from half-past eleven to a quarter to twelve reports arrived from the Vienna stock and corn exchanges, with all sorts of military, court, and political items. Early in the afternoon, when the sitting of the Reichstag begins, the parliamentary report is supplied every 10 minutes. The office is in telephonic communication with the Reichstag, and it often happens that important speeches from Ministers and members are known to the public while the speaker is still addressing the House. In this orderly way the programme is carried out until late in the evening. The latest reports from the stock exchanges, as well as foreign political news, are heard before any paper has printed them, and a short summary of all important items is given at noon, and again in the evening, for those who may have missed any of them. Music, art, and literature play important parts in this telephonic organ. Towards evening, when news is growing scarce, the subscribers are entertained with vocal and instrumental concerts, quartettes, and solos—the latter given by the most talented artists of the capital. The National Theatre is now within the circuit of the journal. The telephone newspaper abhors politics; it gives no leaders, only strictly chronicling in an impartial manner the opinions of other papers. It gives, however, original literary articles or feuilletons, and the latter, when written by some such favourite author as Maurus Jokai or Victor Rakosy, are frequently spoken into the telephone by the authors themselves, either from the editorial office or from their own desk telephone at home, placed for the purpose in communication with the office. This novel kind of lecture is heartily appreciated by the feminine public. All these benefits are showered upon the public for 1d. a day! Both wire and apparatus are conveyed free of expense to the subscriber's house. He is only under the obligation to subscribe for one year. The company started with a capital of 300,000fl., and have thus far invested 500,000fl. in the concern. The organisation of the staff resembles that of any other big paper. Ten men with strong voices and clear articulation act as speakers, and take their turns in shifts of two at a time. One of these speaks a series of items, but for no longer than eight or ten minutes, and every new item is introduced by the word 'new.' An emergency signal has lately been contrived by M. Szvetic, the head of the technical department. A shrill trumpet-like blast, audible in the whole room without connection with the receivers, sounds from both of them, warning the subscriber, if he be not at the time listening to the news, that an important event is about to be read. The 6,000 subscribers are served by one wire, measuring 168 miles in length, and running along the windows of the subscribers. Each subscriber forms a 'station.'" The founder of the *Telephone Hirmondo*, Theodor Albert Puskas, was a native of Transylvania and a friend of Edison. He had, it appears, an adventurous career. He at one time obtained from the municipal authorities of Antwerp an authorisation for the establishment of a telegraphic newspaper to be issued on the same basis as the later-conceived telephonic journal. He started the *Hirmondo* on February 15, 1893, and he died on March 16 of the same year at the age of 49.

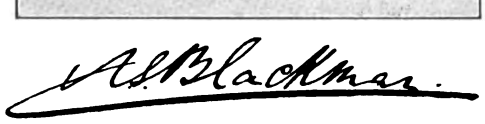
ABERDEEN ELECTRICITY WORKS.

Aberdeen has been brought very much under the public notice lately, it being the goal of the great race between the East and West Coast Railway Companies; the speeds attained in which have not only astonished the British public, but regained for the British Isles the honour of holding the record for fast-running expresses. The "Granite City" is situate between the valleys of the Dee and Don, and covers an area of 10½ square miles, the largest area of any town in Scotland. In 1871 it had a population of only 88,181, but owing to the great facilities for shipping and its splendid railway connections, its importance has so increased that it has now a population of 140,000. William the Lion gave the city a charter in 1129, and Cosmo Jones states that long before Edinburgh had acquired the precedency of a capital, or even the first place among the four burghs of Scotland, while Glasgow was yet an insignificant dependency on its bishop, Aberdeen had taken its place as a great and independent Royal burgh and a port of extensive foreign trade. Robert the Bruce gave the town its motto of "Bon accord," which was the watch-word when in 1300 the citizens stormed the castle, driving out the English garrison placed there by Edward I.



The Municipal Buildings, which are situated in Union-street, are a fine example of Franco-Scottish-Gothic architecture, the tower being 204ft. high, erected In 1867-73.

It is worth noting, in passing, that many of our illustrious shipbuilders and engineers have hailed from Aberdeen, amongst whom may be specially mentioned the late Dr. Charles Mitchell, of the great firm of Sir William Armstrong, Mitchell, and Co., Elswick, who spent large sums of money in promoting the cause of education in his native town and in extending the famous university of Aberdeen, which is the educational centre for the North of Scotland.

The history of the electric lighting movement in this city is briefly as follows: On November 27, 1889, a deputation, consisting of Councillor Cook, the gas treasurer (Mr. P. M. Cran), and the gas superintendent (Mr. Alex. Smith) sent in a report to the Town Council, which stated that they had visited the works of the London Electric Supply Company, St. James's and Pall Mall Supply Company, House-to-House Supply Company, Liverpool Electric Supply Company, and the Bradford Corporation, the result of which visits was that the Council decided to apply for a provisional order. On January 22, 1890, the Gas Committee decided to oppose the application of the Scottish House-to-House Company for a provisional order to supply electricity in the city, and on March 26, 1890, received intimation that the application was not to be proceeded with. The Electric Installation and Maintenance Company also proposed to undertake the construction of the necessary plant and to maintain the work for a fixed period on certain terms, which proposal was not favourably received by the Council. The Gas Committee on February 16, 1892, appointed a sub-committee, consisting of Bailie McKenzie (convener), Bailie Nicol, Councillors Bisset and Johnston, to obtain and submit information in regard to the systems of electric lighting in towns where it had been introduced. They visited the following stations: Bradford, Liverpool, Brighton, Dublin, and Newcastle; and upon their return recommended that Prof. A. B. W. Kennedy, of Westminster, should be requested to visit Aberdeen and report to the Town Council as to the best mode of dealing with the question. Prof. Kennedy, after visiting the town, advised the adoption of the three-wire low-tension system, with a supply at 110 and 220 volts, the estimated cost of the whole of the station—buildings, boilers, engine-room plant, switchboard, batteries, and mains—being £24,400. He also advised that the central station should be built on ground adjacent to the gasworks, and already owned by the Corporation, and thus enable the two undertakings to work together as much as possible. The committee adopted Prof. Kennedy's report, and in response to specifications issued by him the following tenders were accepted:

Station Buildings.

Mr. Robert Smith, Aberdeen, mason's work	£1,744	0	0
Messrs. Scott and Sellar, Aberdeen, concrete work	505	18	0
Messrs. W. McKinnon and Co., Aberdeen, ironwork	410	0	0
Messrs. Watson and Robb, Aberdeen, carpenter's work	351	0	0
Mr. W. W. Milne, Aberdeen, slater's work	95	0	0
Messrs. J. Blackie and Son, Aberdeen, plumber's work	77	0	0
Messrs. J. and S. Fyfe, Aberdeen, painter and glazier's work	63	0	0

A total of £3,245. 18s.

For Plant.

Messrs. Babcock and Wilcox, Limited, London, boilers	£1,494	0	0
Electric Construction Corporation, Limited, Wolverhampton, engines, dynamos, pumps, steam and other pipes	5,044	0	0
Messrs. Siemens Bros. and Co., London, switchboard, instruments, and connections	990	0	0
Messrs. Scott and Sellar, Aberdeen, roadwork	2,671	0	0
Electrical Power Storage Company, London, storage batteries	760	0	0
Messrs. T. Bolton and Sons, Staffordshire, copper strip	820	0	0
Callender Bitumen Telegraph and Waterproof Company, Kent, insulated cable	1,532	0	0
British Insulated Wire Company, Prescot, insulated cable	190	0	0
Messrs. Doulton and Co., London, insulators	176	15	8
Messrs. W. McKinnon and Son, Aberdeen, battery stands	56	0	0

A total of £13,733. 15s. 8d.; and for buildings and plant of £16,979. 13s. 8d.

At the Town Council meeting of June 5, 1893, it was decided to appoint an electrical engineer. Sixty-five applications were received, and Mr. Murray, of Larne, co. Antrim, was chosen, and held the position till February, 1895, when he left to take up the duties of electrical engineer to the Corporation of Worcester. Mr. A. S. Blackman, who was assistant at the time, was appointed *pro tem.*, and the economies he effected—chiefly by the substitution of coke for coal in the boilers—gained for him the confidence of the Corporation. When the applications for the post of electrical engineer to the city were considered, Mr. Blackman was elected by an overwhelming majority, only two voting against his appointment. Mr. Blackman was previously assistant to Mr. C. B. Smith, resident engineer to the Hove Electric Lighting Company, Limited, and also was for seven years with Messrs. Crompton and Co., Limited, both at their Chelmsford and London works.

The formal opening of the works took place on Tuesday,

Digitized by Google

February 27, 1894, when Mrs. Stewart, the wife of the Lord Provost, switched on the light from the Town and County Hall. Amongst the speeches made on this occasion, one by Prof. Kennedy on the adoption of proportional rates is most interesting. Prof. Kennedy said that he had no doubt that the electric light would succeed and grow most rapidly; but he should like to say one or two things in particular about the best way to make it grow, and that was to do all they could to get the very biggest load on as soon as they possibly could, because half their whole expenditure was really fixed charges, perfectly independent of whether they supplied 2,000 units a week or 5,000 units a week. They would have to pay these charges even if the station were shut up, and therefore the more work they did the cheaper they could afford to do it. He had not spoken to any of his friends on the committee about it, but if there was any specially large installation that could be had on the Corporation mains it would be advisable for the Corporation in that case to make a special rate. They had power by Act of Parliament to do that. Suppose they were selling 2,000 units, it would cost them so much for wages, so much for coal and oil and stores and capital charges. If they doubled the 2,000 units by any chance, their expenditure would practically increase only 20 per cent., and their output 100 per cent. They could then afford to sell at a less figure, because the additional cost would only be the additional cost of coal, oil, wages, stores, etc. Hence the taking on of the additional 2,000 at 5d. might give them so much profit as to enable them to reduce all round to 6d. Thus the smaller consumers would get the benefit of 1d. per unit because they had given the larger consumers a reduction of 2d. He was not giving them a mere academic opinion, for he had under his immediate direction and control, in companies that he advised, something like 2½ million units, and he therefore did know something about the sales and profits of the electric light, and he believed what he had suggested was really the best method of reducing the price—making low rates all round, and so making the light thoroughly popular in the best sense of the word.

FIG. 1.—The "Town House," Aberdeen.

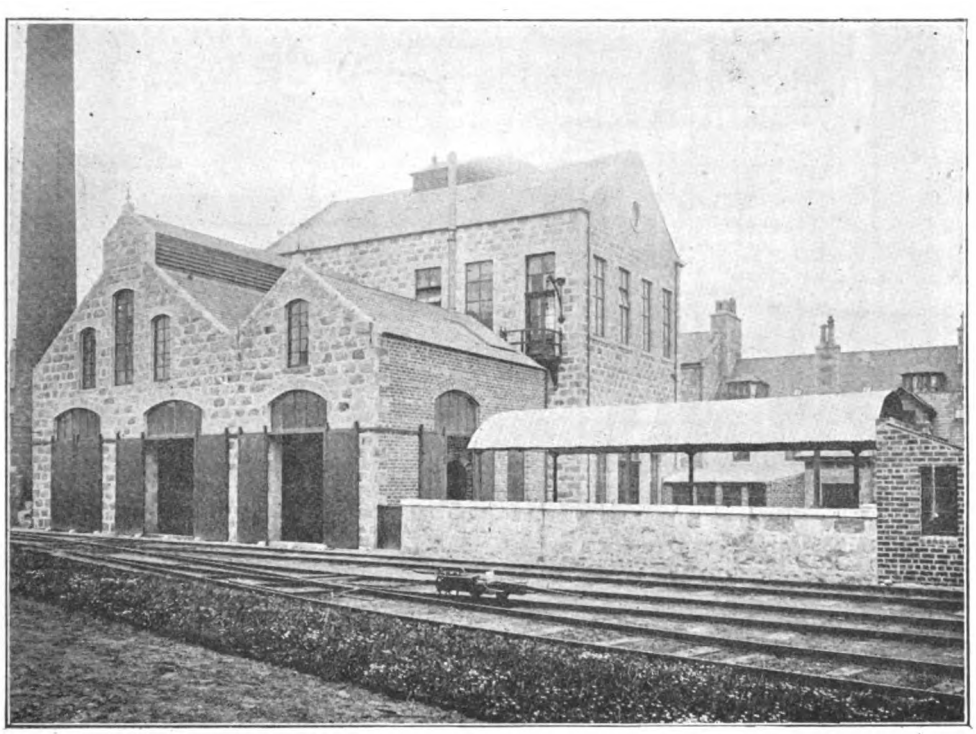


FIG. 2.—View of Electricity Works, Aberdeen, with Boiler-house and Coal-store in Foreground.

Digitized by Google

As will be gathered from the foregoing, the price per unit was first fixed at 7d., but this has been reduced to 6d. for lighting and 4d. for motive power, the price for public lighting being 4½d. per unit. Beyond the reduction for electricity supplied for motive power, the Corporation do not seem to have adopted the reduction to large consumers advocated by Prof. Kennedy. Ten public arc lamps are in regular use, nine in Union-street and one in St. Nicholas-street. The poles used are of the swan-neck type, and are fixed in the kerbs of the footpaths.

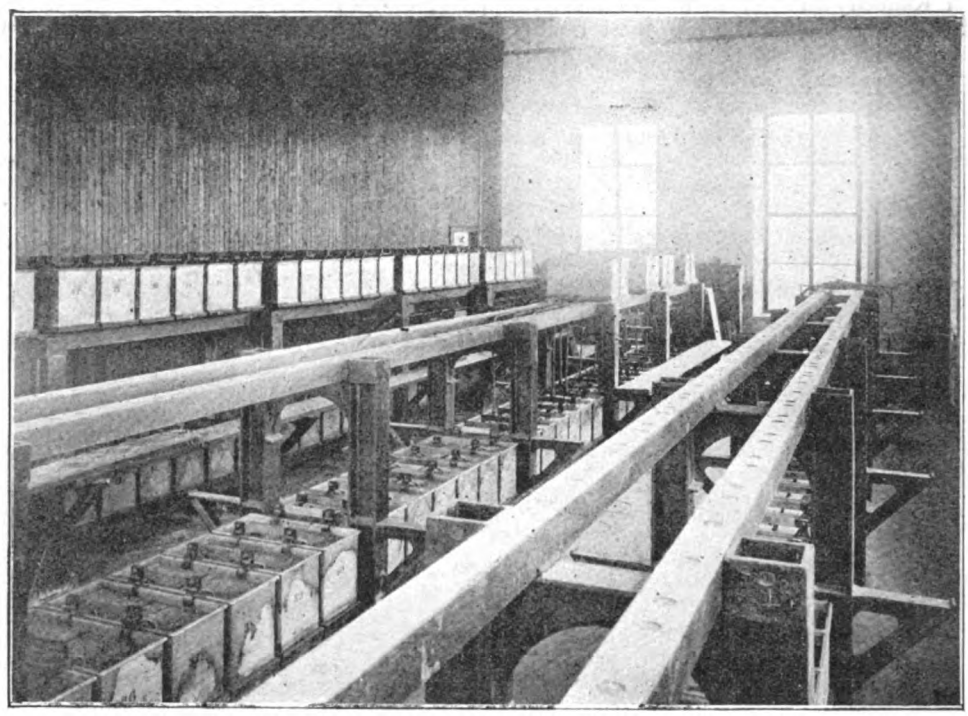

FIG. 3.—The Accumulator-room.

GENERAL DESCRIPTION OF THE WORKS.

The electric lighting station (Fig. 2) is situated on a plot of ground adjacent to the gasworks in Cotton-street, and is a substantial building of granite. On the ground floor are placed the engine-room, boiler-house, and coal-store, and the general offices. A flour-mill formerly occupied the site of the present works, and the old mill chimney has been heightened and utilised temporarily to save initial expense. Foundations are, however, provided for the new shaft at the back of the pump-house. The works are making such

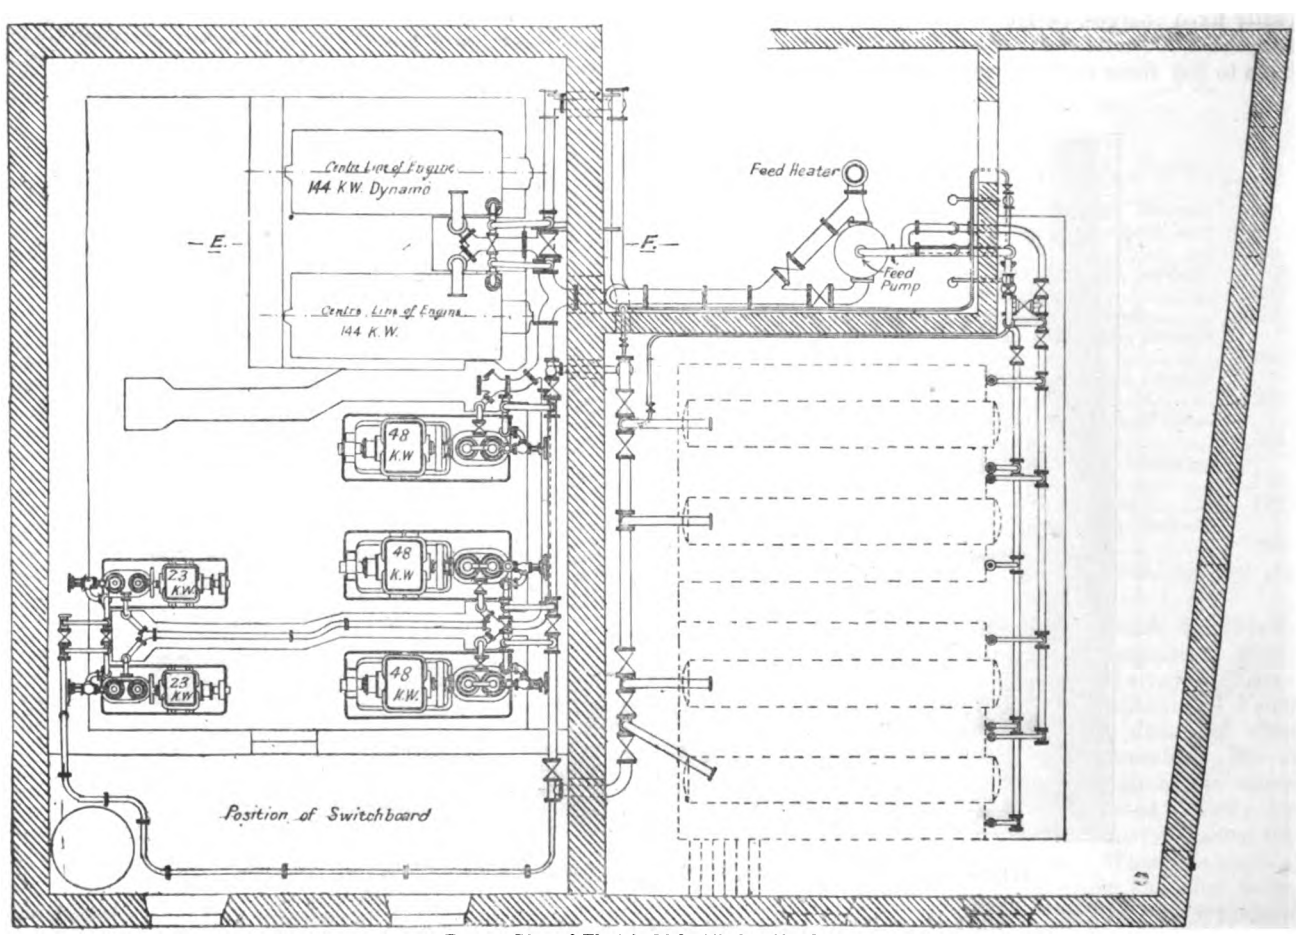

FIG. 4.—Plan of Electric Light Works, Aberdeen.

Digitized by Google

rapid strides that it will, no doubt, soon become necessary to build this new shaft and to extend the engine-room and boiler-house, both of which are now practically filled up. There is, fortunately, plenty of ground available for extensions. On the first floor above the engine-room is situated the accumulator-room (Fig. 3). The floor of this room is built of iron and concrete, to be sufficiently strong to support the weight of the accumulators, and also to be watertight and fireproof. The workshop is on the same floor, and contains the usual vices and workshop appliances. The test-room opens off the battery-room. Upon a long table in the centre are placed the meters to be tested. Leads connected to the milking cells of the battery are brought in to a double-pole cut-out within the room. From there the current passes through a switchboard, provided with regulating resistances, having a capacity of 150 amperes, and also through a standard resistance to the meters.

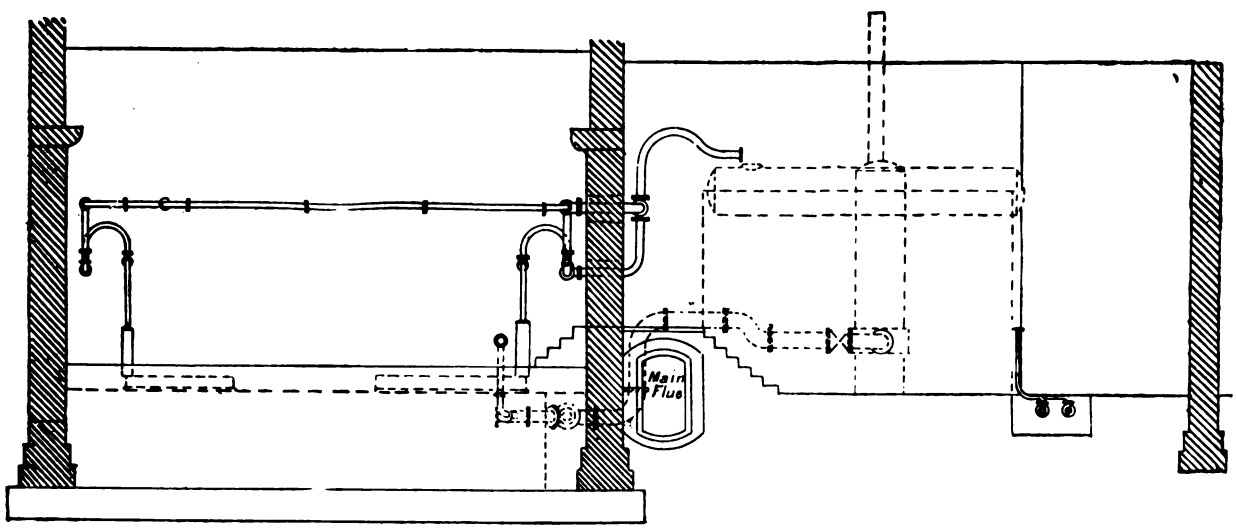

FIG. 5.—Elevation of Station.

GENERAL ARRANGEMENT OF PLANT.

The arrangement of the engine-room will be seen from Fig. 4. The generating plant first installed consisted of the following: two 40-h.p. Willans engines, direct coupled to Electric Construction Corporation dynamos, giving 170 amperes at 135 volts; three 80-h.p. Willans engines, direct-coupled to Electric Construction Corporation dynamos, giving 210 amperes at 230 volts. These were placed at the switchboard end of the room. Since the demand for light has so rapidly increased, there have been added two 200-h.p. Willans engines, direct coupled to Holmes dynamos, giving 500 amperes at 240 volts. It was found necessary to make these additions to the plant after only 10 months' running. A granite cornice running the full length of the engine-room on either side carries the rails of a six-ton ton travelling crane. The walls of the engine-room are tiled to a height of 6ft. A spare armature for each size of dynamo is placed in such a position that it would be at once available in case of emergency. Behind the engine-room are situated the boiler-house and pump-room. The main flue, as will be seen from the elevation, Fig. 5, is placed underground, and so arranged that it can be easily connected to the new shaft when built. The steam-pipes, which are arranged on the ring system, are placed over-

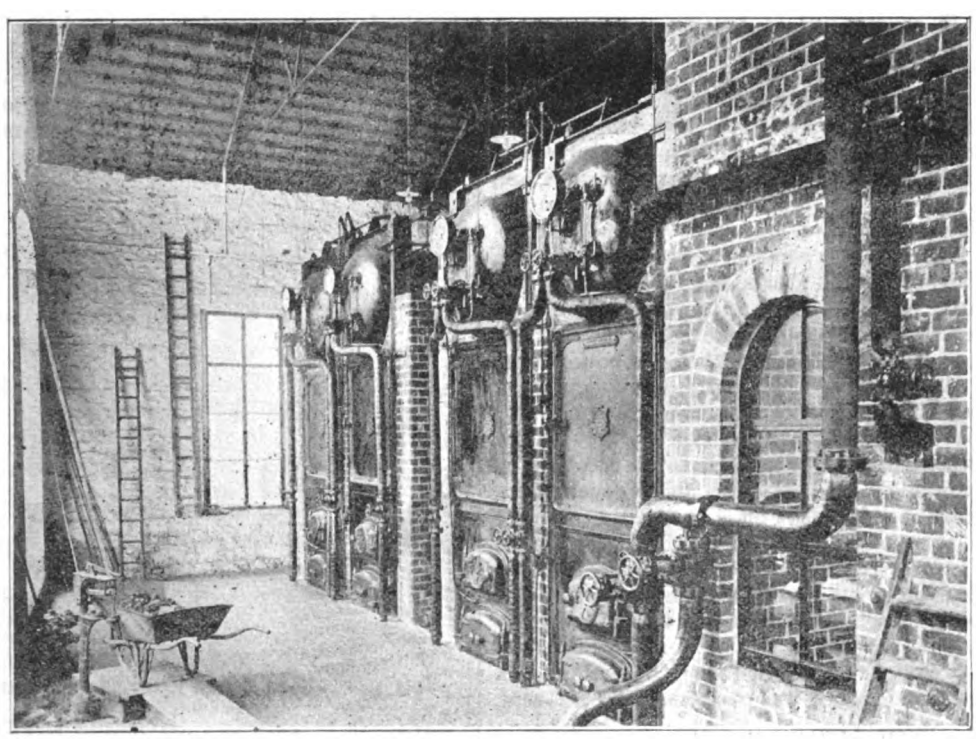

FIG. 6.—The Boiler-house, Aberdeen Electric Light Works.

A Crompton potentiometer is placed on an insulated slab at one end of the room, together with an Ayrton-Mather galvanometer and standard cell. Blinds are fixed to all the windows to enable the spot from the mirror galvanometer to be seen when testing on a bright day. Shelves for the meters, a desk, and Fuller's slide rule complete the equipment. The majority of the meters used are of the Ferranti V.D. type.

Digitized by Google

head, and the exhaust-pipes are arranged in channels in the floors. As no sufficient supply of condensing water is at hand, no condensing plant has been installed.

Steam Generating Plant.

The boiler-room (Fig. 6) is 51ft. by 38ft., and is separated entirely from the engine-room. It contains four 90-h.p. nominal Babcock and Wilcox water-tube boilers, a special

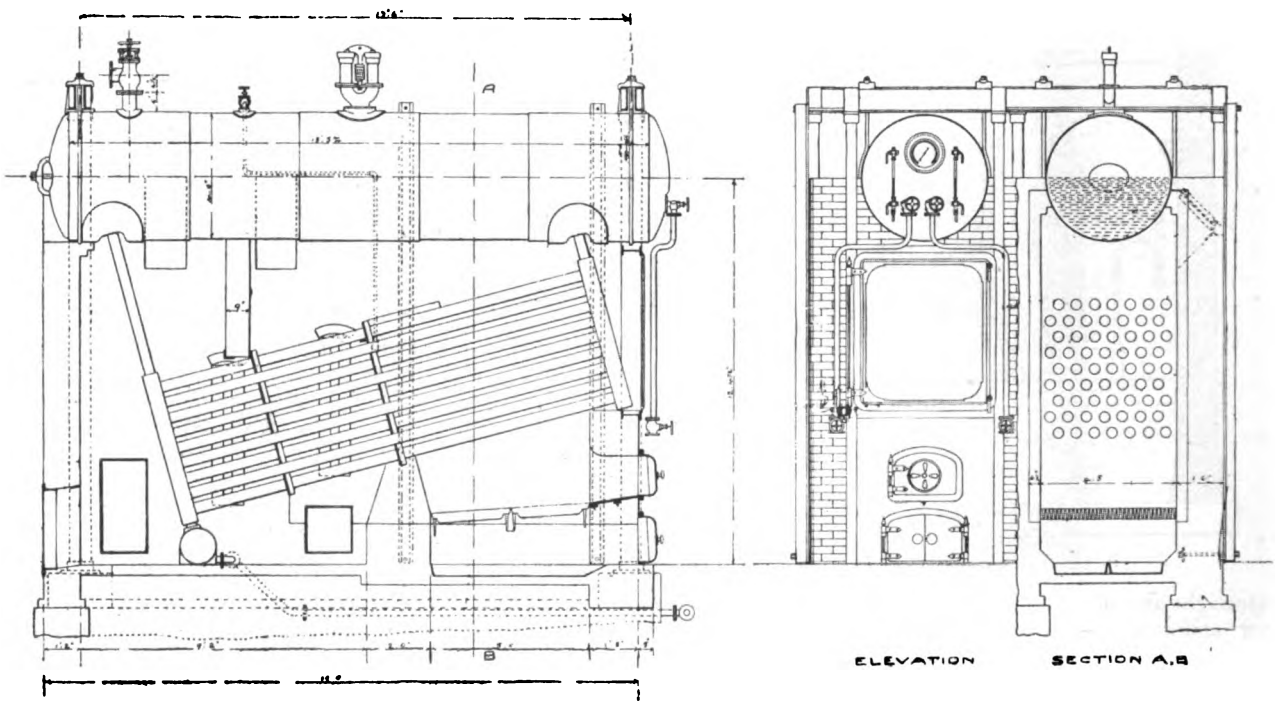

Fig. 7.—Side and End Elevation of the Babcock Willcox 90-h.p. Boilers.

feature of these boilers being the large steam-drums; these are 4ft. in diameter, to comply with Prof. Kennedy's specification. Two boilers are arranged together in one battery, as will be seen from Fig. 7, and each of these boilers has 1,123 square feet of heating surface, and is composed of seven sections of tubes, each section being nine tubes high. The tubes are 4in. diameter and 14ft. long. The steam and water drum is 4ft. in diameter, and the whole boiler is constructed for 160lb. working pressure, and was tested after erection to 250lb. per square inch. Each of the boilers has a duplicate feed arrangement, and has a grate 5ft. long by 4ft. 5in. wide. At first coal was used as fuel in these boilers, but since February, 1895, coke supplied from the Corporation gasworks adjoining has been exclusively utilised; this fuel is found to give most satisfactory results. Owing to the good water available no incrustation troubles have occurred, and Mr. Blackman assured our representative that the boilers were as clean as the day they were erected. A similar boiler has been in use in the adjoining gasworks for some nine years, and the engineer, when written to by Messrs. Babcock and Wilcox in 1893, stated that "it had been in action continually night and day for about seven years, with the exception of a few days off occasionally to repair the sides of the furnace with firebricks, that it had never cost a penny for any repair in connection with the iron work, and had given great satisfaction and had surpassed his highest expectations." He also stated that nothing but the worst quality of coke from cannel coal was used for firing it, and that the saving of fuel over the two Cornish boilers working alongside of it was upwards of 25 per cent.

Feed Arrangements.

There are in the pump-room two feed pumps of the Worthington type, vertical pattern, brass fitted, and suitable for working constantly at a pressure of 160lb. per square inch. Each pump is capable of easily delivering water to the boilers, against the full steam pressure, at the rate of 3,000 gallons per hour, and if pressed is able to deliver 4,500 gallons per hour. The necessary pipes and valves are provided to enable each pump to receive its steam from either of the two main ranges of pipes. These pipes are of copper. The feed-pipes are in duplicate between the pumps, heater, and boilers, and are so arranged that each pump can feed through either range of pipes, through the heater or direct to the boilers. The system of pipes for this purpose is provided with all necessary valves—relief-valves, cocks, etc.—for two pumps, one heater, and four boilers. The relief-valves are arranged to pass all waste water back to the feed-tank. The branches and flanges are so arranged that two more pumps, a second heater, and another line of boilers can be, without difficulty, connected up to the existing plant. The starting valve of the pumps is so placed that the stoker on duty can readily work them from outside the pump-room. All the feed-pipes are of copper, and the feed relief-valves on them are set to lift at a pressure of 180lb. per square inch. One exhaust feed-heater is placed close to the feed pumps. This is of the Berryman type, and was made by Messrs. Joseph Wright and Co., of Tipton. The heater is

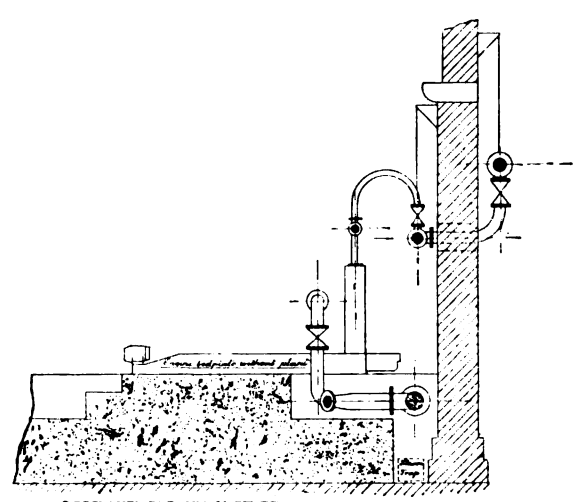

Fig. 8.—Steam and Exhaust Pipe Connections to the 200-h.p. Sets.

constructed to work at a pressure of 150lb. per square inch, and to raise 17,000lb. of feed water from 60deg. F. to about 206deg. F. The heating surface consists of solid-drawn brass tubes. Each tube is bent into the form of a ∩ and expanded at the ends into one tube-plate only, which leaves the tube free to expand in any direction without being strained at the joint. This construction makes leaky joints impossible. The feed-tank is placed below the pump-room in a space excavated to receive it.

Steam and Exhaust Pipes.

The steam-piping is arranged on Prof. Kennedy's ring

Digitized by Google

system, which provides that there are always two ways for supplying any engine with steam. The whole of the pipes are of copper throughout, with faced wrought-iron or steel flanges brazed on. All pipes under 3in. in diameter are of solid-drawn copper. The T-pieces are of cast iron. Every part of the system was tested by hydraulic pressure up to 350lb. per square inch. The whole of the steam-mains in the engine-room are slung by rods from suspending brackets.

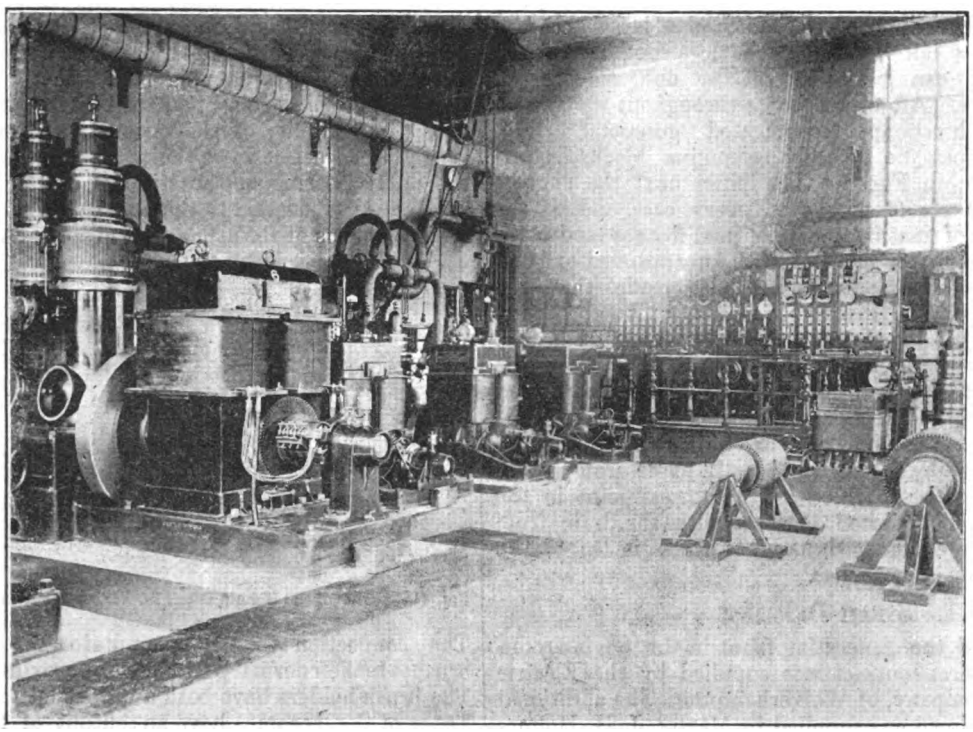

FIG. 9.—View of the Engine-room from the Office Entrance.

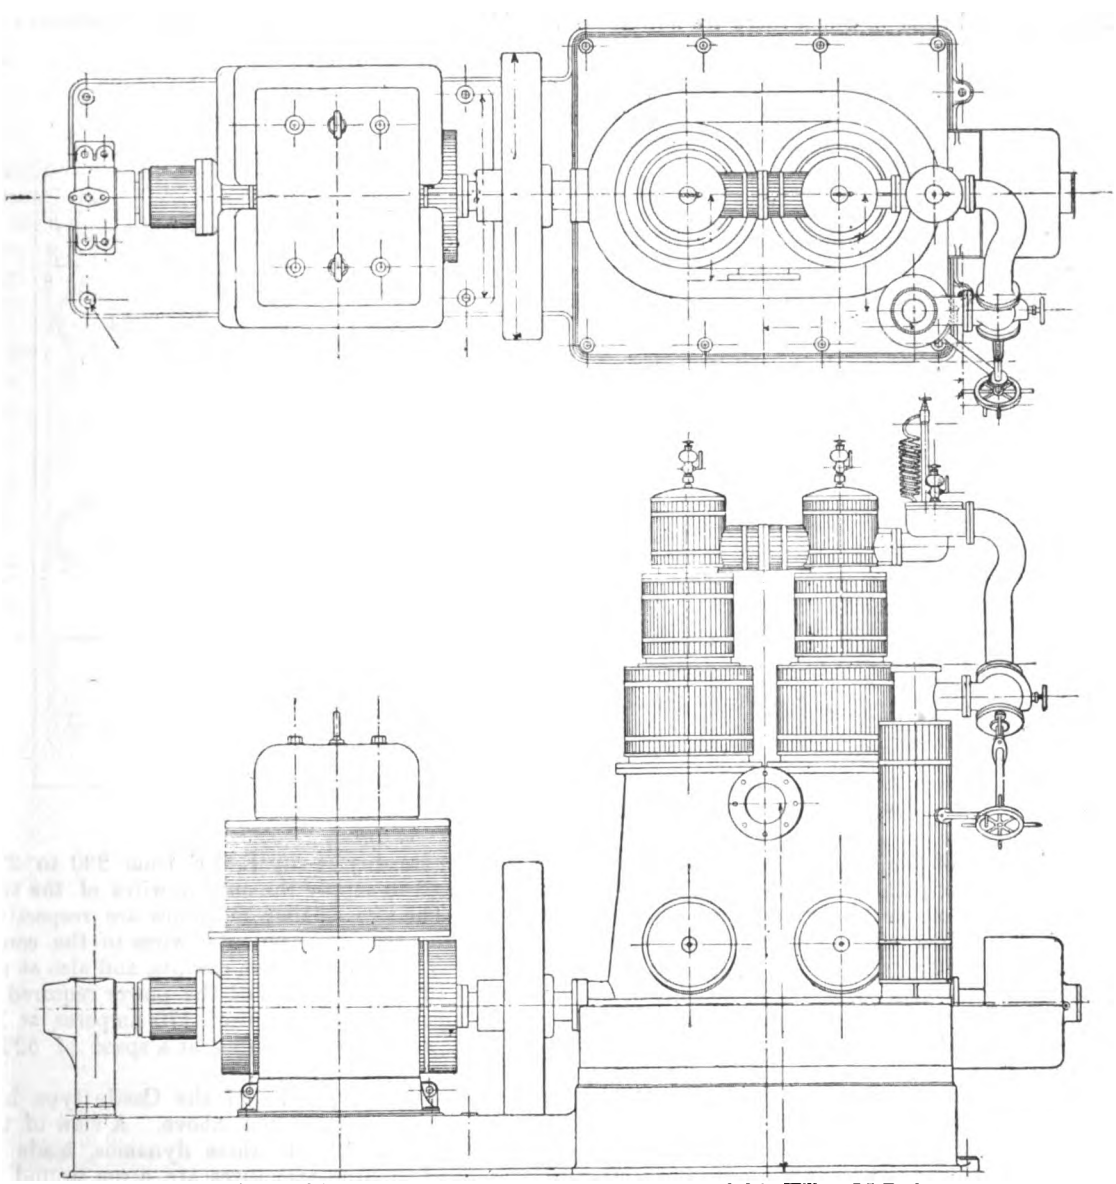

FIG. 10.—Plan and Elevation of the 120-K.W. Castle Dynamos, coupled to Willans I I Engines.

Digitized by Google

Suitable supports or slings are also provided for the steam-pipes in the boiler-house. There are some 16 valves in all in use on the steam rings, varying in diameter from 7in. downwards. The slope of the steam-pipe is so arranged throughout that all water which does not flow back to the boilers can be taken off by one or other of the drain valves. All steam joints throughout the system are made with stamped corrugated gunmetal rings. The exhaust-pipes lie round the engine block in the positions shown in Fig. 4. The pipes next the engines (vertical bends) are of copper in every case, and all the other pipes are of cast iron, with turned flanges and faced joints. Each engine is supplied with an approved exhaust (sluice) valve. Arrangements are also made that the exhaust steam can be discharged directly into the atmosphere without passing through the feed heater if necessary. The main exhaust-pipe is carried up beside the wall of the pump-house in the position shown, Fig. 4. It is a galvanised wrought-iron pipe, $\frac{1}{8}$in. thick, and having a diameter of 10in. inside. It is made in lengths of about 10ft. each, the joints being made by flanges of $1\frac{1}{2}$ by $1\frac{1}{2}$ angle iron riveted on. A drain-pipe is provided at the lowest point in the exhaust. This is connected, together with the drain from the heater, to a common drain-pipe, which is led to the main drain of the boiler-house.

Steam Dynamos.

The whole of the generating plant in the engine-room (Fig. 9) in the first contract was supplied by the Electric Construction Company, of Wolverhampton. The additional plant since laid down was supplied by Messrs. J. H. Holmes and Co., of Newcastle-on-Tyne. The engines are Willans's central-valve compound type, of which there are now seven in the station—*i.e.*, two of the E E size, indicating 38 h.p. at 520 revolutions; three of the G G size, indicating 80 h.p. at 440 revolutions; two of the I I size, indicating 200 h.p. at 350 revolutions. Each engine is provided with a governor, so adjusted that if half the whole load be suddenly thrown on or off the variation of speed does not exceed 5 per cent., and that under no condition whatever does the engine race injuriously. Further, as the regulation of the dynamos is mainly carried out by an alteration of the resistance in the shunt, the governor is so proportioned as to maintain control over the speed of the engine throughout its whole range from no load to full load. Each governor is readily adjustable while the engine is running at various speeds. Each engine is fitted with a speed indicator, and also with a steam-pressure gauge in a convenient position, connected to show the pressure of steam in the high-pressure valve-chest. Sight-feed lubricators also are provided with each engine.

All the dynamos made by the Electric Construction Company are of the simple shunt-wound continuous-current type with drum armatures. There are five of these dynamos in all, having corresponding parts strictly interchangeable. In the design of the machines special attention has been given to the accessibility of the various parts for ready renewal, repair, or adjustment, to the arrangements for lubricating the outer bearing, to the stiffness of the spindle and its mechanical connection to the armature, and to the insulation of the sections of the armature and commutator throughout.

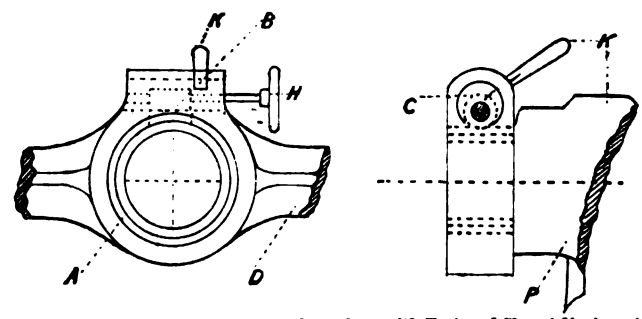

Fig. 11.—Sketch of the Holmes Brush Rocker, with Fast and Slow Adjustment.

The connection to the commutator are such that the brushes in their normal position are approximately horizontal. The brush-holders have both a quick and a fine adjustment. Three of the dynamos have an output of 210 amperes at 230 volts (or, say, 48 kilowatts) when running at a speed of 440 revolutions per minute. These dynamos are capable of running steadily at any E.M.F. from 220 to 275 volts, and are used to supply the outside wires of the three-wire system. The two smaller machines are respectively connected across from the two outer wires to the centre wire. In this way they balance the circuits, and also at moderate loads can supply the whole of the power required. These two dynamos have an output of 170 amperes at 135 volts (or 23 kilowatts) when running at a speed of 520 revolutions per minute.

The two large dynamos of the Castle type have most of the characteristics stated above. A view of these sets is given in Fig. 10. In these dynamos, made by J. H. Holmes and Co., the armatures are drum wound, and connected in such a way that the brushes are horizontal. The brush-rocker supporting the brush arms, etc., is arranged to have both a fast and slow adjustment in the following in-

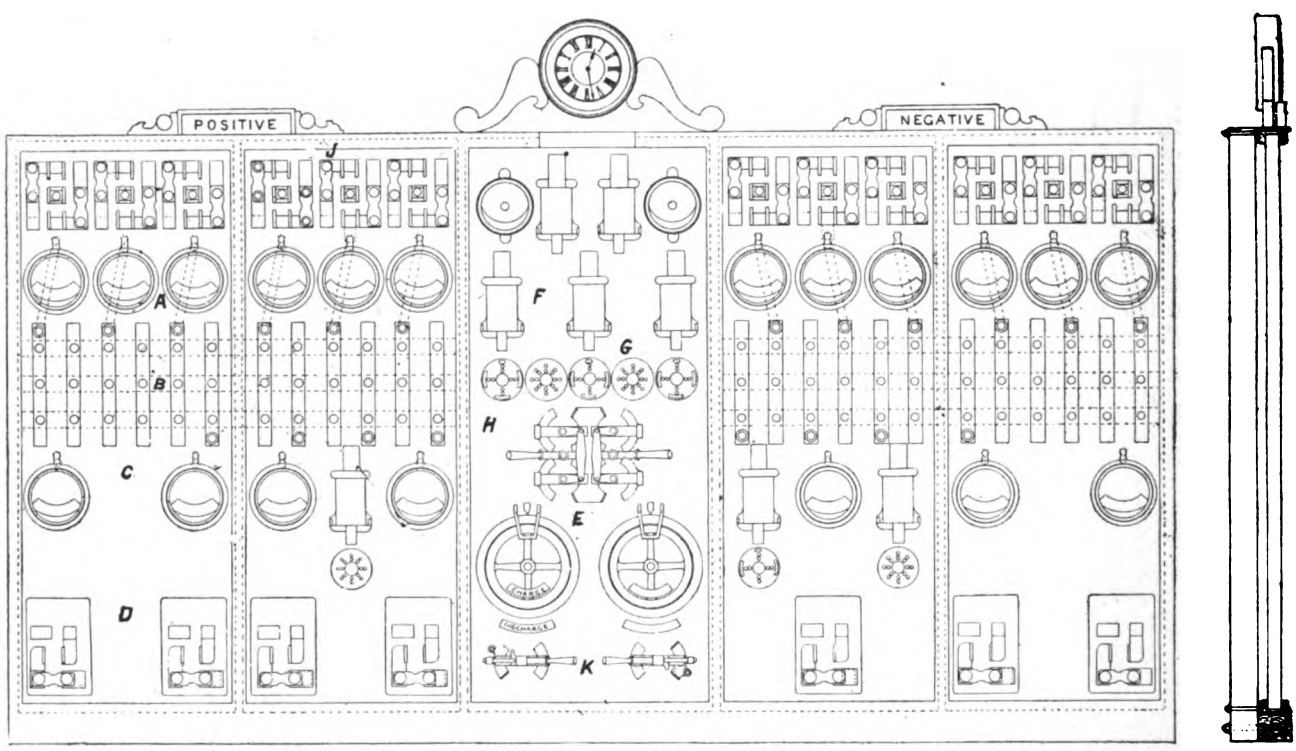

Fig. 12.—Elevation and Section of the Switchboard made by Siemens Bros. and Co.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

STREET-LIGHTING.

There are such a number of traditions, financial and otherwise, binding electrical engineers in matters of street illumination, that the question is seldom considered from a practical standpoint. We cannot understand why the lighting committees, after having paid for an inferior light for years at a fair rate, should expect to get ten times the light for about the same money. Such is the expectation where cost is considered, and the result in such cases is either that the electric lighting company or department has to supply a good light at a price totally unremunerative, or that the arc lamps are scattered about the town like needles in a haystack. In some towns, where the engineer has not hesitated to curtail the number of lamps, the streets can hardly be said to be electrically lighted. In one case we had under our notice lately, the lamps were placed so far apart that when standing under one lamp you would not see the next. This fault is due primarily to financial considerations, and yet when the townspeople demand that it shall be rectified endless trouble will ensue. One more lamp placed midway will then give too large a total, so that many lamp-posts now fixed will have to be moved, and in this way additional charges will be incurred. We should advise that good and permanent arrangements for the efficient lighting of a few streets should be made rather than any temporary arrangement of lamps. The other extreme has not been so much to the fore, and few towns or districts have put down large arc lighting schemes regardless of expense. Some few authorities have done so, and now are finding that, although they get a much better light in their streets, the people do not relish the increase in the rates corresponding to the increase in illumination. The result will be as before, that a reorganisation in the position of the lamps has to be made, which is both expensive and troublesome. At Hampstead, for instance, lamp-posts are being moved, and at Londonderry the Council is considering a private supply scheme to help bear the expense of the street-lighting plant. Unfortunately, the best arrangement of lighting streets economically has not yet received quite the attention it should at the hands of our leading engineers, and few facts of actual illumination have been published. The fact that the human eye accommodates itself to the lighting conditions and is incapable of gauging the actual illumination, militates against exact practice. As only relative sensations can be appreciated, it follows that very brilliant contrasts should be avoided. Hence, although frosted and corrugated glass globes absorb a good percentage of the light emitted by the lamps, they give a more pleasing general effect than clear globes. The great contrast between the brightness of the arc with the clear globe, and surrounding street, depreciates the actual illumination obtained. This objection of course vanishes, to a large extent, when high masts are used. This mast-head system is, however, not applicable to street work except in the case of wide, open spaces. A good arrangement not yet in actual

Digitized by Google

work in England, although we understand that at Brighton the engineer has determined to adopt it, is that of suspending the lamp over the centre of the street. In this way, as described by our Munich correspondent, the lamps are situated uniformly where they are wanted, and streets are lighted more evenly than by any other method. Another advantage of this method is that the switching out of alternate lamps at midnight does not disturb the equality of the lighting. In conclusion, we would state our conviction that good and efficient lighting of the public streets can be carried out with arc lamps better than with any other illuminant, and we trust the day is not far distant when the cost of such lighting will cease to be such an unprofitable item in the balance-sheets of many electricity works.

CORRESPONDENCE.

Justice needs that both be heard."

RE STARTING DIAGRAM.

SIR,—I notice in your article of August 30 that the Fig. 6, giving a diagram of starting *single*-phase motors on a single-phase alternating-current secondary circuit arranged after the three-wire system, is marked as being a starting arrangement for *three-phase* motors. Kindly correct this little error in the next issue, and oblige—Yours, etc.,

E. KOLBEN.

84, Weinbergstrasse, Zürich, September 2, 1895.

ABERDEEN ELECTRICITY WORKS.

(Concluded from page 265.)

The arrangement for putting the worm out of gear is as follows: The spindle is mounted eccentrically in a bush, C, as will be seen in the side elevation. When this bush is turned round by the handle K, the eccentricity of the worm spindle causes it to be raised up out of gear. The brush arms can then be rotated freely by hand.

These two dynamos, when tested at Messrs. Willans and Robinson's works, gave the following efficiencies and steam consumption:

Load.	Efficiency, *i.e*, $\frac{\text{E.H.P.}}{\text{I.H.P.}}$	Water per E.H.P. hour.
Full load	84·5 per cent.	24·32
Three-quarter load	78·44 ,,	28·9
Half load	72·5 ,,	33·64
Quarter load	60·15 ,,	50·48

These trials were made non-condensing at the normal boiler pressure. After a six-hour continuous run at full load, the temperature rise on the engine end of the armature was only 48deg. F. The temperature at the other end of the armature was only 30deg. F. above that of the atmosphere, and the rise in the magnet coils was 22deg. F.

The leads from the dynamo terminals are carried across through the engine block in wrought-iron pipes, suitably curved to allow insulated cable to be pulled through. Separate pipes are provided for the leads to the shunt resistances. A resistance is provided for the shunt of each dynamo, so that the regulation of the machine under all ordinary conditions can be carried out by an alteration of the field. This resistance is made of coils of German-silver wire, and its switch has about 25 contacts. The switches for the shunt resistances are placed in front of the switchboard. The added resistance is such that when the dynamos are running at full load at normal conditions, it does not fall below two ohms for the smaller and three ohms for the larger machines. The arrangements of the engine governors allow the steady speed of the dynamos to be various within somewhat wide limits, so that at low loads the machines run slower than at high loads, in order to let the work per revolution vary no more than is absolutely necessary.

BATTERIES.

The battery-room (Fig. 3) contains two batteries, each of 65 E.P.S. K-type cells. The lead tanks contain each 16 positive plates, and are capable of discharging at 150 amperes, and the batteries have a total capacity of 1,000 ampere-hours. The regulating cells are connected by bare copper rods to the switches, which are situated in the battery-room immediately above the main switchboard. The charge and discharge switches of each battery are enclosed in airtight cases, with glass fronts, to prevent corrosion by the acid fumes. Each charge switch has 13 contacts, the discharge having 18, and are worked from handwheels on the centre slab of the switchboard in the engine-room, the switches and handwheels being geared by means of bicycle chains. Eight spare cells are provided for milking purposes and also meter testing. The room is well lighted and ventilated, and has an acid-proof asphalte floor. A large sink with a water-tap is provided, together with hose and syphons, for emptying and filling the cells.

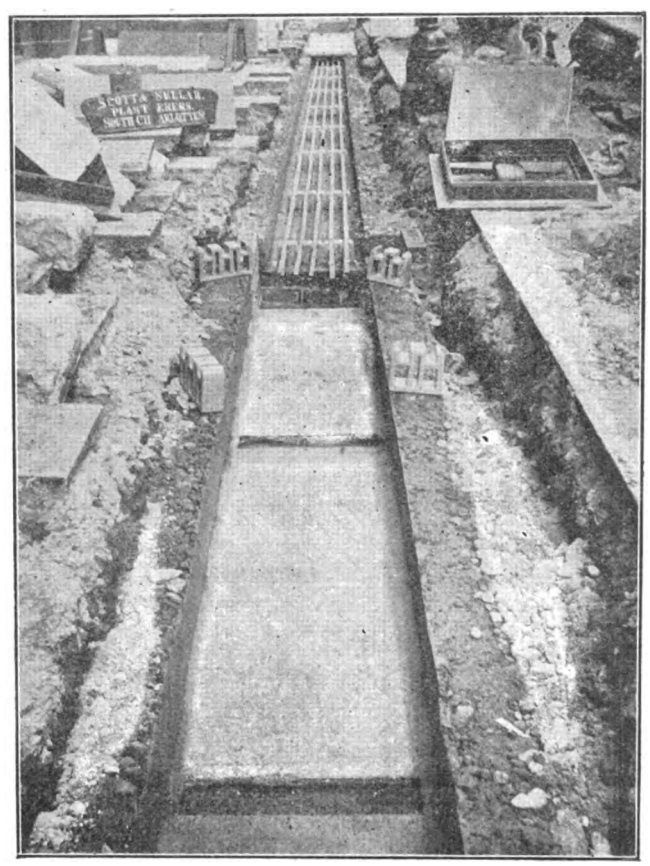

FIG. 15.—Mains in Course of Construction.

There is also a crane outside for raising carboys of acid, boxes of lead plates, etc.

SWITCHBOARD AND CONNECTIONS.

The switchboard (Fig. 12), which is of enamelled slate, was constructed by Messrs. Siemens, and is arranged in panels to enable extensions to be made at any time. The cables from the dynamos are brought along channels in the engine-room floor to the foot of the board. At the back are arranged three horizontal bars, B, the upper being the discharge bar for running direct on circuit, the middle the charge bar for the battery, and the lower being provided for testing purposes. The various dynamos and feeders are brought to vertical bars on the front of the board, and by means of plugs any dynamo or feeder can be connected to any of the horizontal bars at the back. Each dynamo is provided with an automatic cut-out, D, and ammeter. Ammeters and switches with duplex fuses, J, are placed on the feeders. By means of two-way switches, H, either of the two balancing machines can be placed on the positive or negative side of the system, or both can be placed on the

Digitized by Google

same side. The voltmeters are of Lord Kelvin's electrostatic multicellular type, and two of his ampere-gauges are used for the largest size of dynamo. Pilot wires are brought back from each feeding point of the network, so that the attendant has practically the voltage of supply before him. The shunt resistances for the dynamos are placed in a pit under the switchboard platform, the switches being on the platform rail immediately in front of the respective dynamo ammeters and automatic cut-outs, this arrangement greatly facilitating the switching-in of the dynamos. The battery-regulating switches are worked from the switchboard by means of wheels placed concentrically on the board and provided with chain gear, the switches themselves being in the battery-room. Along the walls beside the switchboard are placed the Aron meters for the batteries and dynamos.

permanent insulation. In places where the depth of the pavement will not allow of culverts being laid, and where the circuits cross the roads, Crompton-Davis three and five way iron casing is used. The copper strip was supplied by Messrs. T. Bolton and Son, of Staffordshire. Some 40 tons of copper have been used, of sections 1in. by ·250in. and 1in. by ·200in., in lengths of 200ft. to 250ft. Armoured cables are laid in the roads in a few cases where there is not room in the sidewalks.

Most of the cables for this work were manufactured and supplied by Callender's Bitumen Telegraph and Waterproof Company, Limited, and were laid by the Corporation themselves. They consist of armoured and unarmoured cables. The unarmoured cables were insulated by means of vulcanised bitumen, put on in one solid sheath under hydraulic pressure, and finished off by means of tape, yarn,

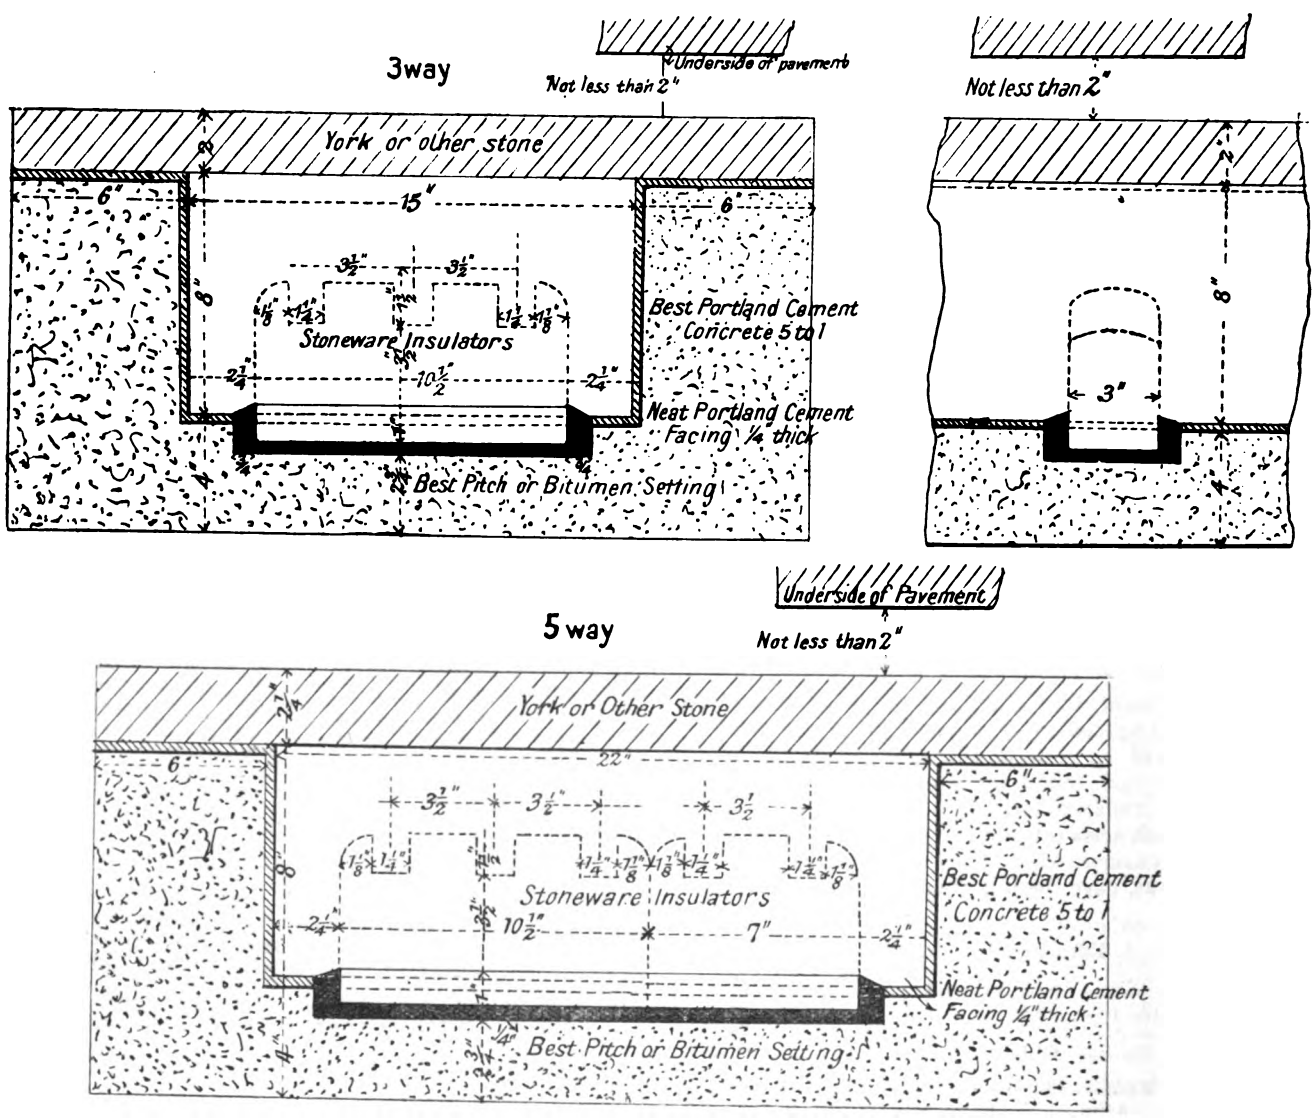

Fig. 14.—Sections of Conduits for 3-way and 5-way Mains.

Mains.

The mains, of which there are about five miles, are laid, as will be seen from the plan (Fig. 13), in the leading business streets of the city. Prof. Kennedy's system of bare strip laid in culverts is used for the network and part of the feeders. The strip is supported at intervals of 6ft. by porcelain insulators, which are fixed to the bed of the culvert by pitch. Fig. 14 shows sections of three-way and five-way culverts as actually laid on this system, and Fig. 15 is a view of the mains under course of construction. The whole of the insulators were supplied by Messrs. Doulton and Co., of Lambeth, and are of their well-known highly-vitrified stoneware. Between three and four thousand insulators have been used. They are of similar pattern to those that have been supplied by this firm for the Oldham, Belfast, Sunderland, and Edinburgh schemes, where they have given every satisfaction. The material and design of these insulators are both such as to ensure high and

and braid. The armoured cables were insulated by means of a dielectric of vulcanised bitumen, then lead sheathed, yarned, and armoured by two steel tapes, finally served over all with a double layer of jute yarn thoroughly impregnated with bitumen. These cables have now been in work for some considerable time, and the orders for the extensions now being made in Aberdeen have also been placed with the Callender Company.

of their paper-covered cables for street work. The section of the whole of the network, including both strip and cable, is ·2 square inch.

Demand for Light.

Since the opening of the station in February, 1895, the demand for light has rapidly increased. The increase in the equivalent number of 8-c.p. lamps connected during the last year is as follows:

Date.	Lamps connected.
August 1, 1894	4 348
September 1, 1894	4,964
October 1, 1894	6 470
November 1, 1894	7,389
December 1, 1894	8 010
January 1, 1895	8,440
February 1, 1895	8 660
March 1, 1895	9,067
April 1, 1895	9,350
May 1, 1895	9 560
June 1, 1895	9,624
July 1, 1895	9,827
August 1, 1895	10,327
September 1, 1895	10,900

Applications for the supply of current are coming in steadily. Many of the principal buildings are already coupled up, or are at the present time being wired. These include the Town House and Municipal Buildings, the new Police Offices, the Incorporated Trades' Hall, Robert Gordon's College and Gray's School of Art, and Marischal College. The latter fine building, at present being wired by Messrs. Shirras, Laing, and Co., of Aberdeen, will be a very fine installation. The picture gallery alone will be lighted by 170 16-c.p. lamps studded in panels over the ceiling. It is expected a very fine effect will be thus obtained; this also is a feature of the lighting of the large banqueting-hall, which has 206 16-c.p. lamps. The total number of lamps coupled to the mains is over 11,000 8-c.p.

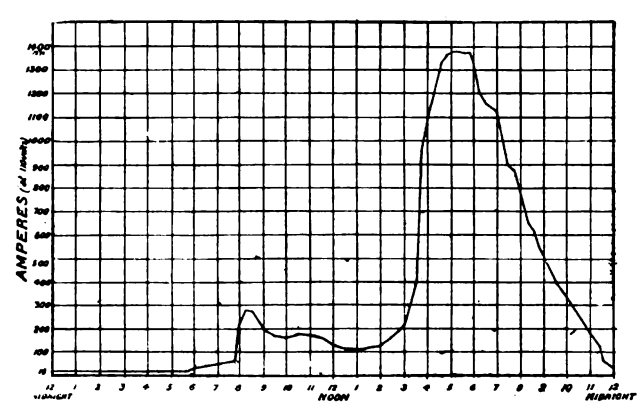

Fig. 16.—Load Diagram, Dec. 24th, 1894.

The load diagram (Fig. 16), reproduced, was taken on December 24 last, and shows the highest load yet attained—viz., 1,370 amperes at 110 volts. The number of 8-c.p.

Digitized by Google

lamps on circuit at that time was only 8,440. The area supplied is composed almost entirely of shops and offices, most of which close between the hours of 5 and 8 p.m., thus causing the large peak observed. The extension of the area of supply into the residential district will considerably alter this, and will also produce a larger load between the hours of midnight and 8 a.m.

A showroom of electric motors is now being organised by the engineer to induce the users of power to employ motors for their work, and thus to increase the day load.

We give herewith a copy of the accounts for year ending July 31, 1895, and also for the first 10 months after the station started working. Although with the system of book-keeping adopted a total loss of £401. 9s. 10d. is shown for the whole period, we consider that the station is for all practical purposes a financial success, and that such should be the case so soon after starting is very creditable to all concerned. While admitting that machinery and buildings do depreciate, we consider that when a station is charged with the repayment of loan in the shape of a sinking fund, and the machinery is kept in repair, that the depreciation items are doubly charged. The facts of the case before us are as follows: For the year the station showed a gross profit of £1,815. 17s. 10d, of which some £1,195 was required for interest and repayment of loan. This practically amounts to a net profit of £620. 17s. 10d. on the year's working. £720 is a substantial amount to write off a capital of under £25,000, and at this rate in a few years the Aberdeen Electrical Department will be very well off as regards capital charges. The improvement in the cost per unit during the two periods is very marked. The total cost of generation has been reduced from 2·94d. per unit to 2·35d. per unit. The cost of fuel now stands at the low figure of 0·49d. per unit generated, and at 0·54d. per unit sold. These figures will compare well with those of any station in the kingdom.

The efficiency of distribution is also good, as it stands at 91·5 per cent. for the current year, in which only 10,338 units were unaccounted for out of some 118,193 units generated.

The present Gas and Electric Lighting Committee consists of the following gentlemen, and they are to be congratulated on the results of the year's working: Councillor Johnston (convener), Lord Provost Stewart, Treasurer Bisset, Councillors Fleming, Glass, Gray, Mundie, Sangster, Skinner, and Young.

A feature of the station working is the complete system of book-keeping and reports adopted. Besides a very complete and full weekly report, and the usual log sheets, there is a daily report book kept, which is made up every morning by the assistant responsible for the run the night before. This gives hours of running, the number of units generated for the day, full particulars of the charge and discharge of the batteries, the cost of generating per unit under the headings of "Fuel," "Water," and the various engine-room stores, each item being worked out separately. The pounds of water evaporated per pound of fuel, together with the names of the drivers, stokers, and switchboard attendants on the shift are also given. By this means the chief engineer is able to at once check and rectify any irregularity in the working of the station almost as soon as it occurs.

NEW CATALOGUE.

Messrs. Johnson and Phillips, of Charlton, have just issued a new catalogue of cable-making and wire-covering machinery, which is, as far as we know, the only publication dealing so fully with this class of machinery. It differs, however, in one respect from all previous catalogues which have passed through our hands in that the price columns are everywhere left blank. We welcome this publication, therefore, as a descriptive list of the machines for special work, and feel as much in the dark as ever as to the cost of the cable-making machines. The illustrations are excellent, and we are able to reproduce three typical examples.

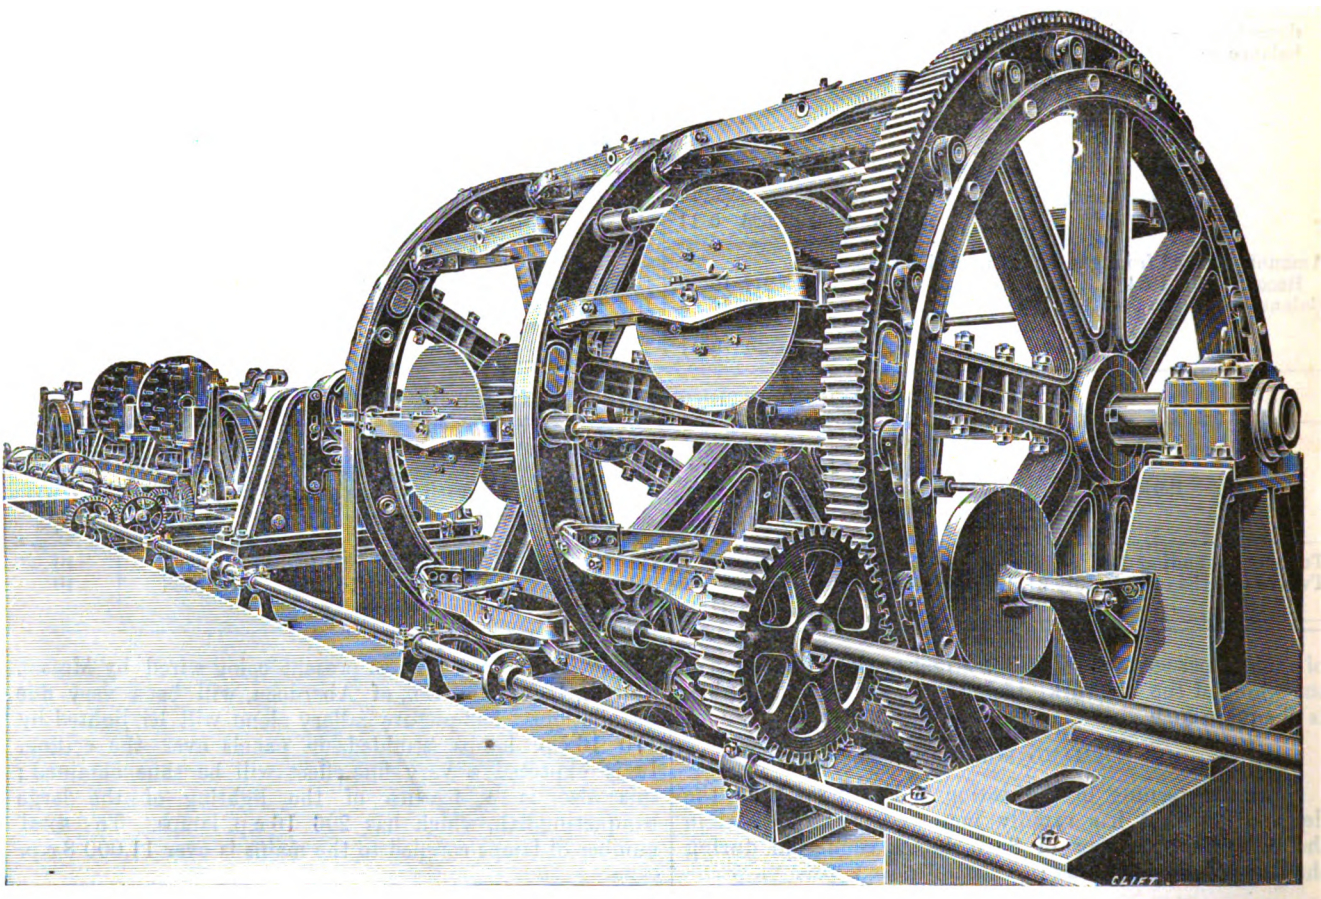

FIG. 1.—Submarine Cable Sheathing Machine.

It seldom falls to the lot of one firm to be both manufacturers and users of the same machines, but when it does, as in the present case, the experience gained by the actual working of the machines will naturally result in the best design to fulfil the requirements of the work to be performed; and in this connection it will be noticed that the particulars of the output of the various machines are given, a departure which is a good feature.

Digitized by Google

Fig. 1 is a sheathing machine with 18 bobbins, 36in. diameter, for sheathing "shore-end" cables with iron or steel wires, and serving them with protective coverings of yarns, tapes, and compounds at one operation. The complete machine includes engine and counter-shafting for driving the various parts, two draw gears, two yarn-serving discs, two taping heads, three compound tanks, and one set of bobbins, but machines can be supplied with only one draw gear and with apparatus for any number of servings. The whole machine takes up a space 88ft. long by 16ft. broad, and each of the 18 bobbins can hold 24cwt. of iron wire. A separate engine is provided for driving the machine, but it is not shown in the illustration; it is fixed at this end of the machine, and is connected by means of gear wheels to the shaft shown in the front part of the engraving. The bobbins are 3ft. in diameter, and each one is provided with a steel friction strap to regulate the tension on the wire as it is being drawn off. They are arranged in two bays of nine each, and are supported in massive flyers, composed of wrought iron and steel, which are carried in three large cast-iron discs. These discs are 11ft. 9in. diameter, and they are made in halves for convenience in transit, and held together with bolts and wrought-iron hoops. The bobbins are kept in the horizontal position during the working of the machine—thus preventing twist in the wires themselves—by means of an eccentric ring, which is hung from cranks attached to the ends of the flyers. This machine is said to be the largest yet made for the above purpose.

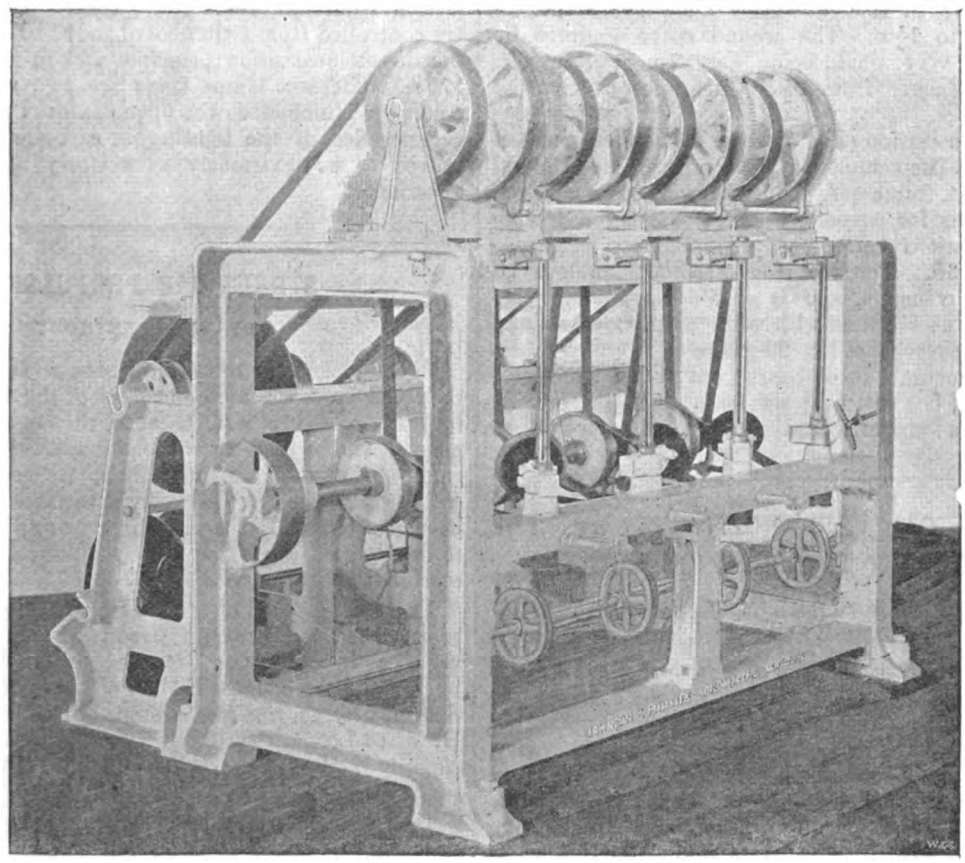

FIG. 2.—Vertical Multiple Rubber Lapping Machine.

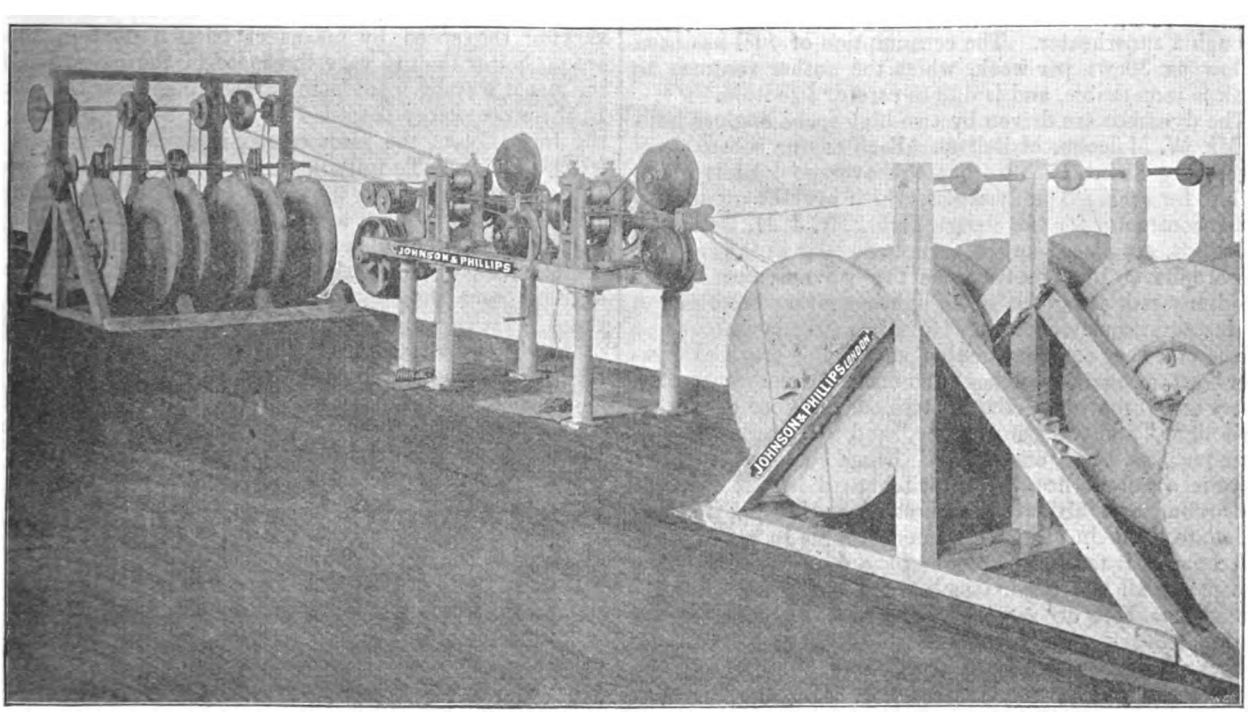

FIG. 3.—Complete Longitudinal Rubber Covering Plant.

Fig. 2 is an illustration of a multiple vertical rubber-

Digitized by Google

lapping machines for electric light wires. These machines are designed for covering the single wire or stranded copper conductors with pure rubber tape, and they are suitable for strands up to $\frac{3}{8}$in. diameter. Each machine has four heads, which can be stopped independently of each other, and is provided with change wheels for varying the lay from about $\frac{1}{4}$in. to $1\frac{1}{4}$in. The ground space occupied by the machine is very small, being only 7ft. 6in. by 6ft. Each head will cover from $2\frac{1}{2}$ to $3\frac{1}{2}$ miles of wire per working day.

The other illustration (Fig. 3) is of a complete rubber-covering plant. The complete plant comprises longitudinal covering machine, frame and drums for wire to be covered, frame and drums for covered wires, with friction driving gear and automatic traverse gear. The diameter of drums for the wires is 3ft. The covering machine combines all the latest improvements, and is capable of covering six wires or strands at one time with white or black compound rubber. It will cover from No. 20 gauge wires up to cables 1in. outside diameter. It, of course, only takes one cable of this diameter, but will take six leads up to $\frac{3}{8}$in. outside diameter, and a proportionate number of intermediate sizes.

THE ELECTRICAL ARRANGEMENTS AT THE BELFAST FIRE STATION.*

BY JAMES MUNCE, A.M.I.C.E., M.S.I., ASSISTANT CITY SURVEYOR.

The system of electric bells is so arranged that the duty man can call any individual, or, by turning a lever, the whole staff at once; a sick man or one off duty can be left undisturbed. The station is lighted entirely by electricity, the current being generated on the premises. A very compact Lancashire boiler, made by Galloways, of Manchester, supplies steam not only to the engines for driving the dynamos, but also to a separate engine for the work-shops, for boiling hot water in the cistern which supplies each of the 25 houses, laundry, single men's quarters and superintendent's house, and steam to the heating coils in duty-room, engine-house, gymnasium, etc. It is kept at about 40lb. pressure during the day, and at 80lb. whilst the electric light is turned on to the whole station—*i.e.*, to 11 p.m. The exhaust steam is used for heating the feed water which is pumped into the boiler by a Worthington pump, through a superheater. The consumption of fuel has been as low as 30cwt. per week, which the author ventures to think is remarkable, and is due to careful attention.

The dynamos are driven by two high-speed engines built by Mr. W. Malcolm, of Belfast. Each engine is capable of developing about 18 h.p., but the average load is about 10 h.p. for each. The dynamos, which are the production of the contractor for the electric light, Mr. J. H. Greenhill, of Belfast, are placed on the same bed-plates as the engines, and are driven by belts from the respective flywheels. To avoid any risk of failure in the lighting, either machine can be instantaneously connected to any particular circuit by means of a very complete double-pole, double-break "throw-over" set of main switches, also made by the contractor. There are three main circuits, termed the "ordinary," the "all-night," and the "emergency," and these terms explain their purpose, the "emergency" being switched on when there is a call of fire. The switchboard is placed in the duty-room, and although at first sight it appears very elaborate, it is in reality extremely simple to manipulate, and renders it totally impossible for a mistake to be made. It contains all the Corporation's telephone wires, the direct fire alarms, bells to each apartment and dwelling in the station, electric light switches, speaking-tubes, etc., also gauges showing the pressure of the town water supply and the electric light volts and amperes. In short, the duty man at the switchboard has control of the lights, bells, and telephones of the whole establishment and the out-stations as well. The ordinary lights are switched out at 11 p.m., but there is an additional switch for each lamp in the dwelling-houses and in other sections, by which any lamps not required may be cut off. When the fire alarm rings, the "emergency" switch is operated, and instantaneously the special lights in the fire-engine room, stables, single men's quarters, and one light in each of the married men's houses are illuminated, so that no delay occurs in any section from want of light. These "emergency" lights are controlled from switchboard only. The current is on the direct low-tension principle, and in addition to about 170 incandescent lamps there are two very powerful arc lamps for illuminating the open spaces of the station. The general effect of the lighting is extremely fine, and it has proved to be extremely satisfactory after two winters' experience.

* Extract from a "Description of the Headquarters of the Belfast Fire Brigade," read at the Londonderry meeting of the Association of Municipal and County Engineers.

STREET-CAR PROPULSION.

BY W. A. ANTHONY.

In the operation of electric cars, it is well understood that benefits of the high efficiency of the electric motor are in great measure lost, because the motor does not, in general, run at its most efficient speed. The desirability of running the motor continuously at its best speed, and controlling the speed of the car by a variable gearing, has long been recognised, and numerous attempts have been made to devise such a gearing that should stand the wear and tear of street-car service.

The ideal method of obtainable variable speed would be to drive the motor from a circuit whose voltage could be varied as in the system proposed by H. Ward Leonard, or by varying the counter E M.F. of the motor as was done by Sprague, by varying the strength of the field magnets. The H. Ward Leonard system is a costly outfit, and it is impossible by varying the strength of field to obtain the necessary range of speed.

It was not my object to discuss here the electrical methods of speed control, but rather to consider the problem of obtaining a variable speed on the car from a constant-speed motor. Any system of gearing for varying the speed must, to meet with favour, be simple, durable, and certain in action, and must operate without waste of power. It should also vary the speed from zero to the maximum by a continuous gradation. Many of the methods that have been proposed are faulty because of their inefficiency. Of this class are all the plans for varying the speed by means of friction devices. These are no better than to vary the speed of the motor itself in the usual way by introducing a resistance into the circuit. In this case energy is wasted in heating the resistance. In the former case, the same energy is wasted in heating the friction clutch. To fully understand this, it is only necessary to consider that in starting a car and bringing it up to speed, at least as great a "torque" is required as to maintain its speed after full speed is reached. During all the time, therefore, that the car is coming up to speed, the motor is exerting more than its normal force while running at full speed. It is therefore delivering more than its rated power, of which only a fraction is used in propelling the car, the remainder being consumed in heating the clutch.

Suppose, for instance, the car were running at only one-fourth the speed it will have acquired when the clutch ceases to slip, one-fourth of the energy delivered by the motor is then imparted to the car, and three-fourths to the friction clutch.

A liquid transmission has been tried where a pump is attached to the electric motor and a liquid motor to the car axle, the varying speed being obtained by allowing part of the liquid put in motion by the pump to pass by the liquid motor through a valve by which its amount could be controlled. A moment's reflection will show that this is only a sort of liquid friction clutch, and that it is open to the same objection. It is plain that the pressure at the by-pass valve must be the same as at the motor, and that the work done at each must be proportional to the amount of liquid passing through it. Where the car is being propelled at one-fourth speed, one fourth of the work done by the electric motor is expended upon the car axle, and three-fourths upon the liquid as it is forced through the by-pass valve. This latter simply goes

Digitized by Google

to heat up the liquid, and is wasted energy. It is plain that there is nothing gained by any such device. With the motors as they are now used, themselves varying in speed, the electrical energy at slow speed is expended partly upon the motor usefully and partly in the starting rheostat wastefully. With the motor and variable gear, as has been described, the motion of the constant-speed motor being transmitted to the car axle through a friction clutch or any equivalent, the electric energy is all expended upon the motor, but the energy of the motor is only partially transmitted to the car axle except at full speed.

Any device to fulfil the requirement must take from the line, barring the inevitable losses of transformation, only the power applied to the car axle. As the motor is only efficient when running at full speed, the variation of speed must be obtained by a variable gearing that does not consume power except in transmission. The difficulty has been to find such a gearing that would stand the rough usage of street-railway service. As an example of the kind of gearing required, though not as a practical solution of the problem, the motion of the motor might be transmitted to the axle through a pair of cones, the variable speed being obtained by shifting a belt.

A few years ago a liquid transmitter was proposed in which, as I remember it, a pump was placed upon the shaft of the electric motor and three liquid motors of different capacities were placed upon the car axle. These motors could be used singly or in pairs, or all three together, giving seven different speeds. This plan is entirely correct in theory; it is only a question how it would work out in practice. It has the disadvantage that the speed is varied by steps and not continuously. In another device, recently proposed, four reciprocating pumps are arranged radially at angles of 90deg. with each other, and actuated from the same crank upon the shaft of the electric motor. This crank has a variable throw, adjustable while in motion, from 1½in. on one side to 1½in. on the other side of the centre. When the throw is greatest, the pumps deliver the largest quantity of liquid and impart to the car axle the highest speed. When the crank pin is at the centre, no liquid is delivered and the car stops. With the crank pin transferred to the opposite side of the centre, the motion of the car is reversed. The speed may therefore be varied from full speed in one direction to full speed in the opposite direction by a continuous gradation, the electric motor continuing to run in one direction at full speed. This device is theoretically an ideal arrangement. It uses just the power needed at all speeds; it provides for changes of speed through all possible gradations from zero to the maximum, and the same operation carried far enough reverses the car. Moreover, when the car is at full speed, if the strokes be shortened, the speed of the electric motor is increased, and it becomes a generator, restoring current to the line, and acting as a very efficient brake to reduce the speed of the car.

If the crank pin be brought to the centre the pistons are held stationary, no liquid can pass through the pump, consequently the car axle cannot revolve and the car must be brought to rest. The motorman controls the entire movement of the car, starting, applying the brake, and stopping, by one handle, and by a means which makes the control absolute. He runs at any speed he likes within the limits for which the machinery is constructed; he diminishes and increases the speed at pleasure; having always a definite speed for each position of the controlling handle, he brings the car quickly to a full stop by simply bringing the handle to the zero position. Indeed so definite might be the speed of a high-efficiency shunt motor or a polyphase induction motor, that the dial of the controlling handle might be marked in miles per hour from zero up.

I say this is theoretically an ideal arrangement. Experiment must decide how it will work in practice. One difficulty occurs to me. Since there are four cylinders there is a constant pressure, and work constantly being done at all positions of the crank pin. To move the crank pin out from the centre must therefore require considerable force. An idea of the amount of force may be obtained by considering that if the electric motor were stopped with the crank pin at the centre, to move it outward would displace the pistons, force the liquid round through the liquid motors, and turn the car axle. The same work must be done to move the crank pin outward when the motor is in motion. Can this work be done by the motorman as rapidly as it would need to be done to control the car? Will a loose crank pin, controlled by a rack and pinion, stand the service that it must perform? Experience will tell.

LEGAL INTELLIGENCE.

DUBLIN AND BLACKROCK ELECTRIC TRAMWAY.

On September 3, before Mr. Justice Murphy, sitting as Vacation Judge, to hear motions for the Common-Law Divisions, in the case of the Pembroke Township Commissioners v. the Dublin Southern District Tramway Company,

Mr. Piers White, Q.C., with whom was Mr. T. C. Drury (instructed by Messrs. D. and T. Fitzgerald), said he appeared on behalf of the plaintiffs to apply for an injunction to restrain the defendant company from breaking up or excavating the roadway between the tram rails and the footpath in the township of Pembroke. Counsel explained that on the previous day the defendants, in connection with the laying down of their new electric tramway, commenced to break up the road close to the boundary of the Pembroke and Blackrock townships, in the face of the protest of the plaintiffs, in contravention of an understanding arrived at when the defendants were seeking powers in Parliament for the purpose of using electricity on their tramway, and in contravention of Section 14 of their Act, which gave them power to work the tramway by overhead wires only, whereas, as now alleged, they were about to sink cables in the roadway for the purpose of conducting the electric current. A letter, counsel said, had been received from the tramway company asking that the application should be allowed to stand to give them an opportunity of filing affidavits, an undertaking being given that the work objected to would not be proceeded with in the meantime.

Mr. Justice Murphy allowed the application to stand for a week.

BLACKPOOL CORPORATION.

The following is an abridged statement of the electric lighting accounts of the Corporation of Blackpool for the year ended March 25, 1895:

ELECTRICITY GENERATED.

Sold by meter	155,333
Public lamps	61,752
Used on works	6,334
	223,419
Magnetising, condenser, and main losses	54,008
Total apparent units generated	277,427

EXPENDITURE.

	£ s. d.	£ s. d.
Generation—Coal and coke, including unloading, terminal charges, shunting, repairs to siding, and siding rent	1,083 5 10½	
Oil and waste and sundry stores	345 6 4½	
Water	164 3 0	
Wages—stokers, drivers, electricians	916 15 9	
Repairs and maintenance of buildings, boilers, engines, dynamos, switchboard, and crane	161 5 6½	
		2,670 16 6½
Distribution — repairs to transformers, mains, meters, etc.		20 15 11
General—Salaries of engineer, clerks, treasurer; books, printing, stationery, and advertising	479 12 4	
Rent of land, rates, etc.	154 10 2	
Insurance, travelling expenses, testing new plant, inscription plate, postages, telegrams, refreshments, etc.	116 17 4½	
		750 19 10½
Special—cost of foundations, etc., for temporary plant, cable, etc.		76 6 3
Public lamps—attendance, repairs, carbons, painting lamp-posts, altering lamps to suit rectified current, etc.		357 15 10½
Interest	1,165 7 11	
Sinking fund	716 14 3	
		1,882 2 1
		5,758 16 6½
Less receipts		5,480 19 5½
Leaving net loss on year's working		£277 17 1

COMPANIES' MEETINGS AND REPORTS.

MILNER PORTABLE ELECTRIC BATTERY SYNDICATE, LIMITED.

The statutory meeting of this Company was held on Monday in Birmingham, Mr. Hyman Levetus presiding.

The **Chairman** explained that the Company was a private limited one—all the shares having been subscribed for. In regard to the construction of their battery, they had been told by experts that the difficulties of polarisation were insuperable, and that the cost of zinc was too prohibitive, but the impossible had been overcome. They did not use zinc at all, and as for polarisation, they did without it absolutely by means of the automatic circulatory system. The light would not exceed a cost of 6d. per Board of Trade unit The traction would cost 4d. per horse-power per hour—that is to say, they could have the work of a horse done for 4d. per hour. When this electric horse was not at work it cost nothing, and when charged it would run for 10 hours without refreshment. An invention such as this would do away with the cry for light railways. Every farmer could have his own produce wagon and take it along the roads at the highest rate of speed allowed by the authorities, at a cost of 4d. per hour per horse load. A battery could be supplied large enough to light a cathedral or small enough to carry in the hand as a bedroom candle. The Company hoped soon to exhibit a horseless carriage and electric lighting with Milner batteries. Meanwhile arrangements were being made to secure patent rights in 15 countries.

ELECTRIC CONSTRUCTION COMPANY, LIMITED.

Directors: Sir Daniel Cooper, Bart., G.C.M.G., chairman; James William Barclay, deputy-chairman; Philip Edward Beachcroft; John Irving Courtenay; Sir Henry C. Mance, C.I.E.; James Pender, M.P. Manager: A. B. Blackburn, M.I.C.E. Secretary: James Gray.

Report of the directors to be submitted to the shareholders at the second annual general meeting of the Electric Construction Company, Limited, to be held on Thursday, September 12, 1895, at Winchester House, Old Broad-street, E.C., at 2 30 p.m.:

The accounts for the year ending June 30, 1895, submitted herewith, show a gross profit of £46,690. 15s. 2d., including £2,260. 5s. 7d. brought forward from last year. Deducting from this amount interest, outlays on maintenance of buildings, plant, and patents, general expenses, and £5,000 for depreciation, the result is a net profit of £12,091. 10s. 3d., whereof the directors recommend that £1,956 14s 5d. be applied in payment of the dividend of 7 per cent. on the preference shares, and the balance of £10,134. 15s. 10d. carried forward to the credit of next account. The profit and loss account shows a considerable reduction of general expenditure, and, notwithstanding the keen competition prevalent, a substantial increase of manufacturing profit. Several important electrical installations have been successfully completed during the year, the production at Bushbury has increased, and the quality of the machinery and plant manufactured has been fully maintained. The directors have pleasure in reporting that the works are fully employed on orders at prices somewhat in advance of those obtainable last year, that the plant and number of the workmen have been increased, and that they are well satisfied with the efficiency and zeal of the staff and employés of the Company. Among the works in progress may be mentioned the important electric lighting installation at Clerkenwell and the electrical equipment of the Hartlepool tramways. It is confidently expected that the substitution at Hartlepool of electric traction for the steam power formerly used will prove that tramways heretofore worked by horse or steam power unremuneratively may be judiciously adapted for electric traction and yield a satisfactory return on the necessary outlay. Such a result cannot fail to give a great impetus to the development of electric traction in various directions. The directors who retire by rotation at the general meeting are Messrs. James W. Barclay and J. Irving Courtenay. They are eligible for re-election. Messrs. James Meston and Co., the auditors for the past year, offer themselves for re-election.

Profit and Loss Account, Year ending June 30, 1895.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Alexandria.—The municipal authorities of Alexandria, Egypt, invite applications by October 1, 1895 for the concession of the tramway lines from St. Catherine Place, through the outer boulevards, to the projected abattoirs at Mex, with a branch line. Security £E1,000.

Paris.—The Direction Générale des Postes et Télégraphes invite tenders by September 10 for the supply of 100 tons of copper wire and 24,000 tinned copper brackets; and by September 16 for making two air-conduits for the pneumatic telegraph service. The Cahier des Charges may be seen at rue de Grenelle, No. 103 (division du matériel et de l'exploitation électrique, 3ME bureau).

Braila.—The Municipal Authorities of Braila, Roumania, invite tenders by October 2 for the construction and working of a system of electric tramways in the city. Provisional security, 10,000f This contract was originally fixed for July 29. Tenders are further invited by the Municipal Authorities of Braila for the lighting of the city by electricity or by electricity and gas Provisional security 10,000f.

London, W.C.—Tenders are required for carrying out the work required in supplying and fixing wires, cables, and fittings for the installation of the electric light at their Board-room and offices, 57, Broad-street, W.C., for the Guardians of St Giles and Bloomsbury. Printed forms of tender can be obtained at the offices of Mr. James Appleton, clerk. where they must be delivered, sealed and endorsed "Tender for Electric Lighting," at or before 10 a.m. on September 10.

Chepping Wycombe (Bucks.).—The Urban Sanitary Authority for this borough are prepared to receive tenders from public companies for working the electric order obtained by them within the borough for a term of years and upon approved conditions. Tenders are to be delivered by noon on October 14 next, at the office of the town clerk, High Wycombe, where a copy of the electric order may be seen and further particulars obtained. The Authority do not bind themselves to accept any tender.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

Oldham.—The Baths Committee of the Oldham Corporation are prepared to receive tenders for supplying and fixing wires, fittings, etc, for lighting by electricity a portion of the Central Baths, Oldham. Specifications can be obtained from Mr S Willmott Newington, borough electrical engineer, Gas street, Oldham, on payment of 10s. 6d., which will be refunded on the return of the specification accompanied with a *bonâ fide* tender. Tenders, endorsed "Tender for Wiring," must be sent to the office of the town clerk, Town Hall, Oldham, before noon on September 11.

Shoreditch.—The Shoreditch Vestry invite tenders for—Section A—insulated electric mains; Section B—conduits and drawing-in boxes; to be laid in the parish of Shoreditch. Specification, with form of tender, can be obtained from the consulting engineers, Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster, on payment of three guineas, which will be returned on receipt of a bona fide tender. Tenders, endorsed "Tenders for Electrical Mains," to be sent by 17th September to Mr. H. Mansfield Robinson, vestry clerk and solicitor, Town Hall, Old-street, E.C.

Gravesend.—Tenders are requested for the supplying of a telephone, and providing, delivering, and fixing, etc., of the necessary poles, wires, instruments, and plant at regulation distance of a specified description, from the sanatorium to the office of the sanitary inspector and the police station, for the Town Council. Tenderers are also requested to specify an amount per annum at which they would maintain the communication. Further particulars can be obtained of the sanitary inspector, Town Hall. Tenders, marked "Sanatorium Telephone," must be delivered to Mr. Chas. E. Hatten, town clerk, Gravesend, by September 20.

Stafford.—The committee of the Staffordshire County Infirmary invite tenders for wiring and fitting the infirmary for electric light. Tenders, sealed and addressed to the Secretary, Staffordshire County Infirmary, Stafford, and endorsed "Tender for Electric Lighting," must be received by him not later than noon on September 14. Copies of the specification, with form of tender attached, can be obtained from the secretary on payment of £1, which will be returned on receipt of a bona fide tender; and plans may be seen on or after Monday, September 2, at the infirmary, or at the offices of the engineers, Messrs. Kincaid, Waller, and Manville, 29, Great George street, London, S.W.

Dundalk.—The Dundalk Town Commissioners invite tenders for erection of an electric lighting installation for the purpose of lighting the town by electricity on or about July 1, 1896, reserving to themselves the right of taking over the plant at the end of a term of years—this term to be stated in the tenders. The successful contractor to have the right of supplying private consumers, while the Commissioners will pay a fixed sum yearly for the town lighting—this sum to be stated in the tender also. The Commissioners have obtained a license from the Board of Trade for supplying electric lighting. Tenders will be received by Mr. Edward Farrar, town clerk, Town Hall, Dundalk, up to October 7.

Sunderland.—The Corporation of Sunderland are prepared to receive tenders for the following: (*a*) high-tension and low-tension concentric cables; (*b*) cast-iron pipes, and box frames and covers; (*c*) stoneware casing, boxes, and bellmouth protectors; (*d*) high-tension transformers for alternating current; (*e*) meters for alternating current. Specification, conditions of contract, and form of tender may be obtained on payment of £1 1s. at the office of the borough electrical engineer, Electric Supply Station, Sunderland. The deposit will be refunded on receipt of the specification and conditions of contract with a *bonâ fide* tender. Sealed tenders, addressed to the chairman of the Highways Committee should be delivered at the town clerk's office by 6.30 p m on Friday, September 13.

Queenstown (Ireland).—Tenders are invited by the Queenstown Town Commissioners for the lighting of Queenstown by electricity (private as well as public) as per report and specification of Mr. R. Hammond, M.I.E.E., Ormond House, London. Tenders are also invited as follows: the contractor to provide the capital for the due erection of the works and maintenance thereof as per above plans and specifications, on being guaranteed the public lighting, and a stipulated number of private lights (to be agreed upon), the Commissioners having the right to purchase within a specified period. Plans and specifications are deposited at the Hall, Queenstown, and can be inspected there between 11 and 2. Tenders must be lodged with the town clerk, Queenstown, marked "Tender for Electric Lighting," by 2 p.m. on September 16. Further particulars and conditions to be had on application to Mr. James Ahern, town clerk, Queenstown.

Manchester.—Tenders are invited for the execution of the following works, for the Manchester Corporation—(Contract 2) laying a system of underground telephone pipes, with brick inspection pits, service boxes, and other appurtenant works in the following streets: route 6—Little Peter-street, Chester-road, Hulme Hall road, to a point adjoining the Ship Canal. Laying a system of underground telephone pipes with brick inspection pits, service boxes, and other appurtenanant works in the following streets (Contract 3)—viz.: route 1—Dickenson street, South-street, Jackson's row, Deansgate, Atkinson-street, Byrom-street, Camp-street, Charles street; route 2—Dickenson-street, George-street, Nicholas-street Booth-street, Tib lane, Cross street, South King street, Deansgate Lower King-street, Ridgfield, John Dalton-street; route 2A - Pall-mall, Moult-street, Bank-street, Half Moon street; route 2B—Bank street, Exchange-street, St. Mary's-gate, Blackfriars-street, Parsonage; route 3—Faulkner-street, Charlotte street, Back George street; route 3A—Charlotte-street, Fountain street, Marble-street, High street, Cannon-street, Hodson's square; route 3B—High street, Nicholas croft, Bradshaw-street, Cross-street, Balloon-street, Holgate-street, Corporation-street, Mark-lane. Drawings may be seen, and copies of specification, bills of quantities, and forms of tender for each contract may be obtained on application at the city surveyor's office, Town Hall, Manchester, on September 9, on payment of £2. 2s. and £5. 5s. respectively, which sums will be refunded on the return of the documents and the receipt of bona fide tenders. Sealed tenders, enclosed in the official envelopes, to be sent in by 5 p.m. on September 17.

RESULTS OF TENDERS.

London, N.—For the wiring of the Vestry Hall and municipal offices in Upper-street, N. and for the supply of fittings, for the Vestry of St. Mary, Islington: S. Newton and Co., 15A, Baker-street, W., £215 (accepted). Note.—32 tenders received.

Belfast.—The Electric Committee of the Corporation have accepted the following tenders: Messrs. Shaw and Co. for cast iron, Messrs. Doulton and Co. for insulators, the Callender Bitumen and Telegraph Company for cable, the British Insulated Wire Company for copper strip, Messrs. Coates and Son for road-work Messrs. Robert Patterson and Son for inspection plugs, and Messrs. Wormald and Co. for covering exhaust-pipes.

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,038.

Direct Spanish Telegraph Company.—For the month of August the receipts were £1,957, as against £1,583 for the same period of 1894.

Easton-in-Gordano (Glos.).—The Parish Council have resolved that a committee be formed to enquire into the best means and cost of lighting the parish.

Wells.—The Town Council have retained the services of Dr. Hopkinson to advise them with regard to the electric lighting of the city, at a cost of £52. 12s. and travelling expenses.

Commercial Cable Company.—This Company has declared a quarterly dividend of 1¾ per cent., payable on October 1. The transfer books will be closed on September 20, and reopened on October 2.

Digitized by Google

West India and Panama Telegraph Company.—For the two weeks ended August 31 the receipts show a decrease of £181 as compared with the corresponding period of 1894.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 1st inst. amounted to £1,272, as compared with £1,152 in the corresponding week of last year, being an increase of £120.

Liverpool.—A meeting of the Special Lighting Committee of the Corporation has been held at which the engineer was instructed to report as to the lighting of the added areas in connection with the extension of the city boundaries.

The City Electric Light and Power Engineering Works.—We have received a copy of the new catalogue of dynamos, arc lamps, motors, and alternators issued by this firm (L. C. H. Mensing) from 89, Worship-street, London, E.C.

Tunbridge Wells.—The Lighting Committee of the Town Council have appointed Mr. E T. Stuart assistant electrical engineer, at £100 per year salary. The Mayoress (Lady Salomons) is to be asked to publicly open the new works, and it is proposed to hold an electrical exhibition in October.

Oswestry.—The Town Council have received a letter from the Oswestry Electric Lighting Company stating that the current would shortly be laid on in the proposed area, except Willow-street, and that the charge would be 7d. per unit.

City and South London Railway.—The returns for the week ended September 1 were £786, compared with £794 for the corresponding period of 1894, being a decrease of £8. The total receipts for the half-year 1895 are £7,669, compared with £7,735 for the corresponding period of 1894, being a decrease of £66.

Public Works in Natal.—The Corporation of Durban, Natal, have decided, it is stated, to raise £110,000 of stock for improvements in the town, to be expended as follows: £60,000 for a promenade, £25,000 for lighting the town by electricity, and £25,000 for the completion of the scheme for an adequate supply of water.

Mile End.—The Works Committee of the Mile End Board of Guardians have reported on the proposed lighting of the institutions of the Guardians by electricity, and recommend that the question be deferred for the present. Mr. A. Druitt moved, and Mr. Brien seconded, the adoption of the report, and it was agreed to.

Hull.—A meeting of the Hull Corporation Electric Lighting Committee has been held for the purpose of appointing an engine-driver. There were six applicants who appeared before the committee: J. T. Alton, E. Boyd, C. S. Hall, R. H. Harman, J. Morley, and J. N. Naylor. Mr. Alton was finally selected for the position.

Ship-Lighting.—The twin-screw steamer which Messrs. Lobnitz and Co. are about to build for the Japanese Government will be fitted complete with cable-laying gear of the most modern design by Messrs. Johnson and Phillips, and also with electric lighting plant and fittings for the whole of the vessel. We hope later to publish particulars.

Llanelly.—At the Llanelly Borough Council on Tuesday it was reported that the cost of lighting the centre of the town and the municipal buildings by electricity would be £10,000 It was moved and seconded that an electrical engineer be engaged to report as to the best method of carrying out the work, but an amendment was moved, it being contended that the time had not yet arrived, having regard to the experiences of other towns, for incurring the expense, and the amendment was carried by a large majority.

Eastbourne.—The Lighting and General Purposes Committee of the Town Council have resolved to recommend the adoption of the proposals of the Telephone Sub-Committee that the wires sent through the exchange be altered to pass through the police station, excepting those which were to remain on the exchange, that an additional line be connected from the police station to the destructor works, and that the estimate of the Telephone Company for carrying out the above alterations, amounting to £210, be accepted.

Newhaven.—On the report of the sanitary inspector a member of the Rural District Council has brought up the question of the lavatory accommodation that is being provided on the new pier at Rottingdean, erected by the electric railway company, and said it was proposed to empty the cisterns at high water. This proceeding the whole village objected to, as the landing-stage being immediately opposite where the bathing machines were, it was felt this would very materially affect the prosperity of Rottingdean as a bathing resort.

Wrexham.—A letter has been received by the Town Council from the Board of Trade enclosing a copy of a letter addressed to the secretary of the Wrexham and District Electric Supply Company, Limited, stating that the Board would defer consideration of the question of the revocation of the provisional order for a further period of six months from 15th ult., and adding that if at the expiration of that time the undertakers have not taken the necessary steps to give effect to the order, the Board of Trade will not be prepared to grant any further extension of time, but will proceed to revoke the order forthwith.

Belfast.—At the last Corporation meeting Alderman Haslett asked if the £25,000 lent to the Electric Committee was carried forward as a debt or not. Alderman Dixon said the sum referred to stood as a debt in the books. With regard to the electric undertaking, Alderman Haslett said that they were glad to see that it competed so favourably with gas, but he was inclined to think that it had not made anything like the same advance as some of the newer forms of gaslighting. They saw, for instance, the incandescent gaslight very rapidly coming to the front. At the same time, in a sanitary sense, electric lighting was far ahead of any other form.

Weymouth.—The directors of the Weymouth Waterworks Company, acting upon the advice of their engineers, Messrs. Crickmay and Sons, have instructed Mr. George Jennings, of Lambeth, London, to carry out an installation of his patent electrical indicating and recording apparatus between the reservoir and engine-house. By the adoption of this apparatus the level of water from the reservoir will be shown in the engine-house at all the hours of the day and night throughout the year, and a record of the varying depth will be automatically registered for reference. Mr. Jennings will also shortly fix a similar apparatus at the Great Yarmouth sewage pumping works.

Appointment Vacant.—The Electric Lighting Committee of the borough of Kingston-upon-Hull are prepared to receive applications for the appointment of a resident electrical engineer to take charge of their electric lighting station. The person appointed will be required to devote the whole of his time to the duties of the office, must be competent to advise upon the construction of all necessary works, the acceptance of tenders for the same, and to undertake the supervision of the works when completed. One who has had actual practical experience of central-station work will be preferred. Salary £250 per annum. Applications, with copies or prints of not more than three testimonials of recent date endorsed "Electrical Engineer," to be sent to Mr. R. Hill Dawe, town clerk, by Thursday, September 19.

Edinburgh.—The Town Council have received a letter from the general manager of the National Telephone Company suggesting that the Corporation should lay underground tubes for telephone wires at the company's expense. Sir James Russell said he did not think it was the least likely that the Council would entertain the proposal, which would only have the effect of confirming the telephone monopoly in the city. He thought the Council should give underground rights to no private company. The letter was sent to the Lord Provost's Committee. On a letter from the superintending engineer, Post Office Telegraphs, the Streets and Buildings Committee will report grant of permission to open the street on the south side of George street, the west side of South St. David-street, and south side of Princes street, for the purpose of laying an underground telephone line.

Portable Electric Lamp Company, Limited.—This Company has been registered, with a capital of £50,000 in £1 shares. Object: to acquire from William Morison and Andrew P. Morison, upon such terms as may be arranged, the benefit of a certain invention, entitled "Improvements in Portable Primary Batteries," and the letters patent granted in respect thereof (No. 9,826, of May 21, 1894; also the benefit of an invention or discovery of a composition suitable for the manufacture of the cases of the said batteries, and improvements therein, and of a chemical compound known as "electric sand," suitable for the generation of electricity, for use with the said batteries; also to manufacture, deal in, or let on hire steam, gas, and other engines, dynamos, machinery, cables, wires, batteries, electric motors, miners' electric safety-lamps, meters, instruments, fittings, and other electric appliances.

Dover.—The Harbour Board have decided to further improve the landing and embarking arrangements at the Admiralty Pier, by the construction of electric cranes for the transference of passengers' luggage between vessels and trains. The traffic between Dover and Calais and Dover and Ostend has grown so much lately that this convenience will often save 20 minutes more in the despatch of the mail steamers. At a special Council meeting Councillor Thorpe moved to rescind the contract with the Dover Electricity Supply Company for the lighting of Snargate-street. He argued that there would be a saving of £1,260 on the seven years if they adopted the incandescent gas lamp instead of the electric light. The Town Clerk advised that the Council would be responsible for any expense incurred by the electric lighting company if they broke their contract, and after considerable discussion the motion was lost by three votes.

Cork.—At a meeting of the Waterworks Committee the Chairman said that they spoke frequently as to the practicability of introducing electric light into the waterworks, but up to the present, owing to the cost of installations and lamps, it was always found too expensive, and there was also some difficulty about getting the necessary power to drive the dynamo. They were now getting their new turbines in, and during the winter months they would have a surplus power in their water-engines, and finding there was an electrical engineer at present in Cork fitting up the electric light in various places, he (the chairman) directed Mr. O'Toole (waterworks superintendent) to see him on the subject. He (the chairman) then had a conversation with Mr. O'Toole, and from the figures given him he had no doubt that they could effect a saving of £50 a year by adopting the electric light, in addition to having a much better light than they had at present. He would suggest that the matter be referred to Mr. O'Toole to report on. This course was adopted.

Tipton (Staffs.).—At the last meeting of the Urban District Council a letter was read from the town clerk of Wednesbury pointing out that the date by which the tramway company would have to apply for the renewal of the license for the use of steam would shortly expire, and suggesting the advisability of the local authorities through whose districts the tramway ran meeting in conference to discuss the matter. Councillor Steadman thought a conference a very good idea, for it would be a serious thing for the public if the trams were to stop running. Councillor Butler

Digitized by Google

said according to the shareholders' report the company did not seem to be in much of a position to provide any other mode of traction. Councillor Doughty thought the representatives of the Council at the conference should not pledge themselves to accept any particular mode of traction. At the last conference it was stated that they might favour overhead wires, but, personally, he should strongly object to overhead wires. They were very dangerous. It was ultimately agreed that the chairman, the clerk, and the surveyor should attend the conference.

Alderley Edge (Cheshire).—At the meeting of the Alderley Edge District Council, the accounts for the expenses incurred in obtaining the electric lighting provisional order were presented to the Council. The total was £272. 7s. 2d., and it was stated by the clerk that there was an addition to this amount of £50 paid to the Local Government Board. Dr. Burghardt and Mr. Church, councillors, objected to the amount, alleging that they had been given to understand that the order was only to cost £250 at the outside. Considerable discussion took place on the matter, and it was finally resolved to refer the accounts to the Finance Committee. A letter was read from Mr. S. V. Clirehugh, electrical engineer, of Manchester, offering to buy the provisional order from the Council, and stating that he was authorised by his clients to offer in return for the order to pay the costs incurred by the Council in obtaining it, and to say that his clients were prepared to supply electricity for lighting purposes at the cost of 32s. 6d. per lamp. The clerk stated that the cost per lamp at present was 35s. This matter was also referred to the Finance Committee for consideration.

Lancaster.—At the last meeting of the Town Council a letter was read from Mr. J. W. Pickard, objecting to carrying electric current wires forward from Haverbreaks Bridge to Oatlands, and suggesting that the Corporation should lay the wires, and he would pay interest on the capital outlay. It was resolved that the borough surveyor be instructed to lay cable mains to Oatlands of such capacity as he may deem advisable, subject to Mr. Pickard paying to the Corporation 10 per cent. per annum, for not less than six years, on the cost of the cable mains beyond Haverbreaks Bridge, such payment of 10 per cent. to be in addition to the usual charge for current. On the motion for the confirmation of the proceedings of the Electricity Supply Committee, Mr. Bowness referred to the unusually heavy cost of lamp-pillars and asked if the committee were obliged to go one firm for pillars of a registered pattern. Could not some other means be adopted which would reduce the cost of the pillars? Mr. Alderman Bell said originally the committee got estimates from four or five firms who made these pillars, and they accepted the lowest. An electric light pillar was a little different from an ordinary casting; it was of great length and had to be cast in a different way, so that this might add to the cost. The minutes were confirmed.

Ripon.—At the monthly meeting of the City Council a discussion took place with reference to the introduction of the electric light to the north end of Ripon, Messrs. Harrison and Co. having already installed public electric lamps at Ure Bank, across the River Ure, in the township of Sharrow. Councillor Lee said he should be sorry if the Corporation were to make up their minds to fight against the introduction of the electric light. The Town Clerk stated that the Corporation would have power to object to the introduction of the electric light. They might issue a license to any company, or they might promote electric lighting themselves. Councillor Lee urged that the supply of the electric light to Ripon would be a great boon. It could be brought across the river from Ure Bank at a moderate charge, and its introduction would be an advantage to the inhabitants and a step in the right direction. Councillor Husband urged that it was not merely a question whether the company was going to supply the electric light, but whether they were going to allow anyone else to supply it for private purposes. He moved that the subject be considered at a special meeting of the Council, and that in the meantime the gas company make a full report on the question. Councillor T. Wells seconded the motion, which was carried by seven votes to two.

Halifax.—The town clerk of Halifax has received from Messrs. Simpson and Marwick, of Heriot-row, Edinburgh, an application, on behalf of clients in that city, "for a concession conveying to them the exclusive right to construct and work a system of tramways in Halifax on the Hallidie cable principle." The subject was referred to the Tramways Committee of the Halifax Corporation, who, after discussing the project, passed the following resolution: "That it be a recommendation to the Council to favourably consider the application with a view to the introduction of tramways into Halifax, and that the assent of the Council be given to the request, on condition that an agreement embodying details satisfactory to the Council be executed by the company." It has been decided to spend a considerable sum in further extending the electric light at the Theatre Royal, and in rendering the house as safe and comfortable to the public as possible. The whole of the stage, orchestra, and other parts of the house are to be lighted thoroughly by incandescent lamps, numbering about 300 in all, and in addition the limelights are to be replaced by electric arc lamps of special design to enhance the scenic effects. The work is being carried out by Messrs. Walter Emmott and Co., who have already lighted the auditorium and the front of the house. In addition to the electric light, Grenell sprinklers are to be fixed, by which any risk through fire will be reduced to a minimum.

Woking.—A meeting of ratepayers has been held at the Westfield Schools to take into consideration the proposal of the Woking Urban District Council to light the village. Mr. Wooldridge, the surveyor, read an extract from a report to the Council on the subject, in which he said that from enquiries he had made he did not think the gas company would be at all disposed to extend their mains to the district which was now proposed to be lighted, as the cost of so doing would be very great. The electric supply company would be prepared to extend their mains a certain distance, but he thought it would be very unfair to light the village street and leave Westfield and Mayfield in the dark, seeing that the whole of the ward would have to bear the expense. The speaker then referred to oil lighting, and read estimates from which it appeared that the capital expenditure for lighting, partly with electric light and partly with oil, would be £127. 10s., and the working expenses £124. 3s., so that the annual cost of lighting in this way would be equal to a half-yearly rate of 3¾d. on the assessable value and 2¼d. on the ratable value. The next estimate was for lighting the ward entirely with oil. The capital expenditure in this case would be £85 and the working expenses £86 10s., making the annual cost equal to a half-yearly rate of 2¼d. on the assessable value and 1½d. on the ratable value. Resolutions were then put to the meeting from the chair, and it was decided that the lighting should be in the hands of the Urban District Council, and that the ward should be lighted wholly with oil.

Salford.—Mr. W. Bird Clerke, C.E., has held an enquiry at the Salford Town Hall, on behalf of the Local Government Board, with reference to an application of the Salford Corporation to borrow £18,000 for the purposes of electric lighting in the borough. Mr. Brown (the town clerk) stated that some time ago an application was made to the Local Government Board for power to borrow £50,000 for electric lighting, but £32,000 only was sanctioned, and the present enquiry related to the balance of that amount. The Corporation proposed to spend about half the sum almost immediately, and they hoped it would not be necessary to hold a further enquiry to obtain the sanction of the Board for the remaining £18,000. They trusted the Board would allow them to forward them the estimates for the further expenditure, and that upon being satisfied as to the correctness of those estimates they would sanction the borrowing of the sum required. The Inspector did not think the Local Government Board would sanction a loan for more than the Corporation definitely proposed. If they could submit a definite proposal for the balance of the £18.000, he, personally, saw no necessity for a further enquiry. Mr Edward Manville, the engineer appointed for carrying out the electrical lighting in the borough, explained some of the details of the scheme, and observed that the works had been carried out in accordance with the plans originally submitted to the Local Government Board. In regard to the present application, they could simply show an estimate of expenditure amounting to £7,770. With the exception of £1.500 to be expended on premises, this sum was entirely for the extension of mains and for the provision of the necessary apparatus for the utilisation of the current passing through the mains. The extensions were outside the compulsory area. This was all the evidence that was submitted, and the enquiry then closed.

Aberdeen.—At a meeting of the Gas Committee of Aberdeen Town Council proofs of the accounts of the Corporation gas and electric light for the year from July 31, 1894, to July 31, 1895, were submitted. The gas accounts showed a revenue of £76,821. 1s. 3d., and an expenditure of £63,944. 4s. 6d., leaving a balance to be carried to the net revenue account of £12,876. 16s. 9d. Annuities, interest, sinking fund, reserve and fire insurance fund, etc., had to be paid out of that, and a surplus of £398 more was absorbed, the result being to bring out a deficiency on the electric lighting department at December 31, 1894, of £217. 15s. 6d. With regard to the electric light, Mr. Cran had prepared a statement of accounts with the view of showing the Town Council how the department was working. The year, however, according to the Board of Trade regulations, finishes at December 31, and he will have to prepare another statement at that time. The department shows very good results. At the beginning of the year the Council reduced the price of the electric current from 7d. per unit to 6d. per unit, and up to July 31 the net deficit was only £109. 3s. 1d., which was considered to be very satisfactory. The accounts showed the revenue to be £2,975 (omitting shillings and pence), of which £2,704. 17s. 8d. was for sale of current per meter; £154. 12s. 8d. for public lighting, and £115 for rental of meters. On the expenditure side fuel cost £242; wages at generating station, £233; feu-duty and taxes, £125; salaries of engineers, £244. The balance carried to net revenue account was £1,815. 17s 10d., which, with £109 in addition, the loss for the year, is absorbed in paying interest on mortgage and other loans, £656; depreciation, £730; sinking fund, £538. A statement of the electricity generated shows that the quantity in Board of Trade units generated was 118,193; public lamps absorbed, 8,163; private consumers by meters absorbed 98,122; and the total quantity sold was 106,285. The quantity used in the works was 1,570, making the total quantity accounted for 10,338, and the number of public lamps was 10. In the course of the meeting of committee new rules, submitted by the electric engineer, for wiring houses were agreed to.

Nottingham.—The annual report of the Lighting Committee of the Corporation states that the committee have conducted the business of their department as usual during the year ending March 31 last. The following is the report of the lighting superintendent for the year: "Number of lamps March 31, 1894, 3,522; fixed since, 49; discontinued, 7; increase, 42—total number March 31, 1895, 3,564. Patent lanterns, March 31, 1894, 551; fixed since, 17; discontinued, 3; increase, 14—present number, March 31, 1895, 565. Electric lamps fixed since March 31, 1894, 8. (The patent lanterns and electric lamps were included in the above total of 3,564.) The position of 23 lamps had been

Digitized by Google

altered during the year. During the year eight columns had been broken and the cost of replacing them charged to the persons causing the damage. Four convictions had been obtained for damaging lamps and one for an assault on a lamplighter. The number of private lamps lighted and cleaned at the cost of the owners was 116. The staff on March 31, 1895 consisted of one superintendent and 42 lamplighters. Since the date of the last annual report the electric lighting station of the Corporation had been opened, and the committee thought the opportunity a good one to improve the lighting of the Great Market place. They therefore consulted Mr. Talbot, the electrical engineer, and under his advice and superintendence eight 4,000-c.p. electric lamps were erected, which were found to light the Market-place very efficiently and to be a great improvement on the lighting by gas. The committee had been able to remove permanently two of the large Bray lanterns formerly in use, and while the electric lights were burning the use of 18 more of the Bray lanterns was dispensed with, the value of the gas thus saved materially reducing the expense of the electric lights. The electric lamps were lighted on weekdays only, and the current was switched off at 11.15 p.m. At the Town Council meeting Mr. Pyatt drew attention to the lighting of the Market-place, and thought that as the electric lamps were lit at night it was a waste of money to keep the gas lamps alight. Alderman Ford remarked that the electric lights were extinguished at a quarter past eleven. The Sheriff asked why the electric lamps were not lit on Sunday night. He moved as an amendment that they be lit on Sunday nights mainly on the ground of convenience. Alderman Ford: They cost about 16s. an hour. For my part I think it very undesirable to have them alight on Sunday nights. Mr. Pyatt seconded the Sheriff's amendment. He thought that the town electric lamps should be lit for a certain period of Sunday night. He did not say for the whole night, but it was desirable that people assembling in the Market-place should have light. The Mayor: If the committee are prepared to do it all very well, but otherwise notice of motion must be given. Mr. Bentley: The lights might be turned out at 10 o'clock. Alderman Ford: If you will leave it to the committee they will undertake to consider the question.

Blackpool.—The *Blackpool Times* of September 4 has the following: Whatever views we may hold as to the decision of the Council to stop all further electrical extensions for a year—practically for two years—there can be no doubt as to the interest of the debate. Councillor Pearson was on his mettle, and a more able speech was never made in the Council, but the Blackpool Town Council seems quite incapable of coming to a decision on the merits of a case. There are so many conflicting interests, so many cross currents and by-questions, that it is impossible to get a straight vote in the Council on the merits of the question. Mr. Pearson's facts and figures are plain and clear, and place it beyond doubt that there is a great necessity for immediate development in our electrical supply. Stripping the question of all side issues, the simple fact is clearly established in Mr. Pearson's statement that the demand exceeds the supply. The decision of the Council practically means that unless we get rid of our largest customer—the Winter Gardens—we shall have no further supply of electricity for two years, at any rate for new customers. More than that, so extreme is the course taken as a result of carrying Councillor Ward's amendment, that we cannot even supply our present customers without risk of breakdown and disaster. Many people have fixed wires and other inside electrical appliances in their houses, in the expectation that they would soon be connected with the mains, and have their houses and other premises lit by electricity. They may take their wires down, and keep to gas, or return to oil and candles! The Electric Lighting Committee are at any rate relieved of responsibility, and may indulge in a Rip Van Winkle sleep for two years at least, unless the folly of yesterday's vote be discovered very soon. Just when our electricity has a chance of turning the corner, and by increasing the number of units supplied, for which there is ample demand, reducing the cost of production per unit, so making a profit for the ratepayers, the Council in a panic-fit upsets everything. It is not only two years that are lost to Blackpool's development in this particular, but more, for it will take a much longer time to win back the ground lost. Councillor Ward is a strong opponent, and he made the most of every point. But what does it all amount to? Simply that our electricity works are not yet making a clear profit, in the second year of working, though they are practically paying their way. He chooses for comparison with Blackpool, Newcastle, where the conditions are the most favourable in the kingdom for electrical production! Then he complains that the Winter Gardens and others get their light for 4d. a unit, when the town is charged 6d. But he forgets that these private consumers have to find, maintain, and keep in repair their own lamps. We are very glad to get these customers at the beginning of our electrical enterprise, and but for them there would have been but little hope of making the system pay at all. Councillor Ward's description of his own criticism as "mild" was correct, but he was quite straight, and the issue was clear enough, and so our electrical development is stifled indefinitely. We venture to predict that the Council will regret its decision. As to his attack on the tramway policy, the simple and complete answer is that, in spite of the cost he complains of, the tramways show a profit for the year up to date of £2,800. The committee have almost had to make a new line, while the figures he gave included the cost of new plant, dynamos, and cars, and this accounts probably for the apparent discrepancy between his estimate and that of the committee. Now that the opposition have succeeded in shelving Mr. Hammond, they have the responsibility of showing that they can organise electrical works themselves, and we shall see how they succeed.

Exeter.—A special meeting of the City and County Council has been held to consider the advisability of negotiating with the Exeter Electric Light Company for the acquisition of their undertaking. The Mayor presided. The Town Clerk said the meeting was convened under the direction of the Deputy-Mayor (Mr. E. J. Domville), acting in the absence of the Mayor. He had received a letter from Messrs. Roberts and Andrew, solicitors to the electric light company, who stated that they understood a meeting of the Council was to be called to consider this question. It was no doubt known that the company had been made an offer of £7,000 from a large London firm for their undertaking, and there was a syndicate of local gentlemen who would be prepared to give over £8,000. The critical condition of the company rendered it necessary that an immediate decision should be come to, and if the Council were willing to purchase for £10,000, the directors would recommend the proprietors to accept that amount. A memorial signed by all the principal tradesmen in High-street, Fore-street, and Queen-street had also been received in favour of the acquisition of the works by the Council. Mr. Domville said he had called the special meeting of the Council in response to a requisition he had received. Of course, that did not pledge the authority to take any action in the matter; it simply gave them an opportunity of considering the question and hearing what their legal position was. Under the provisional order, if the company became insolvent the Board of Trade could transfer its powers, and certain conditions were laid down under which the undertaking could be purchased. The matters involved required careful consideration. The less one said about the management of the company the better, but it was evident that misfortune had dogged its footsteps from the beginning, and the expenditure of a capital of £23,000 had not resulted in any profit to the shareholders. A large portion of that capital was now valueless to a purchaser, and what they had to think of was the present value of the undertaking, the possibility of the company carrying out its obligations, and the further demands that would be likely to be made on any purchaser in extending the works. They had also to consider whether it would be wise for them to wait the 17, 18, or 19 years that must expire before they could acquire the works under the provisional order, or whether they should seize the opportunity which now offered itself of purchasing them. He thought it would be best to refer the whole subject to a special committee, and he moved that that should be done. Mr. Ward seconded. After some discussion Mr. Domville withdrew his motion, and Mr. W. Wreford moved a resolution declaring it to be expedient that the control and supply of the electric light in the city should be in the hands of the Council. By doing this they would only be reaffirming what they did three or four years ago, when they promoted a provisional order in opposition to one applied for by the present company. Mr. E. C. Penny seconded. He had always held that such an important element of civilisation as light should be in the hands of the municipality. He thought the city made a great mistake in not purchasing the gasworks when they had the opportunity some years ago, and if they let this chance slip they would be making another mistake. Mr. Jarman supported the motion. In reply to Mr. Fulford, the Town Clerk said in this case it would not be necessary to take a poll of the ratepayers. The motion was carried, 29 voting for and none against. Mr. Wreford then proposed that it was desirable to enter into negotiations with the electric light company with a view to acquiring their undertaking. The company had come to the conclusion to transfer their shares and debentures to a London firm for £7,000 and they had no reason assigned yet why the Council should go further and offer £10,000. But that was a matter of detail which could be threshed out in committee. Was that a favourable opportunity for purchasing? Under the provisional order they could at the end of 26 years take over the works by paying the value of the plant and an equivalent to the previous five years' profits, and only at the end of 42 years could they acquire the property without paying anything for profits. They had now a chance of getting the undertaking on much better terms, and he believed they could effect the purchase without inflicting any pecuniary burden on the ratepayers. Mr. E. C. Perry seconded and after some remarks from Alderman Houlditch, who said he hoped the proceedings would result in the streets being lighted by electricity at an early date, the motion was carried. The further consideration of the matter was referred to Council in committee, with power to appoint a special committee to decide points of detail.

Cheltenham.—A correspondent writes: "The interior of the Public Library presented an unusually animated appearance at 9 p.m. on Monday, and though the hour was a somewhat late one for a public ceremony, none more suitable for the important business in hand, which was no less than the inauguration of the electric light in the building. To make way for the electric light all the gas fittings had been bundled out 'neck and crop,' and during the time that the workmen had been engaged in putting in the fittings for the new illuminant the library had been lighted by something even more primitive than gas—to wit, oil, which somewhat feebly illuminated the place when the guests of the Public Library Committee assembled there on Monday evening. The installation cost about £112, and was carried out by Messrs. Marshall and Co. from specifications prepared by Mr. Kilgour, resident electrician. One and a quarter mile of wire was used, and altogether 141 incandescent lamps (exclusive of the electrolier) were placed in the building, varying from 8 c.p. to 32 c.p., and giving a total illuminating power equal to that of 2,712 candles. The lamps are distributed in the principal rooms as follow: news-room, 52 lamps, 688 c.p.; reference library and book-store,

Digitized by Google

36 lamps, 912 c.p.; lending library and book store, 29 lamps, 624 c.p.; corridor, eight lamps, 120 c.p.; basement, 16 lamps, 208 c.p. The main switch in the basement controls the whole of the installation, and thence the mains are carried first to a distributing board in the basement, and then to the main distributing board on the ground floor, where the current is divided into 11 circuits. In the news-room there are four circuits—one for centre lights, one for tables, one for brackets, and one for newspaper stands—so that each set of lights may be used separately as required. In the lending library there is a circuit for counter and indicators, but in addition there are six circuits for the book-stores at the back. The reference library has three circuits, two for the tables and one for the book-store. In the public part of the reference library each lamp has a separate switch. In the lending as well as in the reference library switches are placed over each alcove, so that when economy so dictates the light may be switched off where it is no longer needed. The corridor and stock-room have also a circuit to themselves. The electrolier, presented by the Baron de Ferrieres, which forms a striking ornament of the vestibule, has a separate circuit, lighting nine 32-c.p. lamps, equal to 288 c.p. It was designed and executed by the contractors in wrought iron, with copper ornaments. The position of the lights was arranged by Mr. Kilgour, resident electrician, and by Mr. Jones, chief librarian." At the last Town Council meeting the fire brigade superintendent recommended that the existing fire bell be removed, that each member of the brigade be connected with an electric call bell, and that his private rooms should be connected by telephone direct with the fire station or through the exchange. It was resolved that the recommendations of the superintendent be left to the sub-committee to consider. The electrical engineer reported to the Lighting Committee that about 50 arc lamps would be required to light the Promenade to the Gordon lamp, Clarence-street to the Great Western Railway Station, Ambrose street and High-street, from Ambrose-street to the Royal Hotel, replacing 311 gas-burners, and averaging 30 to 40 yards apart in the Promenade and about 70 to 80 in the remaining streets The estimated capital costs were: alternating-current system £3,100, rectified-current system £5,070, assuming all the lamps were supported on pillars If the arc lamps in the Promenade were supported on centre arches, the additional cost per arc so supported would be £20 to £30; and with 30 all-night arcs and 30 arcs switched off at midnight the total annual costs would be; alternating-current system £957, or about £19. 10s. per arc; rectified-current system £1.075, or about £21. 10s. per arc. It was resolved that the report be approved, and that the committee propose to act on the lines indicated by it, and to adopt the alternating-current system for street-lighting. It was also resolved that the electrical engineer be authorised to engage a clerk at a salary not exceeding 12s. a week. Mr. Williams, secretary of the Cheltenham Theatre Company, complained of insufficient light in Ormond-place and Regent-street. It was resolved to place additional lamps in Eldorado-road, Cranham-road, and Whaddon-lane, and to consider the feasibility of lighting the town clock by electric light. It was also resolved to pay the poor-rate assessment of £320 on the electric station under protest. It was resolved to obtain transformers at the estimated cost of £123, to lay a cable in High-street at a cost of £180, to obtain from Messrs. Belliss and Co. an engine capable of driving direct a 100-kilowatt alternator for £729. 17s., and to do minor works.

Hampstead.—In his annual report on the work of the Vestry for the year ended March 25, Mr. A. P. Johnson, the vestry clerk, says, under the heading "Electric Lighting": The foundation-stone of the central electric lighting station, situate in the stone-yard, Lithos-road, was formally laid by Mr. J. Thwaites, chairman of the Lighting Committee, on May 23, 1894. The station, plant, and mains were completed and in working order by the end of September, and the electric current was first supplied to consumers on October 1, when, at the opening ceremony, held in the evening of that day, the current was switched on by Mr. R Hackworth. There has been some slight trouble with the public arc lamps in the Finchley-road, but those difficulties which arose have been speedily grappled with, and at the present time the public lighting of the Finchley-road, from Arkwright-road to Boundary-road—*i.e.*, the end of the parish—is a complete success. The private lighting has worked very smoothly from the commencement of the supply on October 1. At that date there were 13 consumers, with an equivalent of 1,648 8-c.p. lamps connected to the mains. At Christmas the number of 8-c.p. lamps installed had risen to 4,000, and on March 25 to 6 500 Since the period covered by this report the total number of consumers has risen to 116, with an equivalent of 11,879 8-c p. lamps connected. This will show the large strides the electricity department has made since the station was opened. The Vestry are, at the present time, carrying out very large extensions, notably the High-road, Kilburn, and West-end-lane. The applications for current from intending consumers are of such a character that the Lighting Committee are even now seriously considering the advisability of increasing their plant at the station. The Vestry have had under their consideration the public lighting of the High-road, Kilburn, with arc lamps. The Willesden Urban Council, who have part jurisdiction of that road, were approached on the subject, and the Vestry submitted the terms upon which they would undertake the lighting. These terms were not acceptable to the Willesden Urban Council, and so the Vestry have reluctantly been compelled to let the matter stand in abeyance. The mains for the supply of electricity to private consumers are laid in the following roads—viz.: Arkwright-road, Belsize-avenue, Belsize-grove, Belsize-lane (from Daleham-gardens to Fitzjohn's-avenue), Belsize-park, Belsize-park-gardens, Buckland-crescent, Daleham-gardens, Eton-avenue, Finchley-road (from Boundary-road to Langland-gardens). Fitzjohn's avenue, Frognal (from Finchley-road to Arkwright-road), Gayton-road (from High-street to No. 11), Haverstock-hill (from Rosslyn-hill to Belsize-grove), Heath-street (from Church-lane to High-street), High-street, Lindfield-gardens, Lithos-road, Lyndhurst-gardens, Lyndhurst-road, Maresfield-gardens, Netherhall-gardens, Nutley-terrace, Rosslyn-hill, Strathray-gardens, Wedderburn-road, Windsor-terrace (from Lyndhurst-road to Springmead). Extensions of the mains have also been ordered on the following roads, and are being carried out as quickly as possible—viz.: Belsize-square (east and west sides), Branch-hill, Ellerdale-road (from Prince Arthur-road to Arkwright-road), England-lane, Finchley-road (from Parsifal-road to Burrard-road), Fortune-green-lane (from West end-green to Parsifal-road), Frognal-rise, Haverstock-hill (from Belsize-grove to Eton-road), High-road, Kilburn (from southern boundary to Maygrove-road), Holly-hill, Inglewood-road, Lancaster-place, Parsifal-road, Prince Arthur-road, West-end-lane (from Gascony-avenue to West-end-green), West Heath-road (from Branch-hill to Redington-road). The Vestry are prepared to consider applications for the supply of the current in any of the other roads of the parish. The price charged for electricity during the night service—*i.e.*, from sunset to midnight—is 6d. per unit, and during light and day services, ranging from midnight to sunset (for which purpose special arrangements must be made), 4d. per unit. The bills of private consumers amounting to £25 and upwards per annum (for current only) will be subject to the following reductions—viz.:

Annual bill.	Reduction.
£25	3 per cent.
50	5 ,,
100	10 ,,
250	15 ,,
500 and over	20 ,,

The rebate will be made annually on the Christmas quarter's account. It is intended that a separate report shall be issued at Christmas, 1895, on the working of the station from the opening up to that time, and together with that report will be published the accounts of the electric lighting undertaking.

Stafford.—A correspondent writes: In a very few days upwards of a score of business places and dwelling-houses in Stafford will be lighted by the electric light from the current supplied from the Corporation electric station. The engines and boilers have been fixed and tried, the dynamos are in place, and will be run next week under the direction of a representative of the Electric Construction Corportion. The only missing link literally is the switchboard, by which the connection will be made from the dynamos to the cables. Of cables there have now been laid some 9,000 yards, if we include the service branches. Speaking broadly, the main cable runs the whole length of the main street of the borough from the newly-made spacious entrance to the electric station, near Messrs. Bostock's factory, as far as the new Baptist Chapel in course of erection at the entrance of the Lichfield-road, which itself is to be lighted by electricity. This main cable is tapped laterally, first to supply the county infirmary, which is to be lighted by electricity, then a branch is carried down Salter-street for the Vine Hotel. A cable also encircles the Market-square, branches down Market street, also by St. Martin's-place, and down Martin-street to the County Council Buildings, where the Corporation will have large consumers of their new product. Another branch cable stretches up St. Mary's-gate to the County Council Technical Instruction Buildings, supplying on the way the Conservative Club, which has already been wired, and is ready to take the new illuminant. Another feeder runs down Tipping-street to supply consumers there, and then the main, as we have said, continues along the principal thoroughfares. It is not proposed at present to undertake street-lighting, but as an experiment it is intended to erect one or two arc lamps in the Gaol-square when the electric station is opened on September 25. The present plant at the station, as now on the verge of completion, is capable of supplying 6,000 8-c p. lamps, all in use at one time. The present demand, as enumerated above, is for upwards of 2,000 such lamps. The system adopted here is the low-pressure continuous-current, with accumulators so that the engine power may be utilised during the day and the electricity stored in the accumulators and utilised at night. Thus the engines can be used during the day for the night supply. It will be satisfactory to every ratepayer in the borough to realise that the electric station is one that can almost be cited as a model for excellence in design and construction and the efficiency of the plant. The boiler and engine houses themselves are almost models of what such places should be The site of the buildings, which cover an area of 130ft. by 70ft, was a waste unsightly space between the gasworks and Messrs. Bostock's factory, and a wide and spacious approach has been secured from Foregate-street to the departmental office of the electric station. The head office of the combined gas and electricity departments of the Corporation, under the charge of the energetic manager, Mr. Bell, is, of course, at the existing gas offices. The three large boilers have been under steam some time now, and with the engines work admirably and smoothly. They are being covered with Leroy and Co.'s non-conducting composition to prevent the radiation of the heat from their large surface and from the steam-pipes, and the result is that the large and roomy house, 56ft. by 40ft., and proportionately high, is comparatively cool. Each boiler is 28ft. long, with a diameter of 7ft. 6in., and each is fitted with a patented breeze furnace, by which they can be made to consume the waste unsaleable fine coke. A jet of steam can be blown along a pipe under the furnace bars, developing a high forced draught, and great heat is main-

Digitized by Google

tained from this waste fuel. The necessary slack is brought by a siding to the furnace doors, and the water runs from the river by a pipe to a cistern hard by, whence it is pumped to a purifying apparatus and fed to the boilers. The engine-house, where are the three engines and dynamos, is a fine building on a higher level under the same general roof of the whole block. It is built internally of white glazed brick, and there is a travelling crane capable of lifting 12 tons, by which the heavy parts of the engines can be lifted and dropped in their places. The flywheels, which run partly above the floor and partly below, are 12ft. 1in. in diameter, and deeply grooved with seven grooves to take the 1¼in. cotton ropes that will drive the pulleys on the dynamos. These ropes are being supplied through Mr. Jas. Macrea, engineer, of Stafford. The engines are compound, with high-pressure cylinders of 11in. diameter and low-pressure cylinders of 19in. diameter and with a 26in. stroke. They run very smoothly. They are fitted with Korting's jet condensers and Proell's automatic expansion valve gears. Each of them can be worked up to 150 h.p., but as a rule they will be run at their most economical load of 120 h.p. The iron floor plating necessary here in the floor along the ends of the engines, together with the exhaust mains, has been supplied by Messrs. Bagnall and Co, Limited. The engines standing on a higher floor than the level of the boiler-house, and being raised on massive brick buttresses, there is thus a kind of half cellar underneath them, and the dynamos and any part of the fixtures can be viewed at work from below as well as above. There is a roomy space of two-fifths of the whole area of the engine-house still available for fixing two other engines should any very great demand for the supply of electricity for lighting purposes in time arise, but the present installation will meet all requirements for some time to come. The boilers have been supplied by Messrs. Hick, Hargreaves, and Co., the engines by Messrs. Marshall, of Gainsborough, the dynamos by the Electric Construction Corporation, of Wolverhampton, and the cables by Messrs. Siemens and Co, of London. The Corporation put the foundation in themselves, and the building has been erected by Mr. Lovatt, of Wolverhampton The three boilers are of 1,000 h.p., and the three dynamos of 66 kilowatts each. The present installation, it is stated, is sufficient for any probable house demand and for the electric lighting of the main street. The switchboard, when erected next week, will separate an adjacent fitting shop from the engine-house. Above here, on the north side, and approached by steps from the new entrance from Foregate-street, is the battery-room, where are 112 accumulator cells, supplied by the Chloride Electrical Storage Syndicate. These have to be maintained in working order by that company for three years, under their contract with the Corporation. Here the electricity generated during the day will be conserved for use at night, when the engines are stopped. Adjacent, on the other side of the landing, is the office of the electric works, where the head electrician and his assistant will be in attendance, and where fittings and electric lighting appliances can be seen and ordered. On the occasion of the laying of the memorial stone in the electric station in October last year by the then Mayor (Mr. G. Wormal), Alderman W. H. Peach, the chairman of the Gas and Electric Lighting Committee, expressed the hope that the whole work would be carried out without any accident to the lives or limbs of those employed upon them. This hope has been realised, and that it has been so is not the least satisfactory feature of an undertaking that has apparently been so admirably carried out with credit to all concerned. The committee, in view of the completion of the works for the provision of electric light to the town, have appointed a sub-committee to make all necessary arrangements for a public opening ceremony of the works on September 25.

PROVISIONAL PATENTS, 1895.

AUGUST 26.

16008. **An improved telephonic instrument designed for use on poorly-insulated lines, such as the existing wires of an ordinary wire fence.** Gustaf Dillberg and Parnell Rabbidge, 40, Chancery-lane, London. (Complete specification.)

16019. **Improvements in connection with incandescent electric lamps and their holders and fittings.** James Yate Johnson, 47, Lincoln's-inn-fields, London. (Alfred Swan, United States.)

AUGUST 27.

16022. **An improved form of cell for primary or secondary electric batteries.** Edward Burnet and Frederick Foy Smith, the Grammar School, Park-lane, near Wigan.

16042. **A compound electrical testing switch.** Howard Dudley Norman, 69, Brunswick-place, Brighton.

16077. **Improvements in electromagnetic tools.** William Phillips Thompson, 31, High Holborn, London. (Abraham George Fonda, United States.) (Complete specification.)

AUGUST 28.

16173. **A switch formed as a handle in which electric circuit is completed by the automatic fall of a piece of solid metal contained within the handle.** Charles Solomon Newman, 13, Pembridge-crescent, London.

AUGUST 29.

16218. **Improvements in electrical fire and burglar alarms.** John Ronald Shearer, 28, Southampton-buildings, Chancery-lane, London.

16247. **Improvements in or connected with electric cables or conductors.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

16248. **Improvements in electric transformers and dynamo armatures.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

AUGUST 30.

16275. **Improvements in instruments for making electrical and magnetic measurements.** James Finlayson, 62, St. Vincent-street, Glasgow.

16287. **Improvements in dynamo-electric machines and motors.** Louis Hallé, 18, Buckingham-street, Strand, London. (Complete specification.)

AUGUST 31.

16350. **Improvements in or relating to electric batteries.** Alfred Julius Boult, 323, High Holborn, London. (E. A. Wunderlich, Germany.)

SPECIFICATIONS PUBLISHED.

1894.

14988. **Electrolytic cells.** Wise. (Solvay.)

15219 **Telephonic, etc., lines.** Müller.

16162. **Secondary batteries.** Engl.

17066. **Electric cables.** De Ferranti.

17737. **Electric cables.** Nisbett.

18809. **Secondary batteries.** King.

21045. **Dynamo-electric machines.** Hutin and Leblanc.

24615. **Lightning arresters.** Blackmore and Carlin.

1895.

4873. **Electrical insulating materials.** T. P. and G. H. Wiggins.

12469. **Electric railway vehicles.** Müller.

12772. **Electric circuits.** Rowand.

12836. **Electric cut-outs.** Dorman and Smith.

12953. **Chloride of lead.** Chloride Electrical Storage Syndicate, Limited, and Rhodin.

12954. **Secondary batteries.** Chloride Electrical Storage Syndicate, Limited, and Grindle.

NOTES.

The Telephone in Japan.—It is said that Tokio has six telephonic exchanges, Osaka three, and Yokohama and Kobe two each, and that the cost to subscribers is about £9 a year.

The Electric Light in Ceylon.—There is apparently a great demand for the electric light in Colombo for both private and public purposes, and the local firm of electrical engineers is said to have its books full of orders. "When," asks an Indian correspondent, "is Calcutta going to begin in earnest?"

The Electric Furnace.—A new claimant for priority in the application of the electric furnace to the working of refractory metals and to the production of calcium carbide has, it appears, come upon the scene in the person of Dr. Torres, a French chemist. Dr. Torres claims that he put his ideas in this direction into practice months before either Moissan or Willson did.

Electric Traction in Italy.—The Italian Society for the Promotion of Light Railway Construction (L'Unione delle ferrovie italiane di interesse locale) has, *Elettricità* of September 8 says, drawn up a memorial to the Minister of Public Works praying for a modification of the existing laws governing the building and working of secondary railways with a view to the application of electric traction.

A Telegraph Office on the Atlantic.—The Commercial Cable Company has established, in connection with the international yacht race, a telegraph office on the Atlantic Ocean. It has stationed its steamer, the "Mackay-Bennett," at the point where the "Defender" and the "Valkyrie" begin their contests, and has connected the vessel with Great Britain and France by its main ocean cables.

Telephony and Telegraphy in Spain.—*El Telegrafista Español* announces the opening for public use by the Compañia Telefónica Interurbana of its telephone station in Bilbao, which has now direct communication with San Sebastian, Vittoria, and Durango. The same journal reports the publication of "El Catálogo general de las Estaciones Telegráficas de la Península Española," being a register of telegraph offices in Spain.

The Electric Light in Russia.—The municipal authorities of Warsaw have elaborated a project for the grant of a concession to electrically light the whole of their city. There are required 233 1,000-c.p. arc lamps and 5,140 incandescent lamps. Contractors have to deposit 125,000 roubles upon announcing their resolution to tender for the installation, while a successful offer involves the deposit of a further sum of 125,000 roubles. The concession will be valid for a period of 35 years.

Light Railways.—The Bishop of Chester appeals for State aid for the purpose of constructing a light railway in Cardiganshire. The line would, he says, develop the resources of the district by finding for its farm produce and for the fish which is plentiful in Cardigan Bay a ready market among the swarming industrial population of Glamorganshire and Monmouthshire; would bring back coal, lime, and other supplies, and would open up and render accessible some delightful bathing places on the coast.

Glasgow - London Telegraphy. — The Glasgow Chamber of Commerce at their last meeting authorised the Home Affairs Committee to petition the Postmaster-General regarding the time taken in telegraphing between Glasgow and London. The members had provided themselves with batches of telegrams which showed that the average time occupied in despatching messages over the Post Office wires between the two cities was 30 minutes and the longest 65 minutes. It is stated that the Glasgow Royal Exchange is framing a similar petition.

A New Game.—Philadelphia youngsters have devised a delightful game which they call "Trolley Car." It is played by from two to twenty juveniles, all but one of whom sprawl on the pavement, while this selected one trundles a baby carriage over them. In Chicago a rather different view of the matter is taken. The following so-called epigram from the *Daily Tribune* is there very popular:

"As to the trolley wires,
It has been found
Cheaper to put the people
Under the ground."

The Electric Light in China.—Haiphong, we are told, has now electric light in its streets, like Hongkong, and has also its "Chinaman who ceaselessly climbs to the top of the lamp-posts with a hammer and chisel in one hand and a coil of wire in the other." But the Haiphong acrobatic wireman, we are further informed, is not so nimble as his colleague in Hongkong, who never seems to miss his footing. The French colony has only had the electric light for a few weeks, but an accident has already occurred, a man falling from the top of a standard with fatal results.

Canadian Canals and Electricity.—St. Mary's Canal, the new Canadian waterway connecting Lakes Superior and Huron, has just been opened for traffic. The lock measures 900ft. by 60ft., and is 20ft. deep. The gates and valves are worked by electricity. The construction of the canal, which has cost £750,000, gives Canada an independent waterway from the head of Lake Superior to the ocean. The American engineers engaged in cutting the canal on the Michigan side of the river telegraphed their congratulations to the Government on the successful inauguration of this magnificent undertaking.

Telegraphy in Argentina.—Construction work on the telegraph line from Bahia-Blanca to Mar del Plata is so far advanced that Mr. Segovia, the engineer, has his tents now pitched on the farms near Necochea. The work is for the account of the National Government, and the telegraphic stations will be Monte Hermoso, La Sirena, El Cristiano, Necochea, and Mar del Plata, while there will be a branch line from El Cristiano to Tres Arropos, with an intermediate station at San Jorge. The service was, it appears, so badly wanted that the neighbouring estancieros patriotically subscribed upwards of 9,000dol. towards the cost.

Horses v. Electricity.—An enthusiastic correspondent writes: "Horse haulage will soon be a thing of the past in Glasgow. A strong sub committee of the Corporation Tramway Committee has been appointed to enquire into the application of mechanical or electric motors to tramway cars, and there can be no doubt that the result of its investigations will be that the horse will be superseded. Perhaps when that day comes there will be a realisation of the dream of the city artisan being whirled away out into the suburbs, when the city will be given over entirely to commerce, and everybody will stay in pretty little cottages in the country." Details will be found in our "Business Notes."

The Electric Light in Argentina.—The Mayor of Buenos Ayres has forwarded to the City Council a proposal for the establishment of three electric light stations in Calles 60 A, Cordoba, and Caseros, for lighting the streets. The cost of the installation is estimated at 346,929dol. gold and 125,280dol. national money. The Public

Digitized by Google

Works Committee has, however, disapproved of the scheme, and proposed that the director of public lighting be sent to Europe and the United States in order to investigate and study the systems of electric street-lighting in vogue in the various cities there. The Committee of Interpretation, on the other hand, is of opinion that the Mayor's proposition should be confirmed.

Electricity and Mining. — The latest indication that the connection between the mining industry and electricity is gradually drawing closer is the fact that the Westralia Mining Company, Limited, has acquired the concession for the exclusive right of furnishing electric light to the municipality of Coolgardie for the term of 21 years. This concession it has, in turn, sold to the Westralian Electric Lighting and Supply Company, Limited, which has been formed with a capital of £80,000, in £1 shares, of which £35,000 are working capital. It is possible that the dreary mushroom town of Coolgardie, where so-called fresh water costs about a shilling a gallon, may have the electric light before the railway touches the "municipality."

Charterhouse Science and Art Schools and Literary Institute.—The winter session of this institution, one of the largest science and art schools in the United Kingdom, will commence on Saturday, September 28, under the presidency of the Rev. Henry Swann, M.A. During the late session upwards of 1,200 students, mostly elementary teachers, availed themselves of the privileges afforded by this institution, and of this number 682 presented themselves for examination, and were successful in obtaining a large number of certificates awarded by the Science and Art Department of South Kensington. Several students prepared for the Lond. B.Sc. (Int.) examination. Instruction of a practical character is given in most of the sciences at a very nominal fee, whilst in art at an equally low rate students under the direction of competent instructors can be advanced in their studies.

Electric Traction in Germany.—Some further particulars are published in the *Elektrotechnischer Anzeiger* of September 8 of the tour which a deputation from the Berlin Town Council made in order to study the method of street locomotion adopted in various towns. Visits were paid to Dresden, Dessau, Hagen, Frankfurt-a.-M., Strassburg, Paris, London, Liverpool, Glasgow, Edinburgh, Rotterdam, The Hague, Amsterdam, and Brussels. The deputation state that underground railways, like those in Paris, London, Glasgow, and Liverpool, could not very well be built in Berlin, owing to the floating-sand strata, and they recommend that experiments be made, as far as possible on existing horse lines, with the overhead conductor, the Klette (Dresden)—the lead—accumulator, the gas motor, and the Serpollet (steam) system. The first electric tramway in Berlin was, by the way, opened to public traffic on Tuesday.

"Strassenbahnwagenuntergestelle." — A short time since the English and American technical Press waxed funny over this compound German word, and now the *Elektrotechnische Zeitschrift* has its say on the matter. "Some time ago," it remarks, "English and American technical journals gave a humorous explanation of the word 'Strassenbahnwagenuntergestelle,' which corresponds to the English word 'truck.' These two words are in a certain sense characteristic of the two languages: a German combines words with each other and obtains a word which, though long, can be understood by one who has never heard it before; the Englishman creates new words for new things, or he uses well-known words with a new meaning." But to say that the German monstrosity corresponds to "truck" is scarcely correct. It is literally "street railway car underframe," which cannot really be compressed into anything less than "street-car underframe" or "tramcar underframe."

Signs of the Times.—The advance which is being made towards the universal adoption of electricity as an illuminant is nowhere, a correspondent writes, more noticeable than in Staffordshire. It is not to be wondered at that the county town, with its central situation and numerous advantages over places of greater extent and population, should be anxious to keep well abreast of the times in this respect, and, in point of fact, the Corporation electricity supply will be ready for use by the end of the month—about the same time that the new light will be introduced at Walsall. A more remarkable portent of the times is that the small country town of Cheadle, and the still less known district of Alsager, on the northern borders of this county, should have at present under consideration the adoption of the electric light; while the Rugeley Urban District Council have signified their intention of taking into consideration the lighting of the streets by electricity.

"Hyde Park at Night."—One of the discussers of this unsavoury subject in the daily Press—Mr. E. J. Watherston—makes a practical suggestion. He says: "The state of this park after dark is known to all who have the misfortune to make a short cut across it after nightfall. The reason is simple: it is not lighted. Applications have been made over and over again to the proper authorities, but, although we are spending imperially one hundred millions per annum, there is no money forthcoming to light up Hyde Park. And yet it is open to the public until, I believe, 12.30 a.m. The electric light well placed and well distributed would alter the conditions of the place half an hour after lighting up, and for ever. Let us hope that, now public attention and indignation have been aroused, her Majesty's Office of Works, which has done so much for the improvement of all the Royal parks, may immediately, even without waiting for a supplementary vote in Supply, give the necessary instructions for lighting Hyde Park in such a way as to prevent any recurrence of the evil complained of." We can only interject, in sympathy with the correspondent's views, *Fiat lux!*

Electrical Potentials in a Liquid Conductor in Uniform Movement.—Mr. G. Gouré de Villemontée, in *Comptes Rendus*, deals with this subject. Mercury, and solutions of zinc, copper, and nickel sulphates containing 10 grams of the salt per litre, were caused to move through insulated horizontal or vertical glass tubes of uniform bore, the diameter being 3mm. for mercury and 8mm. for the saline solutions, and observations were made with a view to detect differences of potential between two points in the liquid. The capillary electrometer used would indicate a difference of 0·00015 volt. The electrodes consisted of platinum wires, the ends of which were coated with an electrolytic deposit of the metal contained in the saline solution. Sometimes both electrodes were in the path of the moving liquid, sometimes one was in the moving liquid and the other in the reservoir. The rate of movement of the liquids was 33·5mm. per second in the horizontal tubes and 155·3mm. to 323mm. in the vertical tubes. The results show that the uniform movement of a liquid conductor along wide insulated glass tubes of uniform section produces no appreciable difference of potential between two points of the liquid within the limits of velocity specified.

Horseless Carriages.—In view of the exhibition which he proposes to hold during next month if the horseless carriages which are being specially constructed to his order in Paris be then completed, Sir David Salomons

Digitized by Google

has published some remarks in favour of the employment of steam, petroleum, and electric carriages or wagons by farmers and others, as against light railways, which he believes would not pay; or road trains, which would soon render the roads useless for any other traffic. In his opinion the Acts of Parliament regulating the use of locomotives on roads do not forbid the employment of self-contained and self-propelling carriages, which did not exist when the Act was framed, but the ordinary statutes make all necessary provision for the regulation of such locomotion to avoid danger or nuisance. Sir David speaks in praise of the French system of "voitures automobiles," and adds that a Frenchman looks at him with incredulity when told that there is no similar system in England. It is a disgrace, Sir David says, that a great engineering nation, which was the pioneer of railways, should be the only spot in Europe where such a state of things exists. The question has never been carried to the higher courts as to whether such vehicles may or may not be used, but simply rests on a magistrate's decision that a bicycle is a traction engine if propelled by other than animal power!

Personal.—In order to show their appreciation of the able manner in which Alderman Lennard, as chairman, has for a number of years presided over their deliberations, and more especially of his services in connection with the electric light installation, the members of the Gas and Electric Lighting Committee of the Corporation of Leicester decided to make him a presentation in the form of an album containing the photographs of the members of the committee, and to include Mrs. Lennard in the tribute. It was intended to make this presentation at the time of the celebration of the installation of the electric light, but some delay took place in obtaining the photographs, and thus the matter was postponed. The album being now complete, Alderman and Mrs. Lennard were invited to a tea party in the recreation and reading room of the gasworks on Thursday last week, in order that they might receive it. On the outside of the cover were the initials of the worthy alderman and his wife, and the flyleaf bore the following illuminated inscription: "This album was presented to Alderman Lennard, chairman of the Corporation Electric Lighting Committee, by his colleagues, as a souvenir of the inauguration of the Leicester Corporation electric lighting works, and also as an expression of the high appreciation of his valuable services in connection with the department over which he has presided for the past six and a half years." This was signed by the whole of the members of the committee and the engineer, Mr. A. Colson.

The Electrical Effects of the Last Storm.—Mr. M. Williams, of Hyde Park Court, Albert-gate, S.W., seems to be nothing if he is not tempestuously daring. He writes: As witnessed from the top of this lofty, prominent building, the local electrical and atmospheric effects of the thunderstorm of September 7 were exceptionally striking. On account of its situation and structure this building may readily be expected to lend itself to manifestations of electrical discharge under the exceptional atmospheric conditions that prevailed. The north side directly faces the great open space of Hyde Park, and the various blocks are capped by high pointed towers, which rise to a height of some 130ft., far above all surrounding buildings. There is also a large mass of exposed metalwork, such as pipes, metal roofing, and a network of large iron flues, which are connected to some 80 chimneys, being used for artificial draught and operated by an electric fan fixed on the roof. In addition to this, an iron spiral outdoor staircase runs up nearly the whole of the building. Lightning-conductors formed of a network of copper strip are well connected to earth, and also to the water-pipes and metalwork on the roof. The storm seemed to approach with great rapidity, and the top of the building for fully half-an-hour was enveloped in a curious mist, or rather a luminous vibrating glow, having much the same effect as that produced in Mr. Tesla's beautiful experiments with high-tension alternating currents of high frequency at the Royal Institution. The turrets and other portions of the roof forming the sky-line seemed to give forth streams of light, while at rapid intervals bunches of thin riband-like lightning darted from the luminous mist to various exposed points of the roof, and nearly always apparently in an upward direction. During this period there were no loud thunder claps, but a succession of crisp trembling detonations as from a Wimshurst machine. The only sensation I experienced whilst standing either on the metal roofing or iron staircase was a pleasant exhilarating sensation accompanied by the distinct smell of ozone, as in the Tesla experiments. As the storm passed over the usual heavy flashes and thunder claps commenced. I observed two exceptionally heavy lightning discharges in a southerly direction, which appeared likely to have produced local damage. The panorama of London illuminated under the above conditions was beautiful in the extreme.

Lightning-Conductors on Ships.—Mr. C. Tomlinson, F.R.S., says that in 1866 he described a method of receiving the discharge of a Leyden jar on a plate of crown glass. "Supposing," he adds, "such a discharge to represent in miniature a lightning discharge, we have a tree-like figure with trunk, branches, and spray, and in some cases bifurcations and even trifurcations. About this time lightning-conductors were not in favour either on land or sea. When the new buildings of the Cholmeley School, Highgate, were being erected, the then headmaster, Dr. Dyne, consulted me as to the desirability of a lightning-conductor, and asked me to see the architect on the subject. That gentleman assured me that he had never erected a lightning-conductor, and did not know how; that his profession regarded conductors as attracting lightning to the place instead of repelling it. A similar opinion was held at the Admiralty. Snow Harris had strenuously recommended his metallic conductors for ships, and had abundantly proved what important losses had occurred through their absence. He had obtained permission to erect his conductors on ten ships destined for foreign service, and in one of them a flagstaff had been put up above the conductors, and was consequently shattered by a lightning stroke, but no further damage was done. This trifling accident seemed to justify the order for the removal of the conductors from each ship on its return home. But at Devonport a bifurcated discharge occurred which had most singular results. Sir John Rennie was employed by the Admiralty to erect two victualling houses at Devonport. Each was furnished with a granite chimney rising 60ft. above the roof. One of these was furnished with a lightning-conductor; but before the other was erected Rennie called on Snow Harris with the indignant complaint that the charge for lightning-conductors had been struck out of the estimates. Harris said, 'Well, never mind, Nature will avenge us!' Never was prophecy more amply fulfilled. A bifurcated stroke of lightning fell on the two victualling houses; the protected building suffered no injury, the unprotected chimney was torn open, with other damage to the building, to the admiration of the British Association, which met at Plymouth that same year—namely, 1841. This fortunate bifurcation at once made lightning-conductors popular. Harris's admirable arrangements for ships were in due time adopted, to the immense advantage

Digitized by Google

of the Navy. Harris was knighted, received a Civil List pension of £200 a year, and lastly the House of Commons, on the motion of Lord Palmerston, made Harris a grant of £6,000 for his invention, the noble mover stating that he never made a similar motion with greater pleasure." Since the Navy has been thus protected, Mr. Tomlinson does not remember hearing of the slightest damage being done to any of her Majesty's ships.

The Pacific Cable.—Some particulars as to the progress made by American promoters of a Pacific cable are to hand. Colonel Z. S. Spalding, the projector of the new cable to connect the Hawaiian islands and to place Honolulu and San Francisco in direct telegraphic communication, has appeared before the trustees of the Chamber of Commerce of 'Frisco to explain to them in detail what he has thus far accomplished, and consult them as to the steps now to be taken to secure the co-operation of the United States in the undertaking of which he is the promoter. Mr. Sanford Ballard Dole, it appears, signed the agreement with Colonel Spalding on August 12. By it the latter is granted an exclusive franchise for 20 years from November 1, 1895, "to construct and land upon the shores of the Hawaiian group, a submarine electric telegraph cable, or cables, to or from any point or points on the North American continent, or any island or islands contiguous thereto." It is, however, stipulated that the first cable have its terminus in San Francisco, and it is for the maintenance of this that the subsidy will be paid by the Hawaiian Government for 20 years. The amount of the subsidy is to be 40,000dol. a year from the date of the establishment of telegraphic communication between Honolulu and San Francisco and between Honolulu and the islands of Hawaii, Maui, Molokai, and Kauai. The agreement is hedged with further conditions, among them being one that the work of construction shall commence on or before May 1, 1897, and another that telegraphic communication shall be established not later than November, 1898. Yet another is that the Government of the United States shall join in the undertaking "by the grant of substantial assistance to the contractor." If this assistance were not granted, or should the contractor fail to comply with the conditions of the agreement, then the Hawaiian Government, it is stated, will have the right of cancelling the contract 60 days after service upon the banking house of Bishop and Co. at Honolulu of a notice of its intention so to do. A free right of way across all Government lands and exemption from duty on all materials and from taxes and port charges is granted to the contractor for 20 years, as well as the privilege of condemning and appropriating such property or rights of way as may be necessary for the operation of the cable. If the Government should desire to assume control and ownership of the interisland lines at the end of one year after the completion of the system, it reserves the right to do so on payment of the cash cost of the land, stations, lines, and equipments free of all encumbrances and liens for bonds or interest on bonds. The contract, moreover, specifies that Press messages shall be carried at a rate not to exceed half of the regular rates charged, and Government messages up to the cost of the annual subsidy must be carried free. The promoter is, finally, required to give bonds to the amount of 25,000dol. for the faithful fulfilment of his contract.

Electric Traction in India.—The Madras electric tramway question is still a fertile theme of discussion in the Indian technical Press. "Generally speaking," says a work on "Electric Traction," "it may be laid down that the underground conduit system requires for its successful working (1) sufficient traffic to warrant the extra expenditure involved in the construction and maintenance of a conduit; (2) an ample depth in the street for a conduit of sufficient capacity to prevent flooding; and (3) good and efficient drainage." In adopting the conduit system in Madras the last two considerations, a correspondent observes, were evidently lost sight of, or it was thought they could be surmounted. However this may be, the overhead is about to be substituted for the present conduit system, and, from all accounts, it is a much more simple system of traction than the conduit, while in initial cost and maintenance it is appreciably cheaper. Another advantage in the overhead system is that the conductors, insulators, etc., are all above ground, and a glance is sufficient to detect anything wrong, while repairs can be made easily and without any delay. In America, where the overhead system has generally been adopted, there are over 1,000 miles of electric tramways laid down, representing a capital of £50,000,000. The machinery now used in Madras is of the very latest description; and is, for the present, under the management and supervision of Mr. Gadsby, a Whitworth scholar and an electrical engineer of considerable attainments. The power-house and workshops at Egmore are worth a visit. Two dynamos are working—one only is used at a time—alternately from 6 a.m. to 8.30 p.m. Each dynamo is built for 240 amperes at a pressure of 500 volts, and is capable of driving 20 cars at a speed of 15 miles an hour; but for the present only a pressure of 350 volts is required, and an average speed of about eight miles an hour is maintained. The engine-house contains two high-pressure engines fitted with Corliss's valve gear, and wood is used as fuel, 4½ tons being necessary daily for the seven cars at work. The local tramway cars began working in the early part of May, and although only seven cars have been running on one section of the line from the Custom House to Egmore, the earnings are fairly remunerative, and the trustees of the debenture-holders consider that they have no reason to be dissatisfied. The section from the Custom House to Egmore, being a double line, represents a distance of 5½ miles. There are two more sections under construction, about three miles and 1¼ mile long respectively. Accurate information as to the earnings, the number of passengers carried, etc., up to date is not available at present, but the trustees think that the three sections will cost, and can be worked at, little more than one. There is, the correspondent adds, room for improvement in regard to lessening the noise made by the cars, in respect of the uniforms of the conductors, ticket examiners, and drivers, and especially in the direction of making passengers more comfortable. An improved style of car is, however, being designed. As soon as sections 2 and 3 are equipped on the overhead system, the present conduit system in force on No. 1 section will be abandoned for the overhead system.

Electric Street-Lighting.—Mr. George Cutter, in a paper read before the North-Western Electrical Association at Chicago, said that in considering a question like that of lighting streets, alleys, and public squares, we should first define the results to be produced by the lighting system. It appears quite simple to define the theoretically perfect lighting, but it is not as easy to decide which system gives results nearest to the theoretical; local conditions affect this question more or less. A general uniform illumination of mild intensity, such as that of a dark cloudy day or possibly that of a clear night with a full moon, is the theoretical condition to be produced by artificial lighting. This is especially the case after bedtime. But for proper results we must produce a brilliant illumination of the business centre until bedtime, and for the sake of econ omy we must then change the down-town illumina-

Digitized by Google

tion to the same mild intensity that serves for the residence districts earlier in the evening. There is one important factor in street-lighting which might modify our practice in regard to the best general illumination. It is the police duty of the light in preventing crime and in facilitating the capture of criminals. But even for this duty a uniform illumination of mild intensity is likely to prove best, because the eye which is adjusted to a bright light cannot distinguish objects in a dull light. There are various points to be considered when we come to the practical side of the question and try to determine what system will give the best approach to the theoretical results with the fewest practical objections. Among these points I might mention a few of the most important: (1) We should consider the means of distribution to produce the nearest to our theoretical conditions—that is, we should aim to procure a uniformity of light, even of mild intensity, in preference to a few extra bright spots with intervening dark spots. An exception can be made, as before indicated, for the business section before bedtime, a brilliant illumination of this section in the early part of the night changing to correspond with the rest of the city for the rest of the night. (2) Reliability of service of the lighting system, since it loses its effectiveness either as a safeguard as a path-finder, or unless it is perfectly reliable. (3) Steadiness of illumination is another point closely connected in importance to the one just mentioned, and in the same line of thought—viz., that of avoiding contrasts in illumination either in different localities or at different times. Determining the last two points brings us to the fourth: necessary skill of all labour and ease of procuring same, the employment of home talent to the greatest extent possible being usually advisable. If the installation and operation of our plant requires special skill, then absence of this skill might cause bad service, or even total cessation of light. Then there is the durability of the apparatus, together with ease and economy of replacing used-up parts. In considering this we must look out for both the probability of permanency of the supply of duplicate parts, and the amount of attention to keep all in good working shape. After careful judging of the closely related points thus far enumerated, we can well give attention to the sixth: efficiency of conversion from coal pile to light. My only comment on this point is that I place it second in importance to that of general uniform illumination, as high efficiency can well be set aside for the other more desirable feature of uniformity. Considerations of this point of efficiency leads to the seventh—total operating expenses—the importance of which depends almost entirely upon local conditions; as also the eighth point: cost of necessary plant for producing the light. This leads to the ninth: appearance of fixtures on streets and squares, and on this point more attention should be given than is the usual practice. A large share of the opposition to overhead wiring would never have been raised if it had not been for the bungling work which is so common.

Double Swing-Bridge Operated by Electrical Power.—Among drawbridges that have recently been constructed, the one which spans the Cuyahoga River at Columbus-street, Cleveland, Ohio, has attracted an unusual amount of attention on account of several novel features which have been introduced into its design and method of operation. It was built to replace an old swing-bridge with a centre pier, which was a serious obstruction to traffic on account of a sharp bend in the river at this point and the narrow passage allowed for vessels on each side of the pier. It was also necessary to build the abutment farther back at one end to make way for the tracks of a railroad company, which owned the right of way. To meet all the requirements in the most satisfactory manner and at the least expense, the city engineer, Mr. Walter P. Rice, designed a double swing-bridge. Briefly described, this bridge consists of two independent swing spans, mounted upon piers on each side of the channel of the river, thus leaving a clear space for navigation between the protections of the piers of 121ft. These spans are identical in construction, being 139½ft. long, and forming, when the bridge is closed, a continuous roadway of 279ft. from abutment to abutment and 20ft. wide between wheel guards, with a sidewalk 6ft. in width on each side. The bridge is built on a grade, the south end being 8ft. higher than the north. This is accomplished by a difference in the heights of the bearings for the loading beams, thus allowing the drum to turn in a horizontal plane. The structure is of special interest from the fact that it is operated by electricity, and all auxiliary motions are accomplished by compressed air, the compressor being driven by an electric motor. There being two spans, the bridge is really operated by two entirely independent electric plants, duplicates of each other. The current is brought to the bridge by separate lines from two different street railway circuits, and is brought to the junction-box at the top of the south pier by lead-covered cables protected by an iron conduit. From the junction-box the mains are run through a duct leading from the outside of the masonry of the pier to the hollow centre casting about which the drum turns, and are connected with stranded conductors which lead to the floor of the bridge above, whence the cables continue to the main switch in the operating-house. All the wires used about the bridge are lead covered with the exception of the connection between the fixed centre casting and the flooring of the bridge which turns. This of necessity must be flexible, that it may not be injured by the motion of the bridge in moving through an angle of 90deg. in either direction and back. For protection from moisture and mechanical injury, the flexible conductors are enclosed in heavy rubber tubing. A double-throw switch in the operator's house enables current to be taken for the bridge from either power circuit. Duplicate iron-armoured submarine cables connect with the operating-house on the opposite span, and double-throw switches allow the spare cable to be thrown in if any trouble develops in the one in use. The drum of each span is revolved by means of the usual rack and pinion. A 25-h.p. Westinghouse waterproof multipolar railway motor is attached to the horizontal driving shaft. The controllers used were designed especially for this plant, and are exceedingly simple and compact, the resistance being located beneath the floor. No reversing switch is required, a forward or backward motion of the lever giving a corresponding motion to the bridge. This controller gives the bridge a noticeably smooth start, and there is an entire absence of the arcing common in 500 volt work. Each span is provided with an automatic switch which opens the circuit in case, through carelessness or from any other cause, the bridge swings beyond 90deg. In the south operating-house is an air-compressor, which is driven by a 5-h.p. slow-speed Westinghouse motor, and which pumps into the receivers beneath the floor of the bridge. These receivers are also connected with a similar set on the other span by means of a heavy lead pipe laid under the river. The connection between the fixed and movable parts of the bridge is made by means of flexible steam hose. The compressed air is used for operating the locks at the shore end of each span and the plungers and apron at the centre. The bridge is described and illustrated in detail by our Chicago contemporary, *The Western Electrician*, of August 24.

THE BRITISH ASSOCIATION AT IPSWICH.

The sixty-fifth annual meeting of the British Association for the Advancement of Science commenced at Ipswich on Wednesday, under the presidency of Sir Douglas Galton, who, in the absence of the retiring president, the Marquis of Salisbury, was introduced to the meeting by Lord Kelvin. Up to Wednesday evening nearly 1,200 tickets had been issued. An unfortunate incident marked the reading of the presidential address. The Public Hall was lighted by gas, and the room grew very hot shortly after Sir Douglas rose. He appeared to be affected by the vitiated atmosphere from the first, and about the middle of his speech he broke done, and Sir J. Evans continued the reading of the address. Sir Douglas, however, sufficiently recovered to acknowledge the vote of thanks accorded to him for his address, which was as follows:

Presidential Address

BY SIR DOUGLAS GALTON, K.C.B., D.C.L., F.R.S.

My first duty is to convey to you, Mr. Mayor, and to the inhabitants of Ipswich, the thanks of the British Association for your hospitable invitation to hold our sixty-fifth meeting in your ancient town, and thus to recall the agreeable memories of the similar favour which your predecessors conferred on the association 44 years ago.

In the next place, I feel it my duty to say a few words on the great loss which science has recently sustained—the death of the Right Hon. Thomas Henry Huxley. It is unnecessary for me to enlarge, in the presence of so many to whom his personality was known, upon his charm in social and domestic life; but upon the debt which the association owes to him for the assistance which he rendered in the promotion of science I cannot well be silent. Huxley was pre-eminently qualified to assist in sweeping away the obstruction by dogmatic authority, which in the early days of the association fettered progress in certain branches of science. For, whilst he was an eminent leader in biological research, his intellectual power, his original and intrepid mind, his vigorous and masculine English, made him a writer who explained the deepest subject with transparent clearness. And as a speaker his lucid and forcible style was adorned with ample and effective illustration in the lecture-room; and his energy and wealth of argument in a more public arena largely helped to win the battle of evolution, and to secure for us the right to discuss questions of religion and science without fear and without favour. It may, I think, interest you to learn that Huxley first made the acquaintance of Tyndall at the meeting of the association held in this town in 1851.

About 46 years ago I first began to attend the meetings of the British Association, and I was elected one of your general secretaries about 25 years ago. It is not unfitting, therefore, that I should recall to your minds the conditions under which science was pursued at the formation of the association, as well as the very remarkable position which the association has occupied in relation to science in this country. Between the end of the sixteenth century and the early part of the present century several societies had been created to develop various branches of science. Some of these societies were established in London, and others in important provincial centres. In 1831, in the absence of railways, communication between different parts of the country was slow and difficult. Science was therefore localised; and, in addition to the universities in England, Scotland, and Ireland, the towns of Birmingham, Manchester, Plymouth, and York each maintained an important nucleus of scientific research.

Origin of the British Association.

Under these social conditions the British Association was founded in September, 1831. The general idea of its formation was derived from a migratory society which had been previously formed in Germany; but whilst the German society met for the special occasion on which it was summoned, and then dissolved, the basis of the British Association was continuity. The objects of the founders of the British Association were enunciated in their earliest rules to be: "To give a stronger impulse and a more systematic direction to scientific enquiry; to promote the intercourse of those who cultivated science in different parts of the British Empire with one another, and with foreign philosophers; to obtain a more general attention to the objects of science, and a removal of any disadvantages of a public kind which impede its progress." Thus the British Association for the Advancement of Science based its utility upon the opportunity it afforded for combination.

The first meeting of the association was held at York with 353 members. As an evidence of the want which the association supplied, it may be mentioned that at the second meeting, which was held at Oxford, the number of members was 435. The third meeting, at Cambridge, numbered over 900 members, and at the meeting at Edinburgh in 1834 there were present 1,298 members. At its third meeting, which was held at Cambridge in 1833, the association, through the influence it had already acquired, induced the Government to grant a sum of £500 for the reduction of the astronomical observations of Baily; and at the same meeting the General Committee commenced to appropriate to scientific research the surplus from the subscriptions of its members. The committees on each branch of science were desired "to select definite and important objects of science, which they may think most fit to be advanced by an application of the funds of the society, either in compensation for labour, or in defraying the expense of apparatus, or otherwise, stating their reasons for their selection, and, when they may think proper, designating individuals to undertake the desired investigations." The several proposals were submitted to the Committee of Recommendations, whose approval was necessary before they could be passed by the General Committee. The regulations then laid down still guide the association in the distribution of its grants. At that early meeting the association was enabled to apply £600 to these objects.

I have always wondered at the foresight of the framers of the constitution of the British Association, the most remarkable feature of which is the lightness of the tie which holds it together. It is not bound by any complex central organisation. It consists of a federation of sections, whose youth and energy are yearly renewed by a succession of presidents and vice-presidents, whilst in each section some continuity of action is secured by the less movable secretaries. The governing body is the General Committee, the members of which are selected for their scientific work; but their controlling power is tempered by the law that all changes of rules, or of constitution, should be submitted to and receive the approval of the Committee of Recommendations. This committee may be described as an ideal second chamber. It consists of the most experienced members of the association. The administration of the association in the interval between annual meetings is carried on by the council, an executive body, whose duty it is to complete the work of the annual meeting (*a*) by the publication of its proceedings; (*b*) by giving effect to resolutions passed by the General Committee; (*c*) it also appoints the Local Committee and organises the *personnel* of each section for the next meeting. I believe that one of the secrets of the long-continued success and vitality of the British Association lies in this purely democratic constitution, combined with the compulsory careful consideration which must be given to suggested organic changes.

The association is now in the sixty-fifth year of its existence. In its origin it invited the philosophical societies dispersed throughout Great Britain to unite in a co-operative union. Within recent years it has endeavoured to consolidate that union. At the present time almost all important local scientific societies scattered throughout the county, some 66 in number, are in correspondence with the association. Their delegates hold annual conferences at our meetings. The association has thus extended the sphere of its action: its places the members of the local societies engaged in scientific work in relation with each other, and brings them into co-operation with members of the association and with others engaged in original investigations, and the papers which the individual societies publish annually are catalogued in our report. Thus by degrees a national catalogue will be formed of the scientific work of these societies. The association has, moreover, shown that its scope is coterminous with the British empire by holding one of its annual meetings at Montreal, and we are likely soon to hold a meeting in Toronto.

Conditions of Certain Sciences at the Formation of the British Association.

The association at its first meeting began its work by initiating a series of reports upon the then condition of the several sciences. A rapid glance at some of these reports will not only show the enormous strides which have been made since 1831 in the investigation of facts to elucidate the laws of Nature, but it may afford a slight insight into the impediments offered to the progress of investigation by the mental condition of the community, which had been for so long satisfied to accept assumptions without undergoing the labour of testing their truth by ascertaining the real facts. This habit of mind may be illustrated by two instances selected from the early reports made to the association. The first is afforded by the report made in 1832, by Mr. Lubbock, on "Tides." This was a subject necessarily of importance to England as a dominant power at sea. But in England records of the tides had only recently been commenced at the dockyards of Woolwich, Sheerness, Portsmouth, and Plymouth, on the request of the Royal Society, and no information had been collected upon the tides on the coasts of Scotland and Ireland. The British Association may feel pride in the fact that within three years of its inception—viz., by 1834—it had induced the Corporation of Liverpool

Digitized by Google

to establish two tide gauges, and the Government to undertake tidal observations at 500 stations on the coasts of Britain.

Another cognate instance is exemplified by a paper read at the second meeting, in 1832, upon the "State of Naval Architecture in Great Britain." The author contrasts the extreme perfection of the carpentry of the internal fittings of the vessels with the remarkable deficiency of mathematical theory in the adjustment of the external form of vessels, and suggests the benefit of the application of refined analysis to the various practical problems which ought to interest shipbuilders—problems of capacity, of displacement, of stowage, of velocity, of pitching and rolling, of masting, of the effects of sails and of the resistance of fluids; and, moreover, suggests that large-scale experiments should be made by Government, to afford the necessary data of calculation. Indeed, when we consider how completely the whole habit of mind of the populations of the Western world has been changed, since the beginning of the century, from willing acceptance of authority as a rule of life to a universal spirit of enquiry and experimental investigation, is it not probable that this rapid change has arisen from society having been stirred to its foundations by the causes and consequences of the French Revolution? One of the earliest practical results of this awakening in France was the conviction that the basis of scientific research lay in the accuracy of the standards by which observations could be compared; and the following principles were laid down as a basis for their measurements of length, weight, and capacity—viz., (1) that the unit of linear measure applied to matter in its three forms of extension—viz., length, breadth, and thickness—should be the standard of measures of length, surfaee, and solidity; (2) that the cubic contents of the linear measure in decimetres of pure water at the temperature of its greatest density should furnish at once the standard weight and the measure of capacity.* The metric system did not come into full operation in France till 1840, and it is now adopted by all countries on the continent of Europe except Russia.

The standards of length which were accessible in Great Britain at the formation of the association were the parliamentary standard yard lodged in the Houses of Parliament (which was destroyed in 1834 in the fire which burned the Houses of Parliament), the Royal Astronomical Society's standard, and the 10ft. bar of the Ordnance Survey. The first two were assumed to afford exact measurements at a given temperature. The Ordnance bar was formed of two bars on the principle of a compensating pendulum, and afforded measurements independent of temperature. Standard bars were also disseminated throughout the country, in possession of the corporations of various towns. The British Association early recognised the importance of uniformity in the record of scientific facts, as well as the necessity for an easy method of comparing standards and for verifying differences between instruments and apparatus required by various observers pursuing similar lines of investigation. At its meeting at Edinburgh in 1834 it caused a comparison to be made between the standard bar at Aberdeen, constructed by Troughton, and the standard of the Royal Astronomical Society, and reported that the scale "was exceedingly well finished; it was about 1-500th of an inch shorter than the 5ft. of the Royal Astronomical Society's scale, but it was evident that a great number of minute, yet important, circumstances have hitherto been neglected in the formation of such scales, without an attention to which they cannot be expected to accord with that degree of accuracy which the present state of science demands." Subsequently, at the meeting at Newcastle in 1863, the association appointed a committee to report on the best means of providing for a uniformity of weights and measures with reference to the interests of science. This committee recommended the metric decimal system—a recommendation which has been endorsed by a committee of the House of Commons in the last session of Parliament.

British instrument-makers had been long conspicuous for accuracy of workmanship. Indeed, in the eighteenth century practical astronomy had been mainly in the hands of British observers; for although the mathematicians of France and other countries on the continent of Europe were occupying the foremost place in mathematical investigation, means of astronomical observation had been furnished almost exclusively by English artisans. The sectors, quadrants, and circles of Ramsden, Bird, and Cary were inimitable by Continental workmen. But the accuracy of the mathematical-instrument maker had not penetrated into the engineer's workshop. And the foundation of the British Association was coincident with a rapid development of mechanical appliances. At that time a good workman had done well if the shaft he was turning, or the cylinder he was boring, "was right to the 1-32nd of an inch." This was, in fact, a degree of accuracy as fine as the eye could usually distinguish. Few mechanics had any distinct knowledge of the method to be pursued for obtaining accuracy; nor, indeed, had practical men sufficiently appreciated either the immense importance or the comparative facility of its acquisition. The accuracy of workmanship essential to this development of mechanical progress required very precise measurements of length, to which reference could be easily made. No such standards were then available for the workshops. But a little before 1830 a young workman named Joseph Whitworth realised that the basis of accuracy in machinery was the making of a true plane. The idea occurred to him that this could only be secured by making three independent plane surfaces; if each of these would lift the other, they must be planes, and they must be true. The true plane rendered possible a degree of accuracy beyond the wildest dreams of his contemporaries in the construction of the lathe and the planing machine, which are used in the manufacture of all tools. His next step was to introduce an exact system of measurement, generally applicable in the workshop. Whitworth felt that the eye was altogether inadequate to secure this, and appealed to the sense of touch for affording a means of comparison. If two plugs be made to fit into a round hole, they may differ in size by a quantity imperceptible to the eye, or to any ordinary process of measurement, but in fitting them into the hole the difference between the larger and the smaller is felt immediately by the greater ease with which the smaller one fits. In this way a child can tell which is the larger of two cylinders differing in thickness by no more than 1-5000th of an inch. Standard gauges, consisting of hollow cylinders with plugs to fit, but differing in diameter by the 1-1000th or the 1-10000th of an inch were given to his workmen, with the result that a degree of accuracy inconceivable to the ordinary mind became the rule of the shop. To render the construction of accurate gauges possible Whitworth devised his measuring machine, in which the movement was effected by a screw; by this means the distance between two true planes might be measured to the one-millionth of an inch. These advances in precision of measurement have enabled the degree of accuracy, which was formerly limited to the mathematical-instrument maker, to become the common property of every machine shop. And not only is the latest form of steam-engine, in the accuracy of its workmanship, little behind the chronometer of the early part of the century, but the accuracy in the construction of experimental apparatus which has thus been introduced has rendered possible recent advances in many lines of research.

Lord Kelvin said in his presidential address at Edinburgh, "Nearly all the grandest discoveries of science have been but the rewards of accurate measurement and patient, long-continued labour in the sifting of numerical results." The discovery of argon, for which Lord Rayleigh and Prof. Ramsay have been awarded the Hodgkin prize by the Smithsonian Institution, affords a remarkable illustration of the truth of this remark. Indeed, the provision of accurate standards not only of length, but of weight, capacity, temperature, force, and energy are amongst the foundations of scientific investigation. In 1842 the British Association obtained the opportunity of extending its usefulness in this direction. In that year the Government gave up the Royal Observatory at Kew, and offered it to the Royal Society, who declined it. But the British Association accepted the charge. Their first object was to continue Sabine's valuable observations upon the vibrations of a pendulum in various gases, and to promote pendulum observations in various parts of the world. They subsequently extended it into an observatory for comparing and verifying the various instruments which recent discoveries in physical science had suggested for continuous meteorological and magnetic observations, for observations and experiments on atmospheric electricity, and for the study of solar physics. This new departure afforded a means for ascertaining the advantages and disadvantages of the several varieties of scientific instruments, as well as for standardising and testing instruments, not only for instrument-makers, but especially for observers by whom simultaneous observations were then being carried on in different parts of the world, and also for training observers proceeding abroad on scientific expeditions. Its special object was to promote original research, and expenditure was not to be incurred on apparatus merely intended to exhibit the necessary consequences of known laws.

The rapid strides in electrical science had attracted attention to the measurement of electrical resistances, and in 1859 the British Association appointed a special committee to devise a standard. The standard of resistance proposed by that committee became the generally accepted standard, until the requirements of that advancing science led to the adoption of an international standard. In 1866 the Meteorological Department of the Board of Trade entered into close relations with the Kew Observatory. And in 1871 Mr. Gassiot transferred £10,000 upon trust to the Royal Society for the maintenance of the Kew Observatory for the purpose of assisting in carrying on magnetical, meteorological, and other physical observations. The British Association thereupon, after having maintained this observatory for nearly 30 years at a total expenditure of about £12,000, handed the observatory over to the Royal Society.

The *Transactions* of the British Association are a catalogue

* The litre is the volume of a kilogramme of pure water at its maximum density, and is slightly less than the litre was intended to be—viz., one cubic decimetre. The weight of a cubic decimetre of pure water is 1 000013 kilogrammes.

Digitized by Google

of its efforts in every branch of science, both to promote experimental research and to facilitate the application to the practical uses of life. But probably the marvellous development in science which has accompanied the life-history of the association will be best appreciated by a brief allusion to the condition of some of the branches of science in 1831 as compared with their present state.

Geological and Geographical Science.

Geology.—At the foundation of the association, geology was assuming a prominent position in science. The main features of English geology had been illustrated as far back as 1821, and, among the founders of the British Association, Murchison and Phillips, Buckland, Sedgwick and Conybeare, Lyell, and De la Beche, were occupied in investigating the data necessary for perfecting a geological chronology by the detailed observations of the various British deposits, and by their co-relation with the Continental strata. They were thus preparing the way for those large generalisations which have raised geology to the rank of an inductive science. In 1831 the Ordnance maps published for the southern counties had enabled the Government to recognise the importance of a geological survey by the appointment of Mr. De la Beche to affix geological colours to the maps of Devonshire and portions of Somerset, Dorset, and Cornwall; and in 1835 Lyell, Buckland, and Sedgwick induced the Government to establish the Geological Survey Department, not only for promoting geological science, but on account of its practical bearing on agriculture, mining, the making of roads, railways, and canals, and on other branches of national industry.

Geography.—The Ordnance survey appears to have had its origin in a proposal of the French Government to make a joint measurement of an arc of the meridian. This proposal fell through at the outbreak of the Revolution, but the measurement of the base for that object was taken as a foundation for a national survey. In 1831, however, the Ordnance Survey had only published the 1in. map for the southern portion of England, and the great triangulation of the kingdom was still incomplete. In 1834 the British Association urged upon the Government that the advancement of various branches of science was greatly retarded by the want of an accurate map of the whole of the British Isles, and that consequently the engineer and the meteorologist, the agriculturist and the geologist, were each fettered in their scientific investigations by the absence of those accurate data which now lie ready to his hand for the measurement of length, of surface, and of altitude. Yet the first decade of the British Association was coincident with a considerable development of geographical research. The association was persistent in pressing on the Government the scientific importance of sending the expedition of Ross to the Antarctic and of Franklin to the Arctic regions. We may trust that we are approaching a solution of the geography of the North Pole; but the Antarctic regions still present a field for the researches of the meteorologist, the geologist, the biologist, and the magnetic observer, which the recent voyage of M. Borchgrevink leads us to hope may not long remain unexplored. In the some decade the question of an alternative route to India by means of a communication between the Mediterranean and the Persian Gulf was also receiving attention, and in 1835 the Government employed Colonel Chesney to make a survey of the Euphrates valley in order to ascertain whether that river would enable a practicable route to be formed from Iskanderoon, or Tripoli, opposite Cyprus, to the Persian Gulf. His valuable surveys are not, however, on a sufficiently extensive scale to enable an opinion to be formed as whether a navigable waterway through Asia Minor is physically practicable, or whether the cost of establishing it might not be prohibitive. The advances of Russia in Central Asia have made it imperative to provide an easy, rapid, and alternative line of communication with our Eastern possessions, so as not to be dependent upon the Suez Canal in time of war. If a navigation cannot be established, a railway between the Mediterranean and the Persian Gulf has been shown by the recent investigations of Messrs. Hawkshaw and Hayter, following on those of others, to be perfectly practicable and easy of accomplishment; such an undertaking would not only be of strategical value, but it is believed it would be commercially remunerative. Speke and Grant brought before the association at its meeting at Newcastle, in 1863, their solution of the mystery of the Nile basin, which had puzzled geographers from the days of Herodotus, and the efforts of Livingstone and Stanley and others have opened out to us the interior of Africa. I cannot refrain here from expressing the deep regret which geologists and geographers, and indeed all who are interested in the progress of discovery, feel at the recent death of Joseph Thomson. His extensive, accurate, and trustworthy observations added much to our knowledge of Africa, and by his premature death we have lost one of its most competent explorers.

Chemical, Astronomical, and Physical Science.

Chemistry.—The report made to the association on the state of the chemical sciences in 1832 says that the efforts of investigators were then being directed to determining with accuracy the true nature of the substances which compose the various products of the organic and inorganic kingdoms, and the exact ratios by weight which the different constituents of these substances bear to each other. But since that day the science of chemistry has far extended its boundaries. The barrier has vanished which was supposed to separate the products of living organisms from the substances of which minerals consist, or which could be formed in the laboratory. The number of distinct carbon compounds obtainable from organisms has greatly increased, but it is small when compared with the number of such compounds which have been artificially formed. The methods of analysis have been perfected. The physical, and especially the optical, properties of the various forms of matter have been closely studied, and many fruitful generalisations have been made. The form in which these generalisations would now be stated may probably change, some, perhaps, by the overthrow or disuse of an ingenious guess at Nature's workings, but more by that change which is the ordinary growth of science—namely, inclusion in some simpler and more general view. In these advances the chemist has called the spectroscope to his aid. Indeed, the existence of the British Association has been practically coterminous with the comparatively newly developed science of spectrum analysis, for though Newton,* Wollaston, Fraunhofer, and Fox Talbot had worked at the subject long ago, it was not till Kirchhoff and Bunsen set a seal on the prior labours of Stokes, Angström, and Balfour Stewart that the spectra of terrestrial elements have been mapped out and grouped; that by its help new elements have been discovered, and that the idea has been suggested that the various orders of spectra of the same element are due to the existence of the element in different molecular form—allotropic or otherwise—at different temperatures. But great as have been the advances of terrestrial chemistry through its assistance, the most stupendous advance which we owe to the spectroscope lies in the celestial direction.

Astronomy.—In the earlier part of this century, whilst the sidereal universe was accessible to investigators, many problems outside the solar system seemed to be unapproachable. At the third meeting of the association, at Cambridge, in 1833, Dr. Whewell said that astronomy is not only the queen of science, but the only perfect science, which was "in so elevated a state of flourishing maturity that all that remained was to determine with the extreme of accuracy the consequences of its rules by the profoundest combinations of mathematics; the magnitude of its data by the minutest scrupulousness of observation." But in the previous year—viz., 1832—Airy, in his report to the association on the progress of astronomy, had pointed out that the observations of the planet Uranus could not be united in one elliptic orbit—a remark which turned the attention of Adams to the discovery of Neptune. In his report on the position of optical science in 1832, Brewster suggested that with the assistance of adequate instruments "it would be possible to study the action of the elements of material bodies upon rays of artificial light, and thereby to discover the analogies between their affinities and those which produce the fixed lines in the spectra of the stars; and thus to study the effects of the combustions which light up the suns of other systems." This idea has now been realised. All the stars which shine brightly enough to impress an image of the spectrum upon a photographic plate have been classified on a chemical basis. The close connection between stars and nebulæ has been demonstrated; and while, on the one hand, the modern science of thermodynamics has shown that the hypothesis of Kant and Laplace on stellar formation is no long tenable, enquiry has indicated that the true explanation of stellar evolution is to be found in the gradual condensation of meteoritic particles, thus justifying the suggestions put forward long ago by Lord Kelvin and Prof. Tait. We now know that the spectra of many of the terrestrial elements in the chromosphere of the sun differ from those familiar to us in our laboratories. We begin to glean the fact that the chromospheric spectra are similar to those indicated by the absorption going on in the hottest stars, and Lockyer has not hesitated to affirm that these facts would indicate that in those localities we are in the presence of the actions of temperatures sufficiently high to break up our chemical elements into finer forms. Other students of these phenomena may not agree in this view, and possibly the discrepancies may be due to default in our terrestrial chemistry. Still, I would recall to you that Dr. Carpenter, in his presidential address at Brighton in 1872, almost censured the speculations of Frankland and Lockyer in 1868 for attributing a certain bright line in the spectrum of solar prominences

* Joannes Marcus Marci, of Kronland, in Bohemia, was the only predecessor of Newton who had any knowledge of the formation of a spectrum by a prism. He not only observed that the coloured rays diverged as they left the prism, but that a coloured ray did not change in colour after transmission through a prism. His book, "Thaumantias. Liber de Arcu Cœlesti Deque Colorum Apparentium Natura," Prag, 1648, was, however, not known to Newton, and had no influence upon future discoveries.

Digitized by Google

(which was not identifiable with that of any known terrestrial source of light) to a hypothetical new substance which they proposed to call "helium," because "it had not received that verification which, in the case of Crookes's search for thallium, was afforded by the actual discovery of the new metal." Ramsay has now shown that this gas is present in dense minerals on earth; but we have now also learned from Lockyer that it and other associated gases are not only found with hydrogen in the solar chromosphere, but that these gases with hydrogen form a large percentage of the atmospheric constituents of some of the hottest stars in the heavens. The spectroscope has also made us acquainted with the motions and even the velocities of those distant orbs which make up the sidereal universe. It has enabled us to determine that many stars, single to the eye, are really double, and many of the conditions of these strange systems have been revealed. The rate at which matter is moving in solar cyclones and winds is now familiar to us. And I may also add that quite recently this wonderful instrument has enabled Prof. Keeler to verify Clerk-Maxwell's theory that the rings of Saturn consist of a marvellous company of separate moons—as it were, a cohort of courtiers revolving round their queen—with velocities proportioned to their distances from the planet.

(To be continued.)

The following paper was read in Section G:

The Subject of Light Railways as an Assistance to Agriculture.

BY MAJOR-GENERAL WEBBER, C.B, R.E.

A new impetus was given to the extension of light railways in the United Kingdom, as my hearers are aware, by the President of the Board of Trade under the late Government, who last December summoned a meeting of representatives of various bodies and interests, and selected from its members a committee to consider the subject. One of the results was that the then Government included in the Queen's speech, read at the opening of the parliamentary session of 1895, a reference to the subject, as a possible amelioration of agricultural depression. From the first moment, even before the committee was formed, a considerable divergence of opinion as to the best way of promoting the objects of the conference was evident. I believe we are indebted for this revival of the subject of extension of light railways in this country to the electrical industry, which, following on the vast extension of electric traction in the United States, had for some time been engaged not only in demonstrating its possibilities, but also in showing that electric traction was being practically discouraged under the stringent Board of Trade rules, which had been originally framed in the interests of public safety for the control of railway construction and working, and which had only been filtered in the course of their application to tramways worked with steam and cable traction. There seems to be a natural tendency in the minds of a population, accustomed to seeing draught animals in front of all road vehicles, to apprehend some special danger from a vehicle which is propelled by some unusual means, travelling on, or by, a public road. Steam traction, on road tramways, as existing in crowded thoroughfares at Leeds and Birmingham, may, on the other hand, be cited to show how the public may become accustomed to the proximity of a steam locomotive, an object which railways have taught them to regard as best out of the way and running between two fences.

Besides such examples as those above referred to, a few cable traction lines, such as those at Edinburgh, and two or three electric lines, such as that in Staffordshire, had been established. The public here had but few examples of light lines not worked with horses, which are not practically railways in the sense that they are not fenced in. What are known as "light railways" in Ireland are not in the category of the subject with which I desire to deal. From the first they were destined, by the preponderance of railway opinion which was on the commission of enquiry into the subject, and which made the recommendation under which Parliament provided the guarantee of the cost of their construction, to be railways in the ordinary acceptation of the term. They are practically branch feeders of the Irish railway system, and are no doubt well adapted to the wants of the districts into which they have penetrated, but they do not afford much guidance to the working out of such a problem as we have met to consider. In the same category I include the line well known to you all—viz., from Halesworth to Southwold. This line was originally projected to be laid at the side of the Ipswich and Lowestoft turnpike road starting from Darsham, but when its design was radically changed it ceased to afford a practical example, either from the engineering or the commercial point of view, of the kind of transport to which I seek to direct your attention. At the same time Ireland was early in the field with its steam road tramways between Dublin and Lucan and between Cork and Blarney, both of which have been successful.

I do not wish to cast any invidious reflection on railway engineers and managers, when I ask you to realise that their training and lifework is likely to unfit them for dealing with our subject, and that those of them only who in considering it have cast themselves adrift from their traditions can impartially study the question. The material they have handled all their lives, the traffic they have managed, the capital expenditure with which they deal, and the rules and regulations under which they work, with the necessary organisation and administration involved, is as different as the highly-appointed four-horse mail coach was from the old packman's beast of burthen. It was therefore particularly unfortunate when, in selecting the committee to which I have already referred, the strongest men on it were taken from the representatives of the great railway companies, and these chiefly from the least practical side of that representation. I don't know whether I am right in suggesting that a strong motive for thus packing that jury had official inspiration from the point of view of finance. Some of the original promoters of the movement had not concealed a strong opinion that in their opinion Government guarantees are inseparable from the success of such a movement, at any rate at its start. There was no disguise that the public department which called the conference together, had not the least idea of making any admission in that direction. Hence the endeavour to enlist the interest of the railway companies, in the hope that they may see their way to finance schemes of the kind. But from the first this was fatal to the production of anything but a paper report.

When the chief financial support was looked for from the railway companies, and that condition became the preponderating one with the committee, the possibility of agriculture ever being extensively assisted by light railways became remote. So much was I impressed at the time with this that I addressed the following letter to the *Times*, which that journal was good enough to insert:

"LIGHT RAILWAYS.

"Sir,—A meeting such as that which yesterday I had the honour to attend leaves a deep impression on the mind as to its importance to the future of the population of this country when presided over and conducted as has been the case with the conference at the Board of Trade by Mr. Bryce, and attended by delegates from every affiliated interest.

"Unavoidably some aspects of the question received undue attention, and others were overlooked for want of time. One which especially interests agriculturists, as the shorthand writer's notes will show, has been altogether unnoticed. I refer to the conditions which must guide the construction and working of light railways if they are to be made available for providing useful transportation to or from the homestead, and to or from any part of the farmer's holding, at which his crop can be collected.

"In the sugar and cotton plantations abroad, for instance, portable railways, of the same gauge as the lines to which they form temporary feeders, are laid on to the cultivated lands, and are shifted when required.

"The weight of these rails and the trucks that can be used on them must be well within the physical power, for laying and working, of the men and horses on the farm. The well-known gauges and weights for such lines should govern the same conditions in the light railways for agricultural districts now under consideration, so that each cultivator being provided with the necessary equipment, costing £200 a mile (less than a wagon and team), can run the trucks from a siding to any convenient point of his land, whence his crop can be taken on rails right away to its destination, and to which can be brought all that it is necessary he should procure from a distance.

"It is certain that anything that does not permit of such provision will fail to afford the relief to agriculture which was the primary object of the conference.

"The conditions as tothe size of holdings, as to the *petite culture*, as to the share which women and children take in producing the larger portion of the small produce which finds its way to us from the Continent, are so different here to what they are in, say, France, Belgium, and Denmark, that the example of what the light railways do there for the agriculturist is not quite applicable here.

"It will therefore be inferred that the conclusion to which I would lead is—that the light rail, or tram, ways of 1½ft. to 2½ft. gauge, requiring a width of ground of 4½ft. to 6ft., and costing altogether under £1,500 a mile, is the character of line for which legislation and regulation should be most urgently sought.

"I am led to ask you to allow this view of the question admission to your columns, because I, with others, came away from the conference with the fear that it may be lost sight of, instead of being made almost paramount, if real assistance to agriculture is intended.—Your obedient servant,

"C. E. WEBBER."

The Portrush and Giant's Causeway Light Railway is, in contradistinction to the Irish light railways I have already mentioned, a light railway on a public highway. It has been 12 years running, and is one of several examples which show that Ireland has been far in advance of the sister isle in some important features of this kind of locomotion. The road is

Digitized by Google

worked by electricity, the conductor being of iron with a T section, the flat side being turned up, supported on wooden cleft posts at a height above the ground of about 2ft. 6in. I do not refer to this part of the construction as a sample of electric traction—the objections to it are sufficiently numerous to prevent their being repeated, and any description of them being of service here; but as a line bordering the hedgerow on one side of a road, which is about 30ft. from fence to fence, it is a very remarkable instance of what can be done. The line, which is 3ft. gauge, almost throughout its length skirts the highway, without any intervening fence, and is carried in the street right into the town of Portrush up to the railway station. When I saw it the streets and highway to the Causeway were as crowded with tourist traffic, vehicular and pedestrian, as any part of Ipswich and its environs on a market day. Yet no one seemed to take any notice of the not infrequent trains, even when they passed along by the kerb of the street footways, or to regard them as a source of danger not as easily avoided as any other vehicular traffic. In the town, and for a mile outside, each train, sometimes containing 120 passengers, is drawn by a steam locomotive; beyond that the electric traction comes into action. The usual train consists of two or three cars, but in the tourist season the trains have five or six. For these extra loads the steam locomotive runs all the way to the Giant's Causeway to help the electricity.

The chief feature in which this line is an example, is that small steam locomotives with short trains for goods and passengers have been worked for years alongside a public highway of ordinary width into a country town and through its streets with very rare cases of accident, and less in proportion to what is inseparable to the ordinary traffic in country roads which lead into a country town. The line is practically in the footway, and pedestrians step aside when they see a car approaching. At one point there is a siding across the road into a large lime quarry, so that the lime-trucks are taken into Portrush, about three miles, and the empties returned at a very trifling cost. An interesting feature, but one which is not in any way essential to a more modern electric railway, is the way in which the conducting-bar I have already mentioned is discontinued at each gate into a field, the current being carried by means of a covered cable under the ground between the ends. This I mention only to show that frequent gates into roadside fields are in no way an impediment to the use of light railways alongside roads in country districts.

According to the published reports in the year 1894, the total number of train miles run was 31,130, of which 10,487 was at 1s. 6d. a mile, by steam, and 20,643 was at 3½d. a mile, by electricity; but I have some doubts as to the accuracy of this comparison. This is essentially a passenger line, the traffic showing a total number of passengers of 93,917, the goods carried being no more than 26 tons, exclusive of parcels. This line, except in the town, is single. It is 8½ miles in length, and has cost £45,312 to construct and equip. It has never paid any interest on the £20,500 of share capital originally subscribed. The profit on the working in 1894, without placing anything to reserve, barely pays 3 per cent. on the amount raised by loans.

The subject of investigation to the engineer is how far experience would prove whether £5,448 per mile was excessive or not. There are elements of waste which are obvious—namely: (1) That the water power which generates the electricity is deficient in volume during the period of greatest traffic. (2) That the system of conductor used is unnecessarily costly, because of the frequency of the points all along the line at which it has to be interrupted, and continuity obtained by a length of costly underground cable of large section. (3) That there are evident causes of loss of electrical energy in the bad insulation of the bare conductor and the frequency of joints. (4) The necessity of supplementing the electric traction with steam locomotives makes heavy trains obligatory, and the waste of mixing the two kinds of traction will be obvious when the irregularity of the load which each has to take is considered. (5) All the advantage which electric traction gives of being able to run light loads at frequent intervals is lost, as the line is not constructed to provide for such a service; and it may also be said that, as the heavy passenger traffic chiefly reaches Portrush by rail, it is an obligation to have long trains to clear it.

It is quite certain that 7½ miles of the permanent way, with the rolling-stock added, exclusive of the locomotives and electric motor gearing, could have been provided for £1,800 a mile, if the rails had not had to be of the grooved form; the remaining mile might have cost at the rate of £2,800 a mile, making the total cost £16,300. How the cost of the traction—*i.e.*, the electric plant and equipment—and the steam locomotives, lands, and buildings came to £29,000 more requires explanation which I am not in a position to give. The only excuse which I conceive can be offered is that the line was built so long ago as 1882. The names associated with its initiation are those of Lord Kelvin and Sir William Siemens. One feels that the association was of more philanthropic than practical value. I mention this in particular, as it is necessary to forestall objections to the success of light railways which might be offered on account of the financial failure of an undertaking connected with such names.

Continental Light Railways.—Although not strictly dealing with engineering questions, the reports which Government has received on the subject of light railways on the Continent are important in their bearing on the subject under consideration. On December 4, 1894, Lieut.-Colonel Addison, R.E., reported to the Board of Trade on the light railway system in Belgium. He states that the Société Nationale des Chemins de Fer Vicinaux had 58 lines, with a total mileage of 730, and that projects were under consideration involving about 900 more miles. About 615 miles have a gauge of one metre, the rest is above a metre.

The average cost of construction was	£2,688
The amount paid for land less than (per mile)	220
Total (per mile).....	£2,908

The company has 245 locomotives, 663 passenger carriages, and 1,574 wagons and vans; generally 18-ton locomotives, some nearly 30 tons; of the wagons 70 per cent. carry 10 tons, the remainder five tons, a few 20 tons. The working expenses, 71·31 per cent. The proportion of the receipts from passenger and goods was 72 to 28.

Lieut.-Colonel Addison reported on his inspection of a line intended primarily to serve an agricultural district, and I have pleasure in drawing attention to it in detail: "This line is about 12½ miles in length, and is mainly dependent upon its goods traffic, which produced last year about 60 per cent. of the gross receipts of the line. Like all the Vicinaux railways, it is constructed on the road, excepting where steep gradients, etc., make slight diversions desirable. Usually a line of way is formed at one side of the road, raised slightly by ballast, etc., and separated from the remainder of the road by kerbstones; it resembles a footpath alongside a county road. In this way the railway is not available for ordinary carriage traffic, nor is it used by pedestrians. Through villages and where roads have to be crossed the line is of the usual tramway type. The line is of one metre gauge, with steel rails weighing 21½ kilos (42lb. per yard). In the towns, I believe, they use a deeper rail, weighing about 60lb. per yard. The rails are of the 'Vignolles' type, secured by dog spikes to creosoted sleepers about 4ft. 8in. × 8in. × 4in. Points are worked in the country by a lever at the side of the line, and in towns by a key fitting a screw-head placed between the rails."

Colonel Addison adds: "I did not obtain details of the curves and gradients of the Andenne-Eghezée line, but, as examples of the Vicinaux system, I take three lines, amounting to 45 miles in length, where the sharpest curves are 30 metres, 35 metres, and 40 metres respectively—*i.e.*, about 1½ to 2 chains radius. On the same lines there are gradients of 1 in 20 and 1 in 25. Round the very sharp curves, gauge ties are used to prevent the rails from opening. Guard rails are only used in towns. The speed is limited by regulation to 30 kilometres (about 18 miles) in the country and six miles per hour in towns and through villages; the time allowed in the time-table for the journey from Andenne to Eghezée, 12½ miles, averages 1 hour 25min., but one train in the day each way only takes about 1 hour 5min. The engine of the Andenne line, 18 tons weight, had six wheels coupled, each of 3ft. diameter; all moving parts were cased, and it was driven from either end (the driver of course always being in front). It was, in fact, an ordinary tramway locomotive. The engine was only provided with a hand-screw brake. I notice in the police regulations issued from the office of the Minister of Agriculture, etc., that the brakes on the engine wheels should be sufficient, alone, to stop the train on the steepest gradients in a length of 30 metres (33 yards). The engine always carries two men, a driver and a stoker. The train in which I travelled was composed, at starting, of one goods wagon next to the engine, one passenger carriage, and one fourgon, or luggage van; subsequently we dropped the goods wagon, but picked up three more wagons. The mixed trains usually have one van—in front of the train in one direction, and in rear on return journey. The van carries any passenger luggage and goods of small bulk. When not employed elsewhere the guard rides in the van, and makes out his way-bills, etc. For the suburban passenger traffic there is usually no van, but the society has a certain number of vehicles forming a second-class compartment and a small van. Vans have a post office letter-box, in which letters can be posted at the various halting places. There were several sidings on the Andenne-Eghezée line at the side of the road, so that carts could draw up alongside the goods wagons either to load or unload them. The running line is then outside the siding, on land acquired for the purpose. Sidings on the level usually had two dead ends, roughly made with a bank of earth and a few timbers. The stoker acts as foreman shunter at the sidings. The train only picks up loaded wagons, and does not stop to load *en route*. There were no signals of any description in use on the line I examined. M. de Burlet informed me they were only used at specially dangerous points, such as level cross-

Digitized by Google

ings over main lines of railway, where there are safety points, and a signal indicates to the driver when he is approaching these points. Before sunrise, after sunset, and during foggy weather, the locomotive carries two white lights in front, one on either side, and a green light is attached to the tail of the train. A room in an inn generally forms a waiting-room for passengers, and a place where parcels can be left, either until called for or to be picked up by the train. No tickets are, however, issued, or ordinary station business transacted. I believe it is not usual to make any payment to the proprietor of the inn, who gladly affords these slight facilities in return for the custom brought to the house. In addition to the stations as above, there are also fixed points (with a notice-board only) where the train stops if there is anyone to pick up or set down—such as at important cross-roads, etc. At Eghezée the Vicinal railway connects with the main railway system. There is, however, neither here nor elsewhere any physical junction of the metre gauge with the 4ft. 8½in. gauge of the main lines. Riders, drivers of carriages, carts, etc., are warned upon the approach of a train to keep at least 5ft. clear of the rails. If the rider or driver is not sure of his horse, he is enjoined to lead it until the train is passed. Before crossing the railway persons are instructed to ascertain that no train is near. The level crossings of roads, excepting in a few instances, are not watched or guarded in any way."

Last month reports on light railways from her Majesty's representatives abroad were presented to Parliament. These reports were actually made to the Foreign Office in 1894, and refer to Hungary, Belgium, France, Germany, Italy, and the Netherlands. Her Majesty's representatives were requested to deal with (1) the mileage, gauges, etc., of the lines; (2) questions as to the means of providing capital; (3) working of the goods traffic with reference to the advantage to and the stimulation of the agricultural industries; (4) as to the carriage of passengers.

By far the most carefully worked out report is that by Mr. Stovin Warburton, consul at La Rochelle, on the tramways of the Charente Inferieurs. It is well worth the consideration of any community which may be considering the subject, because it is very discouraging, at first sight, but to my mind its chief value lies in its suggestiveness of what should be avoided. The empiricism of French finance and French red-tape comes out in every line. While I have the greatest admiration for everything done by French engineers, their legislators, small and great, are the least practical men in Europe. For instance, if more than two-thirds of the length of one of these lines is along the side of a roadway it is called, and worked as, a tramway; and under the opposite conditions it is classed as a railway. Bureaucracy shines out in the classification of the sources of guarantees of capital. The results are that both from the contractor's and the guarantors' point of view these lines do not pay. To quote the Consul: "The question naturally arises as to the benefit derived from them by the districts into which they have been introduced, and on this subject, having consulted persons competent to form an opinion, I have found it to be generally unfavourable. . . . They run through an agricultural country principally, so that it is to persons engaged in this occupation we should expect the principal benefit to accrue; but I believe that they will be very little used by most of them. The line passes by hundreds of farms of moderate size (say, from 20 to 200 acres), mostly tillage, which necessitates the use of horses and carts, several of which are generally kept on each farm. The farmers have produce to sell, but it is generally sold at the different market towns for 10 or 12 miles round, and delivered at the buyer's house. The tramway only runs from one point to another, and if it passes through a certain number of market towns, it leaves a far greater number equally near to any particular farmer untouched, so that in their case it is of no use to him at all. But even when it runs to the exact place to which he wants to send a load, he has first to cart it from his farm to the tramway, then load it on the wagons, and at the end of the journey put it on another cart to get it to the house of the purchaser, if sold; while if not, it has to be sent home in the same way: so that there are very few farmers who do not prefer to load their stuff and send it direct to the place of sale than to go through all these operations; and the idea of running sidings from the lines up to the farms is entirely illusory in this country, for no one would think of doing it."

He answers the question which rises to everyone's mind—namely, how the financing of these lines was made so easy—by a description of French legislation on the question of assistance to public works—which ought to make us thankful that our form of government has a fairly strong, independent, and common-sense executive, which practically is the only means of keeping political jobbing of all such kinds in check. He writes, "It is simply because of the great facility in France which exists of obtaining public money for these and other undertakings which would never have been attempted if they had to be made with private capital and for commercial reasons."

In the United Kingdom, only in Ireland as yet have the public purse strings been relaxed in consequence of the importunity of its representatives in the House of Commons. Districts in Ireland in receipt of State aid for public work are called "being spoonfed." In France the efficiency of a representative is measured by the amount of public funds he can direct to the help of local undertakings. The effect on the local taxation (besides that of the State) in France is very insignificant, the rise between 1862 and 1890 being from 15s. to £3. 4s. per head of population. The gauge of these lines is one metre, and the locomotive weighs 15 tons, and there is no motive for the contractor to keep the capital cost below £2,735 per mile. I submit that for the class of traffic, this gauge, these weights, and the costs are all much too high, and that the cause of the failure described lies in the fact they are not adapted to the wants of agriculture; and here, I repeat, the instincts of the so-called purely railway engineer have been at fault. If any local authority wishes to see what can be done with an 18in.-gauge line, with locomotives and rolling-stock to match, they have only to visit Woolwich Arsenal or Guinness's Brewery in Dublin, and see the simplicity and safety of its working, surrounded by crowds of men and vehicles, irrespective of the nature and weights of the loads that pass over these lines, as compared with what would be usual in country districts.

One of the best popular descriptions of pioneer and portable railways was read in June, 1891, before the Society of Engineers by Mr. John Kerr, one of the managing directors of Messrs. Dick, Kerr, and Co., and published in the *Proceedings* of that body. I do not propose to take up your time by repeating the details of construction of these light lines, varying between 16in. and 24in. gauge, as they are probably well known to all my audience who are engineers; but I cannot refrain quoting one paragraph from the paper, as it is essentially practical: "A man with an equilibrium tipping wagon can take a cubic yard of earth on a portable railway a distance of 220 yards, discharge the same, and return in five minutes; whereas it would be good work for the same man to accomplish this task in one hour with a barrow. Taking a labourer's wage at 6d. per hour, the result is a cost of ½d. per cube yard with portable railways, against 6d. in the other. Assuming a week's work under both systems, the following results may be deduced—viz., if 10 wagons per day are used, 6,000 cubic yards can be carried at a cost of £12. 10s. on the portable railway, while the same tonnage by the more primitive method would cost £150. In this calculation the working day is taken at 10 hours. The capital outlay for the railway and 10 wagons would be £110; and if the work had to be executed in the same time with barrows, the outlay would be, say, £90 on account of 125 barrows, and further, if, as would happen in many cases, wheeling planks are required, the total capital expenditure on both systems would be practically the same."

Unfortunately, the illustration is not quite on all fours with work in harvest time, but it is instructive. Mr. Kerr emphasises the following points in favour of the portable portion of a line, such as might be connected with the siding of a permanent 24in.-gauge line laid alongside the highway, and which would be the property of the farmer, to be laid into the homestead or fields, and shifted from place to place as required: (1) extreme simplicity; (2) quick mounting and dismounting of the line; (3) perfect security for correct gauge when laying the line; (4) the accuracy and non-variability of the gauge; (5) the portability of rails and sleepers when detached; (6) that skilled labour for laying the line is not required; (7) the ease with which a turnout can be made by taking out a 15ft. section of the way and substituting a section of points and crossings, of which the varieties made, such as right-hand and left-hand, two-throw and three-throw points, are all simple and cheap.

As regards the rolling-stock, which within the farm would be operated by animal or manual power, Mr. Kerr pointed out the extraordinary proportion of paying, or live, load to dead load, in comparison with the proportion usual in the case of an ordinary railway wagon—in the former case being as 1 to 4, in the latter as 1 to 2. Of course the material and design of the body of the wagon is determined by the nature of the work. The safe load per wheel varies from a 10in. 16lb. wheel at 12cwt. to an 18in. 56lb. wheel at 40cwt. For heavy materials, such as stones, earth, etc., cheaply-constructed wagons to hold 10 to 27 cubic feet, and costing from £6 to £8 each, are also available. If the lengths of light material are not more than 4ft. or 5ft. bogies are not wanted, but that form might be very useful generally for farm work. A useful wagon for agricultural transport on a 24in.-gauge line would be 16ft. long by 5ft. wide. It weighs 72cwt., and costs £30 (*vide* illustration).

Mr. Kerr described what he called a "pioneer railway," which, so far as price is concerned, meets the case we have under consideration, particularly if we assume that if a local organisation takes up the question in respect to one agricultural area (say, the county of Suffolk) they might consider it in view of a maximum of, say, 200 miles within the county. Let us assume that there would be 20 lines, each of an average length of 10 miles, and that they would be worked with steam locomotive. The cost would be as follows: The railway should be 24in. gauge, and laid with steel rails, 20lb. per yard, having 2,112

Digitized by Google

steel sleepers (4ft. 6in. long over all) per mile—*i.e.*, sleepers laid 2ft. 6in. apart centre to centre. The illustrations will clearly illustrate the nature of the permanent way, and it will be seen that the sleepers have closed ends to prevent the ballast shifting. As regards the cost per mile for such a railway, at the present time, when prices are fairly normal, the total for iron-work, including rails, fishplates, bolts and nuts, sleepers and fastenings, would be £450.

200 miles of permanent way (24in. gauge), at £450	£90,000
200 miles of construction, at £450	90,000
Carriage and distribution of materials, say 11,000 tons, at £1	11,000
	191,000
7½ per cent. for engineering and sundries	14,325
	£205,325

or £1,027 per mile.

The expenditure on 20 lines would be:

40 stations and 20 workshops	£13,680
400 sets, points, and crossings	6,000
400 open goods wagons, at £25	10 000
100 covered goods wagons, at £50	5,000
40 timber wagons, at £25	1,000
40 brake vans, at £60	2,400
40 composite carriages, at £250	10,000
40 locomotives, at £700	28,000
	76,080
Add 7½ per cent. engineering, carriage, and contingencies	5,700
	£81,780

or £409 per mile. Total £287,105, or £1,436 per mile.

The above figure does not include anything for the purchase of lands, to which I shall refer further on.

In an investigation of the carrying capacity of these lines, it is assumed that the worst gradient would be 1 in 30, and that a train of, say, eight wagons, besides one brake van and one composite carriage, can be worked with a paying freight of 20 tons. If 20 such mixed trains run 40 miles a day each, we have a goods capacity of 800 train miles and 16,000 ton miles a day, or 4,944,000 ton miles a year. Taking one day with another, and considering the varying nature of the goods traffic, it may be estimated that the loads will amount to at least one-fourth the capacity, or 61,800 tons per annum on each of the 20 lines. This can bear an average rate of twopence (2d.) a ton per mile, and each line will receive for goods £515 per annum, or £10,300 on the whole. For the passenger traffic it may be estimated that on each line the carrying capacity will be per composite car:

	First class. 6 persons.	Third class. 24 persons.
Passenger miles per annum will be	98,800	296,640
The actual load estimated at one-fourth for first class at 1d. per mile, one-half for third class at ½d. per mile, will yield per annum	£77	£309

Total receipts passenger traffic, £386; or on the whole, £8,214. Goods and passengers together £18,514, which is almost exactly 1s. 6d. for each 247,200 mixed passenger and goods train mile.

Now as to expenditure: including all outgoings, I at once take my stand on 1s. a train mile. If the time would permit, I could describe economies in this figure, especially in the direction of oil-engine locomotives, or with boilers fixed with oil—both systems are practical. The Cork and Muskerry Light Railway Company in their report of February, 1895, on a length of 18 miles ran 83,872 train miles in 12 months, with a total outgoing of £3,938, or 11¼ per mile. The example least favourable to 1s. that I can find is that of the Clogher Valley Railway Company, in which the same figure is 15d. Now, these lines are constructed with a 5ft. 6in. gauge and worked as railways, and are burthened with all the expenses contingent on that system. The lines we are considering are essentially something much less costly in the working and construction: 1s. is therefore an outside figure. Of the above total of £18,514, there is therefore £6,540 left towards net revenue. To this may fairly be added as follows for each line:

Carriage of parcels and special objects	£30
Mails	15
Special excursion receipts (four days a year)	42
Advertising	12
Total	£99
Or on 20 lines	£1,980
Which, less 10 per cent. for expenses, gives an additional net revenue of	£1,782
Total net revenue	£8,322

This is at the rate of £2. 18s. per cent. on the capital. The above figures are compiled on each train, making but two return journeys on 309 days with goods and passengers, and eight return journeys with passengers on four days in the year. The extra net revenue, if traffic justifies an increase of trains in the day would (less a percentage) be to the good, and would increase the net profits. I have not included anything for the cost of intermediate stopping places, because on similar lines the total outlay is the cost of a notice board.

I now come to the all-important question of the purchase of lands, which some of my hearers may have thought I had overlooked. I have intentionally excluded it from the capital account, because I propose that it should be dealt with in the following way. The local authority—*i.e.*, the county council—will, no doubt, have full powers conferred upon them by Parliament to deal with this part of the question, and upon their manner of dealing with it, and upon the degree of their co-operation with and support of such a scheme, must depend the expenditure on the item of land. With the gauge proposed, and under the conditions described, I venture to predict that, including stations, the necessity for paying £50 a mile for land, including all the expenses of the local public enquiry—*i.e.*, £10,000 altogether—will be the outside figure, which at the present rate of borrowing powers and with sinking fund would come to £450 per annum. This is one burthen I propose the local authority should undertake as a fair expenditure to encourage local industry. The other is that they provide an annual amount to create a sinking fund at 1½ per cent. on the capital—viz., £4,305 per annum, total £4,755 per annum, or ·59 of 1d. in the £, to be added to present average poor-rate, which is about 1s. 6½d. In return for this support the local authority to have a claim on all net profits after 3 per cent. has been paid to the ordinary shares (say, two-thirds of the amount left over), also a representation on the direction, and the system to pass into their hands without further payment at the end of 42 years. We have been promised by two Governments that this matter shall at least have friendly assistance from the public revenue. In Ireland the baronies and the Imperial exchequer are burthened with much heavier charges per mile than those I suggest for Suffolk. The Treasury has already powers to help local rating for useful purposes. Can it apply them better than by taking half the above annual burden for Suffolk during 42 years? If the two-third deferred profits is also shared with the Treasury, and if an average for similar purposes of £2,377 per annum was granted to the 120 county councils in the United Kingdom it would only amount to £285,240 for 140 for 42 years. Everything points to an increase of traffic above that which I have estimated, and it may eventually prove the case that a loss in one area may be repaid the Treasury by a gain in another. In any case, it would be entirely optional with each local authority to deal or not with the initiators; and the Government share of the burthen need be undertaken only if the Local Government Board are assured of the prudence of the local authority in committing themselves to it.

Ipswich.

So as to bring the subject more home to the town in which we meet, I have prepared a map showing 11 or 12 possible light road lines radiating therefrom, designed to be constructed at the side of the public roads in the country and in the roadways where they pass through the streets; their routes and lengths are as follows:

Ipswich—Light Railways.

No.	Road route.	Mileage. Rural.	Urban.	Total.
1.	Nacton and Levington	3½	1¼	4¾
2.	Brightwell, Newbourne, and Hemley	6½	1½	8
3.	Kesgrave, Martlesham, and Woodbridge	5¾	3	8¾
4.	Tuddenham, Grundisburgh	5	1	6
5.	Westerfield, Witnesham, and Helmingham	7¼	¾	8
6.	Henley and Hemingstone	4¾	1	5¾
7.	Whitton and Claydon	2½	1	3½
8.	Bramford, Lt. Blakenham, and Offton	6¼	1	7¼
9.	Hintlesham and Hadleigh	8¼	1	9¼
10.	Copdock and Stratton St. Mary	9	½	9½
11.	Freston and Harkstead	5	1½	6½
		63¾	13½	77¼

Employing the figures in the former calculations, except, that £1,000 per mile is added for the cost of each mile for the cost of the urban lengths, the capital expenditure on the 77 miles, without the cost of land, will be £124,000. If 1s. 6d. a train mile can be earned with four return journeys on each of the 11 lines, and if the outgoings come to 1s., and if 6d. a train mile is profit, then these lines will pay 3 per cent. on the capital outlay. The guarantee charges which the localities would have to undertake are: first, the interest and sinking fund on 77 × £50 for land = £3,850, which is £173 per annum; second, the sinking fund on the capital outlay so as to secure quiet possession at the end of, say, 42 years—viz., 1½ per cent. on £124,000, 1,860; total guarantee for 42 years, per annum, £2,033. With the certainty of this annual charge being

Digitized by Google

steadily reduced, as already described, as time and increase of population and business produced their natural effect. If the Government join in the guarantee as suggested, the burthen would be only £1,017 per annum. From the point of view of construction, the following is a description of the various routes inside Ipswich, which present no engineering difficulties for a 24in.-gauge line.

General Description of the Routes Inside the Municipal Boundary.

No. 1.—To LEVINGTON—A 30ft. to 35ft. road to Derby-road railway station to junction with No. 2 from Henley. The railway bridge is 30ft. wide, with an easy gradient of 1 in 35 or 40. Cannot obtain access to the town by Nacton-road, Bishop's-hill, and Port-road, owing to the narrowness of some of the roads, which are only 22ft. wide, and the gradient at Bishop's-hill is heavy, being 1 in 20.

No. 2.—To HENLEY—The road is 30ft. wide to its junction with No. 1 near Derby-road Station. From this point 30ft. to 35ft. wide, following the tramway along Caldwell-road and St. John's-road to its junction with No. 3 at Spring-road. Gradients easy.

No. 3.—To WOODBRIDGE—The road is 30ft. to 35ft. along Spring-road to its junction with No. 2. From Crabbe-street to junction with No. 2 the gradient is about 1 in 25; from this point the joint lines Nos. 1, 2, and 3 will follow the tramway route along Spring-road (passing under the railway with a 30ft. road), St. Helen's-street, Carr-street, and Tavern-street to Cornhill. This is a good wide road, 40ft. wide in many places, and never less than 30ft., and has a double line of tram rails from the Shire Hall to Cornhill. The gradients are easy. Cornhill (opposite the Town Hall and post office) makes a good central junction or station, being a fine open space at the head of Prince's-street, which is the main road from the centre of the town to the station, and along which the tramway runs. This road (Prince's-street), which averages 40ft. in width, and is in no case less than 30ft., would take the traffic from routes 1 to 6 to Commercial-street, which is 40ft. wide, facing the goods yard of the Great Eastern Railway. Commercial-street, having little or no traffic, except for merchandise from goods yard, would form a good terminal depôt for goods, owing to its proximity to the railway depot. There is no access to this point for the above routes, Nos. 1 to 6, further east than Prince's-street, the streets eastward being narrow and crowded, a considerable portion of all of them being only 22ft., and many of them only 20ft. wide, so that the routes cannot in this case be varied from that shown on plan, past the Shire Hall to Cornhill and along Prince's-street.

No. 4.—To GRUNDISBURGH—The road is 30ft. to 35ft. wide until it reaches the N.E. corner of St. Margaret's Churchyard, where the width for a few feet is reduced to 24ft., owing to the corner of the churchyard projecting; but the road is being widened, and it is understood this corner will be cut away. Another narrow portion is about 30ft. in length at the north end of Northgate-street. This short length is only 25½ft. wide, and is caused by one very old building used as a second-hand furniture shop. The remainder of Northgate-street to its junction with Nos. 1, 2, and 3 in Tavern-street is 35ft. wide. The gradient is a little heavy from Hervey-street to St. Margaret's Church, about 1 in 30. The remainder is easy.

No. 5.—To HELMINGHAM—A good road, about 35ft. wide to its junction with No. 4 at Tuddenham-road. The gradient for a very short length to the junction with No. 4 is about 1 in 30. The other gradients are easy.

No. 6.—To HEMINGSTONE—Over 30ft. wide. This will be taken as shown on plan, along the new road, 35ft. wide, bounding the northern side of Christchurch-park to its junction with No. 5 of the Westerfield-road, the most direct route along the Henley and Fonnereau roads having a long heavy gradient of 1 in 18 or 20.

No. 7.—To CLAYDON—A good wide road, with a easy gradient, and having a tram line along it for a considerable distance. From the barrack corner to the top of London-road it may be taken either along St. Matthew's and Westgate streets to Cornhill, which is 30ft. to 32ft. wide, and almost level, or along Portman's-road and Mill-street to Prince's-street. The latter route is about 40ft. wide, easy gradient, and not much traffic on it. There is a tram line laid, but its use has been discontinued.

No. 8.—To OFFTON—30ft. wide along Bramford-road until it reaches Bulwer-road, where it narrows to 22½ft., with a gradient of about 1 in 20 to its junction with Norwich-road. By turning the route, as shown on plan, along Bulwer-road to join route No. 9 in London-road, the gradient is easy, and width not less than 30ft.

No. 9.—To HADLEIGH—The road has a width of 30ft., but the bridges across the railway are only 25ft. wide, and the bridge across the backwater of the Gipping or Orwell is only 18½ft., that across the canal, called the Handford Bridge, is 35ft., and the width of road from here to barrack corner is 30ft. to 35ft. Gradients easy.

No. 10.—To STRATFORD ST. MARY—30ft. wide to its junction with No. 9 at Crane Hill Villas. Gradient easy.

No. 11.—To HARKSTEAD—30ft. and 35ft. wide to Stoke Bridge, which is only 22ft. wide. It is of iron, and would admit of a footway being attached, which would increase the width to 30ft. From the bridge to Commercial-street is about 40ft. wide. Gradients easy.

The routes all end in leading up to the main-line railway station of the South-Eastern Railway Company.

My audience may expect me to deal with this illustration of Ipswich from the point of view of the cost of electric traction. There is no difficulty whatever in working the 77 miles suggested by such means if overhead conductors are permitted. The refusal to allow them is ludicrous in view of what is carried out in towns like Lubeck, Gera, Essen, Markberg, Chemnitz, Halle, Kiew, Breslau, Christiania, and 20 other towns abroad. All these lines could be worked from one central electrical generating station. But they could not be made to pay with the sparse traffic and low rates with which I have been dealing. For instance, the cost of the construction of the overhead and return conductors would be £29,000. The cost of the central generating station, without the price of the site, would be about £17,000; allowing for one loaded train to be running at one time on each of the 11 lines. Against these figures, together amounting to a total of £46,000, we should only save about £5,000 in the locomotives. There will be the saving in coal, but the labour would be about the same. With denser traffic electric traction has its own place, just as with very dense traffic there is nothing that can touch cable traction for economy.

Now, as to this question of gauge upon which the future of the subject in my opinion may turn. I see that at Tiptree, in Essex, a light railway is projected, and that 4ft. 8½in. is proposed. I hope someone is here to state the arguments in its favour. They cannot deny that if they are going to take the produce straight out of the fields and homesteads, say, to London, there must be a change of gauge somewhere *en route*. The difference between us, where it is to be? I say it is best at the railway station on the main line, where appliances for shifting goods are available. Does the engineer of the proposed Tiptree line really expect the main-line rolling stock to be taken along his light railway? Admit he does. Does he propose to continue his 4ft. 8½in. gauge into the fields and up to the homestead, and if he does, and locomotives are not available, with what means of traction will he move the wagons full of produce or manure? And who will pay for the construction of these branch lines? If he cannot answer us, where is the advantage to agriculture of the line? It is being continually asserted that a 2ft. gauge is nearly as costly as a 4ft. 8in. I maintain that those who make this assertion are unconsciously influenced by the question of profits. Otherwise, why are 600 miles of line in Bolivia, hundreds of miles in India and Burmah, the Beira railway in South Africa, and numerous lines for plantation work all over our Colonies, all of narrow gauge varying between 20in. and 36in., and that in countries where the standard of the main lines is, as with us, much wider? But to show that under certain conditions this difficulty of transfer of load at a change of gauge may be met, I have the pleasure to exhibit (it is almost the first time it has been publicly shown) a very neat model made for me by the Lancaster Railway Carriage and Wagon Company some nine years ago. It shows how the loaded rolling-stock of a 4ft. 8½in. gauge railway can be transported on a transfer trolley along a light railway of 2ft. 6in. gauge. I may say at once that while it saves the transfer of the load, it involves a cost in rolling-stock and weight of rails which does not meet our case.

As population increases over the face of this country—and no one knows what it may reach in the next 40 years—unless we look well ahead there will be fearful retribution. London is, I fear, hopeless: we shirk contemplating the engineering bankruptcy of London 40 years hence. But many of our provincial cities and towns, especially in the rural districts, have their chances still. If they now realise what is coming they will extend their jurisdiction over the widest suburban areas possible, not following, but in advance of the population; not so as merely to provide the workers with houses in rows, but also with gardens and paddocks. Easy, cheap, and fairly rapid, set-down-and-pick-up means of carriage in every direction will alone make this possible. The owners of land, if they are wise, will encourage this in every way, as it will restore values, which many of them have thought were rapidly disappearing.

I cannot occupy more of your time except by challenging proof that there is anything practical or magical in the use of the 4ft. 8½in. gauge for our light railways. The volumes that have been written on the battle of the gauge did their work, whether for good or ill. It is now time to reopen the whole question.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

ELECTRICITY IN MEDICINE.

From the earliest times the use of electricity as a curative agent in nervous and other diseases has been often described. Its application, however, has been largely left in the hands of electrical specialists whose knowledge of the human anatomy has unfortunately been exceedingly small. These gentlemen have numbered with them a certain proportion of quacks, who have conjured with the word "electricity," and by ribald advertisement have succeeded in deceiving a large number of people. The frauds thus fostered under the all-powerful name have brought a certain amount of discredit on this branch of the medical profession. There is also a deplorable want of knowledge of the subject amongst many medical practitioners. We are exceedingly glad, therefore, to see an article in a recent issue of the *Lancet* advocating the introduction of this branch of their profession in the education of medical students. We agree with this article in almost all respects, especially in the fact that electricity has been used in the past more as a stalking horse for rampant quackery, and in consequence of this has fallen into disfavour with a large section of the medical profession. The earliest cases on record in which good has been obtained from the use of electricity are perhaps more wonderful than true. In those days the apparatus at the command of the operators was of poor quality, and no means of measurement could be used. Since the year 1850 the subject has gradually occupied more attention, both from eminent specialists in England and on the Continent, and with the improved apparatus at their disposal exact information has been obtained to guide operators in the electrical treatment of the various diseases to which it is applicable. Although much has been written on the subject, we still think that there is room for a good and concise treatise on the advantages in various cases of using either alternating or direct currents.

Again, modern appliances are gradually being introduced which enable the operator to measure as well as regulate the amount of current applied. Instead of the old practice of regulating the quantity to just as much as the patient could bear, a definite prescription can now be administered which has been proved sufficient by previous experience. We cannot do better than to quote from the article referred to, which says, in support of the contention that more attention should be given to this subject in the various medical colleges, that "the range of utility of localised electrification is extending, and one very important point is becoming clear from the systematic work done in the electrical departments of the hospitals—namely, that patent electrical applications extending over long periods of time are able to do many things which might be thought unlikely or impossible by those who judge of electricity only by its immediate effects. There is not much which is instantaneous and there is nothing which is magical about the results of electrical treatment, and those who wish to benefit their patients by electricity must be willing to devote much time and patience to the treatment."

THE BRITISH ASSOCIATION AT IPSWICH.

It is seldom that the presidents of the British Association have so intimate a knowledge of its great work as the gentleman who is presiding over the present meeting at Ipswich. Sir Douglas Galton has for some forty-six years attended the annual meetings, and during the last twenty-five years has most ably filled the post of general secretary; so it is with no small amount of personal feeling that he reviews the scientific progress made during that period and the means by which the association has fostered this progress. There is no doubt that the meeting of so many distinguished scientists to discuss the latest developments in their respective departments is one of the surest ways of spreading knowledge, and Sir Douglas Galton may justly feel proud of the service he has rendered in this cause. We trust that the present meeting may uphold throughout the promise of the programme. The papers of interest to our readers are quite as numerous as usual, and we shall welcome some, especially as they are by new writers on the subjects treated. Thus Mr. Preece will enlarge on his subject of inductive telegraphy, but will add another paper on incandescent lamps, which is likely to open up new ground. Major-General Webber is a new writer both on light railways and on telephones, and we expect new ideas from him. On the whole, although the attendance is below the average, we fancy that the working element is strongly represented, and that the Ipswich meeting of 1895 adds much to our general knowledge.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

LIGHT RAILWAYS.

SIR,—In the *Times* on the 28th ult. there was an interesting account of a proposed light railway in the Peak district—interesting because the use of the side of an existing road is, no doubt, the proper method, and is in accord with the best examples of Continental experience. It is to be regretted, however, that a scheme of so much promise should have been presented to the landowners and others interested by those responsible in such a crude and imperfect manner.

In the first case it is called a light railway, which is incorrect, a nomenclature apparently of small consequence to the uninitiated, but of vital importance to those who are investors, if they are desirous of a dividend, though of small consequence to the promoters if their primary object is plunder. I am tempted to ask under what Act the promoters hope to obtain their powers to run 15 miles an hour on the public highway? It is true that the recommendations of the Light Railway Committee last year suggested an increase of speed, but at the present moment this is not to be obtained. It is also well known that the present conditions which apply to the working of light railways are more or less fatal to success.

As regards the cost of construction, it is unnecessary to say much beyond suggesting that £1,000 per mile appears a very low estimate, and is not borne out by Irish or Continental experience, and it may probably be found necessary to increase this.

It is stated that this line is proposed to be worked electrically—the announcement is interesting. To suggest that it ever will be is to accept Carlyle's definition of the inhabitants of the world, and apply it *without* the reservation to some of the votaries of electric traction.

To the technical men, who chiefly represent your readers, the reason is obvious; and if any further argument was necessary, the statistics given of the probable traffic and the service required for such traffic is convincing. The present price of electric traction is given at a fraction over 4d. per car mile; this is approximately the figure given as the cost of electric traction on the South Staffordshire tramways, the equipment and working of which is erroneously attributed to Messrs. Dickinson and Co., Birmingham.

It is misleading in the extreme to suggest, as is suggested, that the cost is the same for working 100,000 car miles on a light railway in Derbyshire, as is stated to be the cost on the South Staffordshire system, which is half the length, and runs 300,000 car miles per annum.

Taking the construction figure of the promoters at £1,000 per mile, the total cost, including a steam equipment and buildings, could not possibly cost more than £25,000; the total cost of working would, according to light railway experience in Ireland and the Continent, be about £3,500 per annum. If the promoters had such faith in the economy of electric traction that they believed they could work this proposed line at a total cost of 6d. per car mile, any economy made in this direction would be seriously handicapped by the interest on the difference of capital cost, given as £62,000.

It must not be assumed that I am in the slightest degree discounting the great value of electricity as an economical form of traction—on the contrary, I am a great believer in it—neither am I desirous of saying anything that would prejudice the introduction of light railways, but I do emphatically protest against the introduction of the mystic word "electricity" as a bait to the investor to subscribe to an over-capitalised line.

Tramways to this date suffer severely from over-capitalisation, mostly due to the introduction of the word "steam" and a promised reduction in working expenses. It is my object to prevent the over-capitalisation of light railways and subsequent failure due to the introduction of the word "electricity" and a suggested economy in working by its adoption.

It would thus appear to be good advice to the landowners, farmers, and others in the Peak district if they waited before investing any money in this scheme to the probably early alteration in the Legislature affecting light railways, as well as obtaining a little more experience before embarking in the use of electricity as a means of traction for rural lines.—Yours, etc., DIVIDEND.

FIRE.

SIR,—Mention having been made in the daily papers of the fire which occurred at our works last week, we beg to notify that our business is being carried on as usual, and that orders entrusted to our care can receive prompt attention. Through the prompt action of the fire brigade, the damage was restricted to one of the buildings in our works.—Yours, etc., GRIFFITHS BROS. AND CO.

Aquol Works, Bermondsey, S.E., September 11, 1895.

CITY AND GUILDS EXAMINATIONS, 1895.

ELECTRIC LIGHTING AND POWER DISTRIBUTION.

The following is the set of eight answers sent in by Mr. E. Basil Wedmore, of the electric lighting station, Temple Backs, Bristol:

2. What is the use of the series coil in arc lamps run in series with an unvarying current?

Answer.—The series coil is used to strike the arc—*i.e.*, to separate the carbons when the current commences to flow—the mechanism being balanced so that the carbons are drawn together by the weight of the moving parts when the current is not flowing.

6. How does slipping a copper tube over the core lessen the spark of an induction coil?

Answer.—The spark of an induction coil is due to the self-induction in the primary circuit. The effect of the

Digitized by Google

copper tube is to lessen the self-induction and therefore the spark. The action is similar to that which takes place in a transformer with closed secondary circuit. Currents are induced in the copper which, by Lenz's law, are in such a direction as to oppose the alteration of the magnetic field by which they are being produced, therefore the total variation of the magnetic induction is lessened, and consequently the self-induction of the primary circuit and the spark.

Note.—It is the rate of change of induction which is most affected by the eddy currents. The E.M.F., being a function of the rate of change, is kept low, and hence the sparking is reduced.

12. A series dynamo has an armature resistance of 0·4 ohm and a field resistance of 0·6, and gives 120 terminal volts at a given speed and current of 10 amperes: work out its electrical efficiency as a dynamo and as motor at that speed and current.

Answer.—As dynamo: At 10 amperes the drop of potential in armature and field coils = C R = 10 (·6 + ·4) = 10 volts.

∴ Total volts produced in armature = 120 + 10 = 130 V;
∴ total watts produced by armature = 1,300.

But watts given out at terminals = 1,200,

$$\therefore \text{Efficiency} = \frac{12}{13} = 92{\cdot}3 \text{ per cent.}$$

As motor: The back E.M.F. of armature at given speed is (as seen above) 130 volts. The drop of potential in armature and field coils at 10 amperes = 10 volts; ∴ to send 10 amperes through machine 140 volts will have to be supplied to terminals—*i.e.*, 1,400 watts supplied, 1,300 watts converted into useful work.

$$\therefore \text{Efficiency} = \frac{13}{14} = 92\ 9 \text{ per cent.}$$

Note.—This was the only correct answer received to this question.

13. Describe one kind of alternate-current motor.

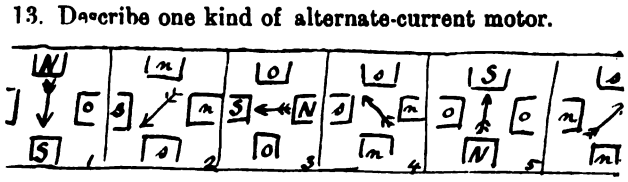

FIG. 1.

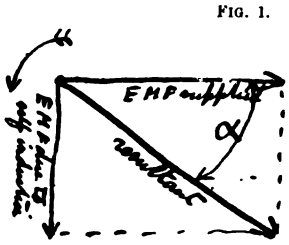

FIG. 2.

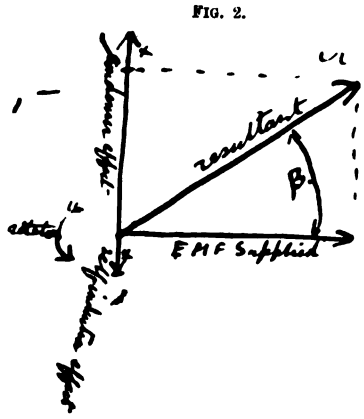

FIG. 3.

Answer.—The simplest form of alternate-current motor is one with a rotary field. In this motor the armature consists of an iron ring, disc, or drum, mounted to revolve on its axis, and usually wound with a copper wire forming one or more closed circuits. The action of the rotating field on such an armature is to produce polarity in the iron, both by direct induction and by means of currents induced in the copper circuits. It will be seen by inspection that the poles thus produced will lag behind the polarity of the rotating field, and consequently the ring will tend to follow the rotating field. It is obvious that the ring can never rotate as fast as the field, as in that case there would be no lag, and therefore no torque. The ring therefore rotates at a slower speed than the field. If the load on the armature is altered—say, increased—the speed of the ring will alter until the increased torque (due to the currents in the coils being increased by the increased cutting of lines of force due to the increased difference of speed) and the reduced speed overcome the load applied. The rotating field is produced from a two-phase current obtained either from a two-phase supply or by the conversion of a single-phase current into a two-phase one, as in the Ferrari and Brown motors. The conversion is effected by dividing the magnets into two circuits, every alternate magnet being on the same circuit, and making the phase of the current in one circuit lag behind the supply by means of large self-induction, and, as in the Brown motor, by making the phase keep ahead of the supply in the other circuit by means of a condenser. Assume the phase to differ in the two circuits by 90deg., and the diagrams (Figs. 1, 2, and 3) for a four-pole machine will prove that the resultant field rotates. The conditions necessary to obtain a difference of phase of 90deg. are represented thus:

$$\text{First circuit, } \alpha + \beta \text{ must } = 90\text{deg.},$$

which shows that efficiency of motor must vary largely with load.

Note.—The general tone of the answer shows that Mr. Wedmore understands the principles of construction of rotary-field motors, but in single-phase motors he confuses the starting arrangements with those used when the motor has attained its speed.

16. Give a rough sketch of a switchboard for a station with batteries and feeders and a three-wire system.

Answer.—See Fig. 4.

Note.—Only two balancing dynamos are shown, whereas large dynamos are usually connected across between the two outer wires. A convenient arrangement is also wanted for connecting any one feeder on to the charging side of the regulating switch.

18. What is the construction of an ohmmeter?

Answer.—An ohmmeter is an instrument for comparing the current which traverses a circuit of unknown resistance with that which is set up in a coil of known resistance when a similar E.M.F. is applied to both, thereby giving the resistance of the unknown circuit. The instrument consists of two coils placed one within the other, and at right angles to each other—one coil of low resistance being placed in series with the external circuit, and the other coil of high resistance is shunted across the terminals of the external circuit and series coil. Within the coils is a small magnetic needle, pivoted to revolve in the plane of the axes of both coils, and provided with an index arm. The needle takes up a position parallel to the field produced, which is the resultant of the two fields produced by

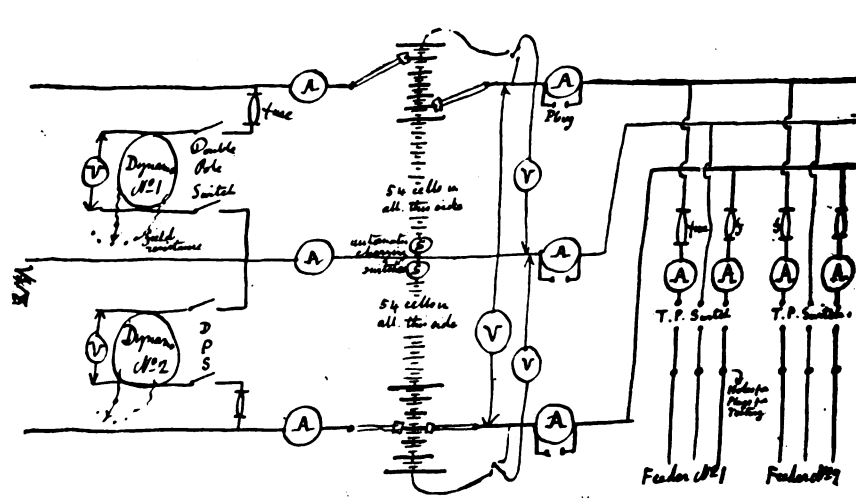

FIG. 4.

Digitized by Google

the two individual coils. The scale is calibrated to some convenient unit of resistance. Sometimes there is a commutator supplied to place some of the turns in the series coil in parallel or series, thereby altering the sensitiveness of the instrument. The E.M.F. applied is usually produced by a small hand dynamo (say V = 100).

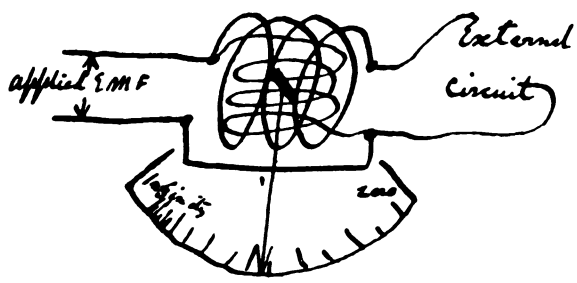

FIG 5.

20. How are the pull and self-induction of an electromagnet connected?

Answer.—The E.M.F. of self-induction of a given electromagnet is directly proportional to the number of turns in coil and to the magnetic induction in core. The turns being constant, the E.M.F. is $\propto$ to magnetic induction. The pull of the magnet is proportional to density of induction and proportional total induction, but density of $I = \frac{\text{Total } I}{\text{sec. area}}$; $\therefore$ as sectional area is constant, the density is proportional to induction, $\therefore$ pull is proportional to square of total induction.

$$\therefore \frac{\text{Pull of magnet}}{\text{E.M.F. of self-induction}} = \frac{I^2}{I}.$$

22. What magnetic quantities are denoted by the symbols H, B, and μ, and how are they related to one another?

Answer.—H denotes strength of magnetic field set up in air by a given magnetomotive force. B denotes strength of magnetic field set up in a given piece of iron when a magnetomotive force is applied which would set up a field, H, in air—*i.e.*, when iron is placed in field H in air the induction per square centimetre = B. $\mu = \frac{B}{H}$, and is called "permeability," and varies with the same sample of iron in various fields and with different samples of iron in the same field.

THE DOUGLAS AND LAXEY TRAMWAY AND SNAEFELL MOUNTAIN RAILWAY.

BY A TRIPPER.

Some little time ago, while paying a visit to the Isle of Man, I visited the Douglas and Laxey Tramway and the Snaefell line, just opened. Few people could realise, unless they had seen these lines, how immensely popular they are, neither would they credit the traffic which for a few months is carried and successfully coped with. Beyond this there is very little to excite those who have studied the question of electric traction, and this is disappointing to those who remember Dr. Edward Hopkinson's evidence before the Joint Committee on Protective Clauses, when he said that it was not only perfectly easy, but, in fact, a great economy to use a metallic return on tramways, and that he was then erecting such a line at Douglas. I suppose we shall never hear why, after many attempts, the earth return was finally adopted; but it is evident that the alleged simplicity and economy, though perfect in theory, were somewhat unruly in practice. We live and learn, and Messrs. Mather and Platt may live to bless the day when the Joint Committee discredited the evidence of their electrical adviser, when they equip, as I hope they will, some tramways under the existing Board of Trade regulations.

In the short time that I was able to spare to view this equipment I could not help feeling that the gods had favoured the contractors in this, I believe, their first attempt at tramway equipment, inasmuch as the conditions are so extremely favourable—first, in the permanent way, which consist of ordinary light steel rails, Vignoles type, flat bottomed, and spiked to cross sleepers, and, secondly, to the fact that the Board of Trade regulations are conspicuous by their absence. You therefore find some of the many conditions that rejoice the heart of the tramway manager, one of which is as much overcrowding in the cars as the trippers will agree to.

The cars are fitted with bogies. There are no outside seats, and each motor car is provided with two 15-h.p. motors and draws at rail car. The current is collected from the overhead conductor by means of a crossbar at each end of the car, the pressure of which is to a limited extent assisted by a spring; the conductor is generally very slack, and there is a considerable sag.

The Douglas and Laxey line has a generating station at each end, and a set of batteries of the chloride type near the centre. It would be interesting to hear authoritatively the practical results of these accumulators, the internal resistance of which would appear to be considerable. The rails are said to be bonded throughout. The method adopted is that of riveting two copper strips to the end of each rail under the flange, with a cross-bond at intervals; the exact value of this seemingly imperfect bonding will later on no doubt be fully determined.

The defects noticeable in another well-known installation of electric traction are also to be found here, the same amateur mechanical arrangements, the same disregard to profit by the experience of our American cousins, chief amongst which I noticed uncovered motors and gearing, courting as much detritus as the track will supply—to whose advantage?

In dismissing the tramway (so-called), and viewing the installation as a whole, one can only congratulate the company in the possession of a line where the margin between gross earnings and working expenditure is necessarily so large that they do not require an equipment which by the strictest economy only could pay a reasonable dividend.

The Snaefell mountain line also appears to obtain a large patronage. This is worked on the overhead system, and is similar in principle, as regards equipment, to the Douglas and Laxey. Its assistance enables you to reach the summit of the m untain by a line over four miles in length up a ruling grade of 1 in 12 to a height of 1,000ft., taking half an hour to do the journey. The permanent way is similar to the Laxey line, except for the introduction of a centre rail attached to the sleepers, on which an emergency brake can clip if required.

The cars, which seat I believe about 50 passengers, are equipped with four 25-h.p. motors, and they take the hill exceedingly well. In this case the accumulators are situated at the commencement of the line, the generating station being halfway up the hill. What is the benefit of having the accumulator-house so far from the generating station must be answered by those responsible. The whole of the return journey is done by gravity, and is at present unsatisfactory—it being exceedingly difficult to regulate the emergency brake clipping the rail to such a nicety that there is no jerking. What would naturally have suggested itself is the policy of using this descent for the generation of power with a corresponding economy. But as I have said before on these lines, there suggests to the uninitiated a reversal of the old saw, which will now read, "Take care of the pounds; the pence must take care of themselves."

THE NIAGARA INSTALLATION.

The following correspondence has taken place in the *Times*:

Sir,—Our attention has been called to a communication under date of July 15, from Prof. George Forbes, published in your columns. In view of the amazing statements of Prof. Forbes, we desire to give a few facts.

This company was not a submitter of plans in competition with others (as was Mr. Forbes) for prizes offered by the Cataract Construction Company in 1890, and it was not until a much later period that we became aware that Mr. Forbes had been a competitor and was continuing to

Digitized by Google

labour for the honour of furnishing an acceptable plan for the transmission of power from Niagara Falls to distant points.

At the period named we were convinced that such transmission was not possible except by means of Mr. Tesla's great discoveries, whereby alternating currents of two or more phases could be used successfully for such purposes, and we naturally preferred to defer the submission of a plan until the Tesla inventions could be more fully adapted to so large an undertaking.

After a lapse of two years, and prior to the design of the dynamo referred to by Prof. Forbes, this company submitted to the Cataract Construction Company plans and specifications for a dynamo, with a system of distribution for the operation of arc lights, incandescent lights, street cars, and for electrolytic purposes, including rotary transformers. Full information and particulars were communicated to the engineers and officers of the Cataract Construction Company. Owing to the purloining of our plans by a rival company, and for other reasons, all tenders for generators were rejected by the Cataract Construction Company, who afterwards, in September, 1893, submitted to us plans for a 5,000-h.p. generator, saying that such plans had been prepared by their engineers, and asking us to make a tender for its construction and erection. A careful consideration of the plans submitted disclosed the fact that if constructed according to such plans the generator would be a failure, and this company thereupon refused to tender on the drawings and specifications presented. We, however, offered to accept the general form of generator and to redesign it so that it would be a perfect machine mechanically and electrically, and to submit new plans and specifications upon which the company would tender. This was agreed to by the Cataract Construction Company, and the generators now in use at Niagara Falls were built by us according to plans and specifications prepared by our own engineers. There is about the same difference between the machine designed by Prof. Forbes and that designed by us as there is between the picture of a man and the man himself—the appearance externally being very similar, but internally there is no resemblance whatever.

Business relations were established between Prof. Forbes and this company in 1888 by the purchase of his patent for a meter operated by hot air currents, and he was afterwards employed by us as an expert in a patent case, and in making tests on transformers. He thus had every opportunity to become acquainted with our practice and ideas in connection with the use of alternating currents for light and power purposes, and also had an opportunity to see considerable of the early work on the Tesla motors. That such opportunities were valuable to him is shown by the fact that the first plan submitted by him for the transmission of power from Niagara Falls was almost identically on the lines that we had laid out for such work and freely discussed with him.

The following letter was received from Prof. Forbes about October 1, 1891 :

34, Great George-street, London, S.W.,
Sept. 19, 1891.

Dear Mr. Westinghouse,—I am going to read a paper on alternate-current motors. I want to emphasise the importance of your work on the Tesla motors. May I ask you kindly to allow me to have as full information as possible by instructing one of your staff to forward some details? I daresay you cannot give me all the facts I want, but if I indicate them generally perhaps you will give me some of the points. First, and most essential, I want a drawing to show the winding of the armatures, especially the unsymmetrical winding, which I saw last year. I should also like to have drawings of the complete machines, generator, and motor. The dimensions, weight, speed of revolution, output, and efficiency of any particular machine that you have made. What are the largest and smallest machines you have had giving good results? What is the period of alternations and E.M.F. you have used? What examples may I quote of their successful use in practice? I know that the development of the motor has been retarded by other than engineering difficulties. I am glad to learn that the financial difficulties of the company have been surmounted.

With kind regards, I am yours most truly,

GEORGE FORBES.

P.S.—I also want facts about the power when starting the motor.

To which reply was made as follows :

Pittsburg, Pa., Oct. 30, 1891.

Prof. George Forbes, 34, Great George-street,
London, S.W., England.

My dear Sir,—I desire to apologise for not having written earlier in answer to yours of September 19. I have given the matter very full and careful attention, and I have come to the conclusion that our company cannot afford at this time to make public the information it has acquired in its work on the Tesla motor. The Tesla patents and discoveries include many very important matters, and his patents particularly cover the multiphase forms of motors and generators now attracting so much attention.

You must have become aware that patent rights are no longer respected in this country ; that whatever is brought out and fully explained is immediately availed of by unscrupulous competitors; and we now feel it is a matter of great importance to maintain for the present, and until we are well established, what are properly secrets of the trade. To no one would I sooner give the information asked for than to yourself, and I hope the day is not far distant when we will be able, with safety to ourselves, to meet your wishes in this respect.

Trusting that you will appreciate the reason given for not promptly comply with your request.

I am very truly yours,

GEO. WESTINGHOUSE, JR.

In consequence of Prof. Forbes having written the foregoing letter without stating that he was a competitor for the honour that would accrue to the successful designer of a complete plan, our company, for that and other good business reasons, refused to permit Prof. Forbes under any circumstances to visit its works or to have anything to do with the designing, constructing, or testing of the generators, and we are not aware that he has ever seen the apparatus which is now in operation at Niagara and for which he seeks to claim the entire credit.

In conclusion, we desire to state that a complete plant, showing the universal application of the alternating multiphase apparatus, was erected in our works for the especial benefit of the officers and engineers of the Cataract Construction Company in the fall of 1892, which Prof. Forbes did not see, but which was undoubtedly explained to him, and which he had an opportunity afterwards to inspect, and did inspect, in our exhibit at the World's Fair, Chicago, in 1893. In this exhibit, generators, motors, and rotary transformers were operated at 3,600 alternations per minute, being practically identical with the frequency actually adopted at the Falls, and very different from Prof. Forbes's recommendation of about 1,000 alternations per minute.

Prof. Forbes made a suggestion for a device for commutating currents, in place of a rotary transformer, which device was built, and upon test the fact was disclosed that it was not anything like as good as the rotary transformer which we had designed and which form was afterwards adopted by a rival company, as Mr. Forbes says, on his recommendation.

We regret that there is occasion for stating the foregoing facts.—Yours truly,

WESTINGHOUSE ELECTRIC AND MANUFACTURING COMPANY
(Geo. Westinghouse, Jun , President).

Pittsburg, Pa., Aug. 29.

Sir,—In the *Times* of to day appears a letter from the Westinghouse Electric and Manufacturing Company, of Pittsburg, Pa., on the above subject. As silence on the part of Prof. George Forbes might be liable to misconstruction, I beg that you will permit me, his private secretary, to mention that he is far away from England, on a journey to South Africa on an important engineering work, and consequently it must be some weeks before he can have the opportunity of replying to the Westinghouse Company's letter.

In the meantime, I may, perhaps, be permitted to quote two extracts from letters written by (1) the Cataract Construction Company, through its president, Mr. Edward D. Adams, to Prof. Forbes, in November, 1894, and (2) the first vice-president of the same company, Mr. F. L. Stetson, which appeared in your columns of the 3rd ult., which I think sufficiently meet the principal contentions of the Westinghouse Company. Mr. Adams wrote :

Digitized by Google

We further recognised that, in the advocacy of the use of the alternating current and of low frequencies, you were a pioneer, and we join you in the feeling of just satisfaction at the conclusion which has now been reached in respect of those features. In this, too, your independence of thought and action has been of particular service, while, through your original design of the stationary armature and revolving field of the generators, adopted by us, you have relieved us of one most embarrassing question in connection with the relation of the generator to the turbine.

Mr. Stetson, in your columns, said :

But the development of our plan must have been long delayed had it not been for the courage and comprehensive knowledge of Prof. Forbes, who alone stood for the absolute commercial advantage of the alternating current, and for his admirable conception of his 5,000-h.p. dynamo, so wonderfully worked out by the Westinghouse Company as to yield 5,315 h.p. in the actual test on June 28, 1895.

Prof. Forbes is entitled to the credit, as he must bear the responsibility, of the results of the advice given by him as to the three points stated in his letter of July 25 ; and we have followed his advice, perhaps not as far as his courage would carry him, yet beyond the former practice of the manufacturers, who now fully concur in the wisdom of his recommendations as adopted.

Two of the three points referred to by Mr. Stetson (which alone need be quoted here), as stated in Prof. Forbes's letter in your issue of July 27, are : "(1) The selection of alternating currents, and (2) the reduction of speed of alternations as low as was possible."—I am, Sir, your obedient servant, HERBERT E. MITCHELL.

34, Great George-street, Westminster, S.W.,
September 10.

ELECTROSTATIC VOLTMETERS.

We illustrate herewith two of Ayrton and Mather's electrostatic gravity voltmeters, made by Mr. R. W. Paul, of 44, Hatton-garden, London, E.C. The small-pattern instrument is constructed on the same principle as the standard or large pattern, for which the following claims are made : simple working parts, entirely

screened from outside electric and magnetic action, accurate calibration, perfect constancy, large open scale, dead-beat, absorbs no power, provided with safety fuses, fine workmanship and finish. The smaller meter is, however, simplified by the omission of the index-clamping device and of the magnet for damping.

The other meter is the spring control for low pressures. It is claimed to be correct for any frequency, and not affected by outside electric or magnetic action. The needle is of aluminium, balanced, and pivoted in jewelled centres ; the total weight of the moving part being less than 25 grains, it has a nearly dead-beat action,

and is free from creeping errors. All working parts are insulated from the case. Safety terminals are provided with fuses in capped glass tubes, which are accessible with the same readiness as those of the standard pattern. The scale is enamelled and clearly marked ; it is curved to a radius of 4in. and is 5in. long. The instrument may be screwed to a switchboard or stand upon a shelf. It is specially designed for central-station use.

THE INSTITUTION OF CIVIL ENGINEERS' PREMIUMS.

The council of the Institution of Civil Engineers invites original communications on the subjects included in the following list, as well as on any other questions of professional interest. For approved papers the council has the power to award premiums, arising out of special funds bequeathed for the purpose, such as the Telford Fund, the Manby Donation, the Miller Fund, the Howard Bequest, the Crampton Bequest, and the Trevithick Memorial Fund.

The council will not make an award unless a communication of adequate merit be received, but will give more than one premium if there are several deserving memoirs on the same subject. In the adjudication of the premiums no distinction will be made between essays received from members of the institution or strangers, whether natives or foreigners, except in the cases of the Miller and the Howard bequests, which are limited by the donors.

LIST.

The most economical methods of handling large masses of excavation, as exemplified in modern canal construction
The measures necessary for the improvement of cana navigation.
The methods adopted in carrying out large dock and harbour works, with descriptions of the plant employed.
The appliances for dredging and for removing rock in deep water, with details of the time occupied in the various operations.
The application of compressed air, steam, and hydraulic power to rock-drills.
The construction, equipment, and working of light or economical railways of a permanent character.
The design and construction of railway carriages, having reference to (*a*) lavatory accommodation, (*b*) provision for refreshments, and (*c*) sleeping arrangements.
The use of compressed air in subaqueous tunnelling.
The modern methods of pumping compared as to cost and efficiency.
The use of steel in the construction of large water-tanks.
The employment of storage reservoirs in irrigation and in the conservation of rivers.
The purification of sewage by precipitation, filtration, electrolytic, bacteriological, and chemical processes.
The use of ash-bin refuse in towns for the production of steam.
The purification of large quantities of water after its use in manufactories.
The methods of enriching coal gas and their effect on its calorific and illuminating values.
The production and enrichment of water gas.
The methods of conveying and of using natural gas.
The utilisation of heat (*a*) generated in the compression of air and other gases ; (*b*) carried away by steam-engine condenser water ; and (*c*) contained in boiler furnace flue gases.
The methods of condensing steam by the use of moderate quantities of water.
The theory and development of the compound steam-turbine.
The methods of removing moisture from steam, and of reducing losses by radiation from steam-pipes.
The production and use of super-heated steam.
The recent development in gas engines and oil-engines, including a comparison of the relative merits of the several cycles, with reference to "after-burning."
The application of oil and gas engines to tractive purposes on common roads and on tramways, and to the propulsion of vessels.
The design and construction of large turbines.
The methods of testing the lubricating values of oils, greases, etc.
The comparative merits of blast and reverberatory furnaces.
The influence of carbon on iron.
The magnetic properties of iron and steel.
The manufacture of steel for structural purposes.
The strength of steel shafts, tubes, and cylinders.
The mining of thin seams of coal.
The influence of coal-dust in contributing to colliery explosions.

Digitized by Google

The efficiency of centrifugal fans for forced draught and for the ventilation of mines.
The underground arrangements in collieries.
The drainage of mines by pumping and by tunnelling.
The extraction of metals from their ores by electrolytic processes.
Argentiferous lead smelting in water-jacketed blast furnaces.
The methods of gold-mining in California.
The occurrence, production, and uses of (*a*) asbestos, (*b*) arsenic, and (*c*) mercury.
Aluminium, its manufacture, properties, uses, and alloys.
The metallurgy of chromium, molybdenum, and other rare metals, and their use in the manufacture of steel.
The design, construction, erection, and working of modern stamp mills.
The machines for raising mineral tailings, as lifting wheels, pumps, dredgers, etc.
The most suitable steam-power equipments for electric light stations.
The utilisation of electric lighting plant during hours of small demand.
The utilisation of electrical energy in the form of heat.
The regulation of electric pressure in large lighting circuits as carried out at the engine, the dynamo, or the exciter.
The theory and practice of the transmission of power by alternating currents.
The use of electrical motors for driving machines in textile factories and in engineering workshops.
The first cost, facility, and economy of operation of electrical traction on railways with heavy trains and on tramways.
The construction and working of electrical lifts and cranes.
The electrolytic action of return currents in electrical tramways on gas and water mains, and the best means of providing against electrical disturbances.
The most suitable alloys for the working parts of pumps for lifting corrosive liquids from mines, etc.
The methods of preventing or arresting the corrosion of hydraulic rams of large diameter.
The use of the die-press in workshop operations.
The modern rolling mills of the United States.
The appliances used in the manufacture of smokeless powder.
The transport, storage, and manipulation of grain.
The different systems of refrigeration, and of appliances for the storage and preservation of food produce.
Brine-pumping and the manufacture of common salt.
The present limits of speed at sea.
The relative advantages of single screws, of twin screws, and of triple screws in large vessels.
The use of electrical machinery for lighting and the transmission of power in warships and in the mercantile marine.
The most recent types of (*a*) passenger and mail steamers, (*b*) cargo steamers.
The best position for torpedo-discharging tubes on large vessels, with a fixed direction, or trainable.

The communications must be forwarded to the Secretary, the Institution of Civil Engineers, Great George-street, Westminster, London, S.W., from whom any further information may be obtained. There is no specified date for the delivery of MSS., as when a paper is not in time for one session it may be dealt with in the succeeding one.

THERMODYNAMICS OF GALVANIC POLARISATION.

Messrs. Hans Jahn and Otto Schönrock, in *Zeit. Physikal. Chem.*, develop from the thermodynamical standpoint, formulæ for the cathodic, anodic, and total polarisation for a solution. From these it is indicated that if the potential difference between a metal and its solution be substracted from the total polarisation, the difference should be constant in the case of the strong oxy-acids, a result agreeing with experimental data. The E.M.F.'s of various chains are also calculated and compared with the found results. Under similar conditions all oxy-acids should show the same potential difference at the commencement of the gas development, a result experimentally obtained by Le Blanc. The polarisation should be independent of the concentration, and experiments with sulphuric acid gave the following results: normal solution 2·3977 volts, decinormal solution 2·3922 The nature of the electrode affects the polarisation; the size, however, should not affect the final value. In the case of salt solutions, similar laws obtain, the polarisation increasing with the polarising E.M.F. and being independent of the concentration. The polarisation of dilute solutions of bases should be equal to that of dilute acids, and this conclusion is verified by experiments with solutions of potassium and sodium hydroxides, ammonia, ethylamine, and diethylamine.

LEGAL INTELLIGENCE.

THE DUBLIN AND KINGSTOWN ELECTRIC TRAMWAY.
Application for an Injunction.

On September 10, in the Exchequer Court, Dublin, before Mr. Justice Murphy, sitting to hear vacation motions, the Pembroke Township Commissioners appeared to apply for an interlocutory injunction restraining the Dublin Southern District Tramways Company, by themselves or by their servants or agents, from entering upon and breaking up, opening, or excavating the roads or pathways of the township alongside their tramway. The motion was listed for hearing on a previous day, but it was then postponed for the present sitting.

Messrs. Piers F. White, Q.C., A. F. Elood, and T. C. Drury (instructed by Messrs. D. and T. Fitzgerald) appeared for the Pembroke Commissioners. Messrs. D. B. Sullivan, Q.C; Thomas O'Shaughnessy, Q.C.; and R. H Sheil (instructed by Messrs. O'Connor and Dudley) appeared for the Dublin Southern District Tramways Company. Counsel for the contractors (The British Thomson-Houston Company, Limited), Mr. John Gordon, Q.C. (instructed by Messrs. Casey and Clay).

Mr. White, Q.C., in opening the case, said the Commissioners had control of the roads in the township, and the Act under which the tramway line was being constructed (the Tramways Act of 1893) gave no power whatever or right to the defendants to place electric wires underground. The only power under that Act which the defendants had for breaking up the roads was for the purpose of putting down poles to carry overhead wires. The defendants proposed to dig up the township roads and lay down cables and wires, although when the Bill of 1893 was before Parliament an undertaking was given by the defendants in the course of negotiations that only an overhead system of wires would be adopted. Mr. Fitzgerald, the solicitor to the Commissioners, had made an affidavit in which the nature of the negotiations was fully set out. An affidavit had been made by Mr. Robertson, the defendants' secretary and manager, in which it was stated that the overhead wires were, of necessity, small, and consequently they were insufficient to carry a continuous or even current along the whole line This difficulty would be got over by feeders of much larger dimensions and less resistance running from the power-house underground, and connected at regular intervals of half a mile with the overhead wires. There Mr. Robertson stated that the overhead wires were not sufficient for their purpose, and it was, in consequence, proposed to break up the township roads, dig trenches in them, and lay in the trenches so dug wires of much greater diameter than those running overhead. That would be all very well if the defendants had power to carry it out, but they had no power under their Act to break up the public roads. They could not do that without having entered into a contract with the Commissioners in the first instance, and no such contract had been entered into.

Mr. Justice Murphy said it was a serious thing to interfere with the rights of the Commissioners; but, on the other hand, it would be a serious thing to interfere with and prohibit the execution of the works. It would be a serious thing for an order to that effect to be made by a judge who would not ultimately try the case. Of course, if by the act of the defendants irreparable injury would be done or likely to be done, that might and would demand immediate action on his (Mr. Justice Murphy's) part by injunction. But, on the other hand, if any injury resulting from the action of the defendants or either party would not be of an irreparable character, compensation could be made for it at the trial when the case came before the Master of the Rolls or the Vice-Chancellor.

Mr. White: Of course, the question of convenience or inconvenience is a serious one.

Mr. Justice Murphy: It must be irreparable injury.

Mr. White: What we proposed to the defendants was that they should enter into an undertaking to keep us harmless and indemnified against all actions and demands instituted or made on behalf of any person, firm, or corporation in respect of loss damage, or injury sustained, or alleged to be sustained, in consequence of the opening or breaking up of any such streets or roads as aforesaid; and, further, that the defendants should in any such action be joined as third or indemnity party within the meaning of the rule of the court. Defendants declined to enter into that agreement, and they entered upon the roads in, as we allege, the capacity of trespassers, and proceeded to dig trenches in them.

Mr. O'Shaughnessy: And your men by violence prevented us.

Mr. White: Men were sent to throw the earth back into the trenches. The defendants said that the Blackrock and Kingstown Commissioners consented to the putting down of the cables and

Digitized by Google

wires; but that could not settle the question of law raised in this case. Besides, it was not known what inducements had been held out to the Kingstown and Blackrock Commissioners to procure their acquiescence and consent. The Commissioners relied, as they had a right to rely, upon their contract that nothing shall be put up in their township but the overhead wires. If the defendants had not taken sufficient powers by their Act they should go back to Parliament again, but at present they were not in a position, for they had not the power to enter upon and break up the roads under the control of the Commissioners On the present motion it was only necessary for his Lordship to be satisfied that there was a case to be tried. The most serious accidents to life and property might result if underground cables and wires were laid down, and if the defendants persevered with the work they might, and no doubt would, do acts which would be entirely irreparable. The balance of convenience was, therefore on the side of the Commissioners, and in favour of an injunction, and even the test of irreparable injury was, he submitted, in their favour. An injunction, he submitted, should be granted.

Mr. Sullivan, Q C., replied on behalf of the tramway company, and said in applications of this kind for an interlocutory injunction, an element of great importance, and to which great weight was always given, was the extent of the loss, damage, or inconvenience which might be caused by the granting of the injunction He was surprised to hear it stated on the other side that loss to an enormous extent would not result from the granting of this injunction. In one of the affidavits it was stated that if the Court granted the injunction against the defendant company it would render the Act of 1893 a complete nullity, preventing the opening of the line for traffic, and occasioning an enormous loss on the company and the contractors. He charged the statements made in the plaintiffs' affidavits as not being made *bonâ fide* This serious loss and damage must result beyond doubt If the injunction were not granted the line could be completed by October 1, and the roadway restored to its ordinary condition. But at present 200 men had been flung out of employment, and would be kept out of employment until January or November if this application were granted. The company had spent already on these works £130 000. In his opinion that was very strong evidence that great loss and inconvenience would result from the granting of this application The line had been completed through Kingstown, and there never was a suggestion of any difficulty or danger while that work was being done, or likely to result after it was completed. The result was this, that the feeders had been laid down in every part of the line, except in the Pembroke township, and the line could not be completed in its entirety if this injunction were allowed to go . Without the construction and laying down of the feeders, the system could not be worked, and, if his Lordship granted the application, it would paralyse the line for at least two or three months, at great loss and to the serious inconvenience of the public, because the roadway could not be properly laid until the work was finished, and it could be finished if now allowed to go on within the time he had mentioned. There were grave and serious questions of law involved in the case. They said the acts complained of were necessary to the exercise of the statutory powers given to them. The powers given to them were to construct an electrical tramway by the system of overhead wires, and this power could not be properly exercised without laying down these feeders in the manner he had described. The feeders were of such a size, weight, and capacity that it would be impossible to carry them overhead. They were an integral part of the system mentioned in the Act, and without them the line would be inoperative. There was no human probability of any serious damage being occasioned by these works, and if any did occur the company were willing to take the fullest responsibility for it, and they would be a good mark for any pecuniary damages that might be awarded against them. These underground wires were properly insulated and armoured and could not be broken into. They were as harmless when laid in position as an ordinary bar of iron, and to say that a pick or crowbar coming into contact with one of them would entail serious consequences to the workman was absurd There were 300 lines of this sort laid in the United Kingdom, and it never occurred to anyone across the water that any danger would occur from their use Five and a half miles of this line had been laid from Dalkey through Kingstown and Blackrock, and it never occurred to the people of these townships that there was any danger. He asked the Court to refuse the motion.

Mr. O'Shaughnessy Q C., followed on the same side, and said similar cables to those complained of were laid under the pavement in the principal streets of Dublin for electric lighting, and no complaint had ever been made and no damage had ever been caused Dalkey, Kingstown, and Blackrock townships had also made no complaint. The overhead wires were, in his opinion, unsightly, and it would have been more in the way of common sense if the Pembroke Commissioners had opposed the erection of these than in the laying of the underground wires.

The injunction was refused.

COMPANIES' MEETINGS.

ELECTRIC CONSTRUCTION COMPANY, LIMITED.

The second annual general meeting of this Company was held yesterday at Winchester House, E.C.

The **Chairman** (Sir Daniel Cooper, Bart., G.C.M G.), who presided, said that the report and accounts, if not so satisfactory as they could wish, showed a considerable improvement as compared with those submitted last year, and gave good promise for the future, for the manufacturing profit of the year amounted to £31,814. 12s 7d., against £25,754 10s. 5d last year. The net profit of £12,091. 10s. 3d the directors recommended should be appropriated in payment of the full preference dividend, and the balance of £10,134. 15s. 10d carried forward to the credit of next year's account. The profit had all been fairly and hardly earned, and might properly be applied in payment of a dividend on the ordinary shares, but their available capital was barely adequate for the development of the business, and at the same time to do justice to the debentures and shares in other companies inherited as a legacy from the old corporation. That was the sole reason that moved the directors to the conclusion that it would be for the advantage of the Company, and ultimately in the interest of the shareholders, to make no distribution of dividend at present. Some of the Board were amongst the largest shareholders, and no doubt would be greatly pleased to have a dividend, not merely for the sake of the money, but from the credit arising from the paying of a dividend, but they were satisfied that in the long run it would be more to their credit as directors and advantage as shareholders to build up the business on broad, solid foundations. They asked the shareholders to have a little further patience, feeling confident that their forbearance would meet a due reward. The accounts were clear and explicit, but he would invite attention to those items which specially indicated the position and progress of the Company. The profit and loss account showed working expenses reduced fully £2 000. Their hopes of further improvement were in the direction of getting better results from their expenditure The depreciation account had been credited with £5,000 out of revenue, as compared with £3,000 last year. After some experience they hoped to reduce this sum. On the credit side of the account, the gross manufacturing profit amounted to £31,814 12s 7d , over £6,000 more than last year Such profits were strong evidence of the remunerative character of the business in which the Company was engaged. Coming to the balance sheet, on the assets side of the account £1 940 2s 6d. had been added to the property account for additions to plant and buildings, which would enable them to turn out more work. The old property of the Company in Commercial road, Wolverhampton, had been sold, and the price obtained for the property (£2,500) had been handed to the trustees of the first mortgage debentures and invested for the benefit of the debenture-holders On the account "shares and debentures in other companies" the total debit remained practically the same as last year. He believed that as the various undertakings developed the amount at debit of the account would be fully realised The installations completed during the year had been entirely successful, and confirmed the reputation of the Company for first-class work. The Chairman then referred to work being carried on at Clerkenwell and Hartlepool (details of which were given in the directors' report published in our last issue) The directors were pleased to be able to report that their relations with the workmen at Bushbury were of a highly satisfactory character. Now that the works were completely organised under the supervision of their manager, Mr. Blackburn, and the most competent staff that could be had, the out-turn of work was increasing and its quality maintained their high reputation for skill and workmanship. The best evidence of this was that they were full of orders for the next six months. In these circumstances the directors had now intimated a moderate advance in prices, such as was fully justified by the advance in materials and the improved prospects of trade. With electrical plant it would be found even more certain than in the case of other machinery that the best was the cheapest. The prices would compare with those of other makers of first class machinery, but they declined to sacrifice quality to cheapness. Much advantage could not be expected from the new prices during the first half of the year; the benefit would accrue later on. The general position of the Company had materially improved during the year, and he fully expected to be able to submit next year a report and accounts showing still greater improvement. Speaking as one largely interested in the Company he had now more confidence in its management and in the profitable character of its business than at any previous period of its existence.

The **Chairman** then formally moved the adoption of the directors' report and accounts which was seconded by **Mr. J. W. Barclay** (deputy-chairman) and carried unanimously.

In reply to a shareholder it was stated that the Hartlepool tramways would be worked on the overhead system.

The retiring directors (Messrs. J. W. Barclay and J. I. Courtenay) and the auditors (Messrs J. Meeston and Co.) were re-elected, and the meeting closed with the usual votes of thanks.

BRIGHTON AND ROTTINGDEAN SEASHORE ELECTRIC TRAMROAD COMPANY.

A meeting of the directors and shareholders of this Company was held last Friday at the offices, Madeira-road, Brighton.

Mr. E. O. Bleackley (chairman of directors) presided, and explained why the line would not be opened this season, as they had confidently anticipated it would be when they last met there. As usual, the cause of the delay was the Corporation of Brighton, in which body there was unfortunately a strong party who had done everything in their power from the very beginning to damage and thwart the undertaking, and delay its completion in every possible way.

The **Chairman** moved and **Mr. J. J. Clark** seconded, a resolution authorising the issue of debentures, and the motion was carried unanimously, after complaints had been made that the Town Council had insisted on another diversion of the line.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Alexandria.—The municipal authorities of Alexandria, Egypt, invite applications by October 1, 1895 for the concession of the tramway lines from St. Catherine Place, through the outer boulevards, to the projected abattoirs at Mex, with a branch line. Security £E1,000.

Paris.—The Direction Générale des Postes et Télégraphes invite tenders by September 16 for making two air-conduits for the pneumatic telegraph service. The Cahier des Charges may be seen at rue de Grenelle, No. 103 (division du matériel et de l'exploitation électrique, 3ME bureau).

Braila.—The Municipal Authorities of Braila, Roumania, invite tenders by October 2 for the construction and working of a system of electric tramways in the city. Provisional security, 10,000f This contract was originally fixed for July 29. Tenders are further invited by the Municipal Authorities of Braila for the lighting of the city by electricity or by electricity and gas. Provisional security 10,000f.

Huddersfield.—Tenders are wanted for the lighting by electricity of the boot and shoe and confectionery departments, reading-room, library, etc., in John-street and Albion-street, Huddersfield, for the Huddersfield Industrial Society, Limited. Specification may be obtained at the office of Mr. J. Berry, architect, 9 Queen-street, Huddersfield Tenders to be delivered at the society's office, Buxton-road, by 4 p m. on 16th inst.

Harrogate.—The Corporation of Harrogate invite tenders for wiring the new Montpellier Baths for electric lighting. Specifications and full particulars may be obtained of Messrs. Baggallay and Bristowe, architects, 66, Conduit-street, London, W., on payment of £1 1s., returnable on receipt of bona fide tender. Sealed tenders, endorsed "Tender for Wiring New Baths," are to be sent to the town clerk, Municipal Offices, Harrogate, by September 30.

Chepping Wycombe (Bucks.).—The Urban Sanitary Authority for this borough are prepared to receive tenders from public companies for working the electric order obtained by them within the borough for a term of years and upon approved conditions. Tenders are to be delivered by noon on October 14 next, at the office of the town clerk, High Wycombe, where a copy of the electric order may be seen and further particulars obtained. The Authority do not bind themselves to accept any tender.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

Shoreditch.—The Shoreditch Vestry invite tenders for—Section A—insulated electric mains; Section B—conduits and drawing in boxes; to be laid in the parish of Shoreditch. Specification, with form of tender, can be obtained from the consulting engineers, Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster, on payment of three guineas, which will be returned on receipt of a bona fide tender. Tenders, endorsed "Tenders for Electrical Mains," to be sent by 17th September to Mr. H. Mansfield Robinson, vestry clerk and solicitor, Town Hall, Old-street, E.C.

Gravesend.—Tenders are requested for the supplying of a telephone, and providing, delivering, and fixing, etc., of the necessary poles, wires, instruments, and plant at regulation distance of a specified description, from the sanatorium to the office of the sanitary inspector and the police station, for the Town Council. Tenderers are also requested to specify an amount per annum at which they would maintain the communication. Further particulars can be obtained of the sanitary inspector, Town Hall. Tenders, marked "Sanatorium Telephone," must be delivered to Mr. Chas. E. Hatten, town clerk, Gravesend, by September 20.

London, E C.—Tenders are requested for the following, for the Shoreditch Vestry: (Section A) insulated electric mains; (B) conduits and drawing-in boxes, to be laid in the parish of Shoreditch. Specification, with form of tender, can be obtained from the consulting engineers, Messrs. Kincaid, Waller, and Manville, 29 Great George-street, Westminster, on payment of £3 3s., to be returned on receipt of a bona fide tender. Trades union rates of wages and hours of labour to be observed. Sealed tenders, endorsed "Tenders for Electrical Mains," to be sent by 4 p m. on 17th inst. to Mr. H. Mansfield Robinson, vestry clerk, Town Hall, Old-street, E C.

Stafford.—The committee of the Staffordshire County Infirmary invite tenders for wiring and fitting the infirmary for electric light. Tenders, sealed and addressed to the Secretary, Staffordshire County Infirmary, Stafford, and endorsed "Tender for Electric Lighting," must be received by him not later than noon on September 14. Copies of the specification, with form of tender attached, can be obtained from the secretary on payment of £1, which will be returned on receipt of a bona fide tender; and plans may be seen on or after Monday, September 2, at the infirmary, or at the offices of the engineers, Messrs. Kincaid, Waller, and Manville, 29, Great George street, London, S W.

Dewsbury.—The Corporation invite tenders for wiring the Public Baths and Library. Forms of tender and copies of specification may be obtained from the borough electrical engineer, Electricity Offices, Bradford-road, Dewsbury, on payment of £1. 1s., which will be returned on receipt of a bona fide tender, together with the specification. Plans may be seen at the office of the borough electrical engineer, Bradford-road, Dewsbury, from whom any further information can be obtained. Sealed tenders must be sent to Mr. E Mawdesley town clerk endorsed "Electric Lighting, Public Baths and Library," not later than 12 noon on Saturday, the 21st inst.

Dundalk.—The Dundalk Town Commissioners invite tenders for erection of an electric lighting installation for the purpose of lighting the town by electricity on or about July 1, 1896, reserving to themselves the right of taking over the plant at the end of a term of years—this term to be stated in the tenders. The successful contractor to have the right of supplying private consumers, while the Commissioners will pay a fixed sum yearly for the town lighting—this sum to be stated in the tender also. The Commissioners have obtained a license from the Board of Trade for supplying electric lighting. Tenders will be received by Mr. Edward Farrar, town clerk, Town Hall, Dundalk, up to October 7.

Queenstown (Ireland).—Tenders are invited by the Queenstown Town Commissioners for the lighting of Queenstown by electricity (private as well as public) as per report and specification of Mr. R. Hammond, M.I.E.E., Ormond House, London. Tenders are also invited as follows: the contractor to provide the capital for the due erection of the works and maintenance thereof as per above plans and specifications, on being guaranteed the public lighting, and a stipulated number of private lights (to be agreed upon), the Commissioners having the right to purchase within a specified period. Plans and specifications are deposited at the Hall, Queenstown, and can be inspected there between 11 and 2. Tenders must be lodged with the town clerk, Queenstown, marked "Tender for Electric Lighting," by 2 p.m. on September 16. Further particulars and conditions to be had on application to Mr. James Ahern, town clerk, Queenstown.

Belfast.—Tenders are invited for the supply and erection of two direct coupled steam-engines and dynamos, battery of accumulators, main switchboard, and installation of about 232 incandescent lamps, complete, for the lighting of Belfast Lunatic Asylum, for the Commissioners for the Control of Lunatic Asylums. Tenders should be sent in a sealed envelope, endorsed outside "Tender for Works for Lighting Purdysburn Asylum," and addressed to the secretary, Board of Control, Custom House, Dublin, and accompanied by a separate sealed envelope, similarly addressed and endorsed, containing the detailed estimate. Forms of tender will be issued on application to the office of the Board of Control of Lunatic Asylums, Custom House, Dublin, on deposit of £1. which will be returned to all persons who have sent in bona fide tenders Plans and specification can be seen at the office of Mr. O A H. M'Cowen, Chapel-lane, Belfast. Tenders by 10 a m. on 28th inst.

Manchester.—Tenders are invited for the execution of the following works, for the Manchester Corporation—(Contract 2) laying a system of underground telephone pipes, with brick inspection pits, service boxes, and other appurtenant works in the following streets: route 6—Little Peter-street, Chester-road, Hulme Hall-road, to a point adjoining the Ship Canal. Laying a system of underground telephone pipes with brick inspection pits, service boxes, and other appurtenanant works in the following streets (Contract 3)—viz.: route 1—Dickenson street, South-street, Jackson's-row, Deansgate, Atkinson-street, Byrom-street, Camp-street, Charles-street; route 2—Dickenson-street, George-street, Nicholas-street Booth-street, Tib lane, Cross street, South King-street, Deansgate, Lower King-street, Ridgfield, John Dalton-street; route 2A—Pall-mall, Moult-street, Bank-street, Half Moon-street; route 2B—Bank-street, Exchange-street, St. Mary's-gate, Blackfriars-street, Parsonage; route 3—Faulkner-street, Charlotte street, Back George-street; route 3A—Charlotte-street, Fountain street, Marble-street, High street, Cannon-street, Hodson's-square; route 3B—High street, Nicholas croft, Bradshaw-street, Cross-street, Balloon-street, Holgate-street, Corporation-street, Mark-lane. Drawings may be seen, and copies of specification, bills of quantities, and forms of tender for each contract may be obtained on application at the city surveyor's office, Town Hall, Manchester, on September 9, on payment of £2. 2s. and £5. 5s. respectively, which sums will be refunded on the return of the documents and the receipt of bona fide tenders. Sealed tenders, enclosed in the official envelopes, to be sent in by 5 p.m. on September 17. The Corporation also invite tenders for the supply of about 15 tons of copper strip. Specifications and forms of tender can be obtained on application (in writing only) to Mr. C. Nickson, superintendent, Gas Department, Town Hall, Manchester. Tenders to be sent in not later than 10 a m. on the 20th inst.

RESULTS OF TENDERS.

Witton Gilbert (Durham).—The Parish Council have accepted Messrs. Crompton's and Charlaw Colliery Company's tenders for lighting the whole parish of Witton Gilbert by electricity at 33s. per lamp, 4s. 6d. a lamp cheaper than by gas.

Worcester.—The City Council have accepted the Brush Company's offer to supply and fix two 36-kilowatt transformers for the waterworks motors in lieu of the 30-kilowatt transformers originally supplied at £25 on condition that the company give a written guarantee that the larger transformers will be sufficient for the purpose, and that they will maintain them in good working order for two years without charge.

Ayr.—The following tenders have been received by the Police Commissioners for wiring the municipal buildings, public library, and police offices, and furnishing the necessary fittings—viz.:

BUSINESS NOTES.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3 026.

Personal.—Mr. E. G. Pink has been appointed by the Ayr Town Council electrical engineer at a salary of £200.

Nerden (Lancs.).—The question of introducing the electric light was raised at the last District Council meeting.

Middleton.—The Town Council have decided to memorialise the Board of Trade for a provisional order empowering the Council to adopt the Electric Lighting Act for the borough.

Suter Hartmann and Rahtjen's Composition Company, Limited.—We are informed that Hartmann's paint for iron and wood has been adopted for recoating the electric light posts in the city of London.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 8th inst. amounted to £1,324, as compared with £1,054 in the corresponding week of last year, being an increase of £270.

Walsall.—The works for the supply of electric light to the town are now in a forward state, and it is anticipated that the new illuminant, for which over 1,000 lights have already been prepared, will be ready at the commencement of next month.

Electrical Instruments.—We have received a copy of the catalogue of electrical testing and measuring instruments manufactured by Mr. Robt. W. Paul, of Hatton-garden, London. It is very complete, well illustrated, well printed, and well indexed.

Barnet.—Mr. Bampfield has given notice that at the next meeting of the Urban District Council he will move that the Council consider in what way the question of electric light can be dealt with so as to satisfy the requirements of the provisional order.

Eastbourne.—The Eastbourne Electric Light Company having requested permission to extend their mains in Terminus-road and South-street, the Town Council have resolved that the application be granted subject to the works being carried out in October next.

Runcorn.—The Rev. Dr. Garcaldi has given notice that at the next Urban Council meeting he will move that it is in the interest of the ratepayers of Runcorn that the electric light be introduced in the town, and that a committee be appointed to carefully consider the subject.

Burton-on-Trent.—The report of the Gas and Electric Light Committee of the Town Council states that the manager of the gasworks has been instructed to report to the committee as to the desirability of lighting the streets with the electric light where the mains are laid for electricity.

City and South London Railway.—The returns for the week ended September 8 were £839, compared with £840 for the corresponding period of 1894, being a decrease of £1. The total receipts for the half-year 1895 are £8,509, compared with £8,576 for the corresponding period of 1894, being a decrease of £67.

Longton (Staffs.).—The Mayor, with other gentlemen, has been appointed a sub-committee to prepare the necessary details for the provisional order with reference to the extension and working of the tramways in the borough, and to conduct the negotiations for the working of the same, with full power to deal with the matter.

Ayr.—During the year there has been borrowed by the burgh for electric lighting £3,750, and of that there has been spent for the cost of the provisional order, site, and other expenses, £2,917, leaving £832 still at credit. During the present year a considerable sum will be required, and provision has already been made to borrow the requisite amount.

Bury.—At the last meeting of the Town Council Alderman Brierley moved the adoption of the Electric Lighting Committee's minutes, which consisted of the passing of the accounts. The proposition having been seconded, Councillor W Sykes thought that they might have considered the question of electric lighting. The Mayor: We are not taking any harm by waiting.

Altrincham.—Mr. Newton moved at the Urban Council meeting that the Highways Committee obtain tenders for lighting their offices and also the Market-place with electricity and submit the same with their recommendation to the next meeting of the Council. Mr. Boyd seconded the motion. Mr. J. Drinkwater said he thought that the company intended to light the Market-place for nothing.

East Grinstead (Sussex).—The General Purposes Committee of the Urban Council have reported that they could not at present recommend the Council to bind themselves in any way in the matter of the electric light, but they suggest that Messrs. Owen, Pike, and Co. should be informed of the number of public lamps. A letter has been received from Mr. W. Howard Tasker offering his services as electrical engineer.

Swansea.—The scheme for lighting the main streets of Swansea by electricity, and at the same time using the plant for the purpose of destroying the town refuse, is now complete. The Corporation Committee have finally considered the report, which will be presented to the Corporation at its next meeting for consideration and adoption. The work, which is to be turned out under the guidance of Mr. Manville, will cost about £50,000.

Liverpool.—The Waterloo District Council have received the following communication: "Liverpool Gas Fittings Company, Limited, 126A, Duke street. Liverpool, August 24, 1895. To the Chairman, the Waterloo Local Board, Waterloo. Dear Sir,—Having heard that you contemplate installing the electric light at your Town Hall, we shall be very glad to submit a tender for same if you will kindly forward us the specification.—Yours faithfully, JOHN HAYNES."

Cork.—Mr. O'Toole has reported to the Waterworks Committee of the Corporation that he had gone into the question of lighting the waterworks with electricity, and after allowing for the upkeep of plant, etc., there would be a saving each year sufficient to pay principle and interest of the plant in at most five years, and after that period probably the saving would be £50 a year. It has been decided to ask a Dublin firm to supply a specification of the plant that would be required.

Weybridge.—There was a long discussion at the last meeting of the Urban District Council on the question whether the town should be lighted by gas, oil, or electricity. The chairman and a committee had entered into a contract with the gas company, but it was argued that they had acted *ultra vires*, and a strong preference was expressed for the electric light. Ultimately, however, as a recission of the contract might probably result in legal proceedings, nothing was done.

Eccles.—The Town Hall, Tramways, and Electric Lighting Committee of the Town Council have reported that a circular was received from the Town and Village Electric Light and Power Company, Limited, in which it was stated that the company were prepared to erect, on land owned by the Corporation, a complete installation for public lighting by electricity, lay mains for private lighting, etc. The communication was ordered to be passed on to the consulting electrical engineer.

Thames Valley Launch Company, Limited.—This Company has been registered, with a capital of £10,000 in £5 shares. Object: to acquire the business of a launch and boat builder, electrical and general engineer, etc, as now carried on by the Thames Valley Launch Company at Weybridge and elsewhere; to enter into an agreement with W. R. Edwards, and to carry on the above business in all its branches. The directors are S F. Beevor and W. R Edwards. Registered office: Riverside Works, Weybridge, Surrey.

Bradford.—In connection with the oil-gas experiments, the Gas and Electricity Committee of the Corporation recommend that "after full trial of the apparatus and process patented by Dr. Dvorkovitz for the enrichment of gas by oil, and after careful consideration of reports by Mr. Lewis T. Wright, the expert called in to advise on the matter, the committee find that the experiment has not proved such a success as to warrant the adoption of the system by the Corporation, and that the Council be accordingly recommended to abandon the scheme."

Westralian Electric Lighting Supply Company, Limited.—This Company has been registered with a capital of £80 000 in £1 shares. Object: to adopt and carry into effect an agreement made September 3 between Westralia, Limited, of the one part and this Company of the other part; to generate, store and distribute electricity or any other agency for the purpose of lighting public or private buildings factories, mines, public streets, omnibuses and other vehicles, lighthouses, railways, and for other purposes, and to act as electricians and electrical engineers generally in West Australia or any other part of the world.

Digitized by Google

Halstead (Essex).—A letter having been read from the manager of the gas company at the Urban Council meeting with reference to the price of gas, in which he stated the directors did not see their way clear to make any reduction at present, Mr. Clark said a temporary agreement might be come to for the present with the company, and in the meantime enquiries might be made in various towns in the neighbourhood, and also as to the probable cost of substituting electricity. He referred to a case at Thetford (Norfolk), where the cost of starting the electric light was only £3,000. The question was referred to the Lighting Committee

Aberdeen—The Watching and Lighting Committee of the Aberdeen Town Council have discussed a suggestion, emanating from Mr Blackman, electrical engineer to the Corporation, to provide additional electric lighting in the streets. Mr. Blackman proposed overhead lights, suspended above the middle of the streets by a wire stretched between standards on either side of the thoroughfares. On the proposal of Mr. Young it was agreed to recommend the Council to place two such lights in Broad-street and two in Bridge street or Market-street. Should these give satisfaction, the system may be adopted in other thoroughfares.

Mevagissey (Cornwall).—A poll having resulted in the adoption of the Lighting Act, and as several committees had enquired into the working and cost of the several lights, and the electric had proved to be the cheapest, the Parish Council have adopted the following resolution: "Provided an electric company be formed within a reasonable time so as to admit of lighting the streets during the coming winter, this Council will offer such company the sum of £40 for lighting 30 lamps 1,500 hours in the ensuing 12 months; if any further lights be required it be paid for at the same rate. and something definite to be reported to the next monthly meeting"

Whitby.—Owing to the former contracts of the Local Board with the Whitby Gas Company being invalid, the clerk to the Urban Council said at the last meeting that it would be necessary to impose a penalty in future contracts. Mr. R. Harrowing said there was no reason why the company should squeeze them as they did, and his reason in suggesting that a penalty be inserted was to show the company that they might take some means, either by making gas of their own or by going in for the electric light, to thwart their designs. It was a shame that they should have to pay such a large sum, when larger towns—such as York—were only paying one half. He moved that the sum be £400. The motion was carried unanimously.

Plymouth.—The Corporation Tramways Committee's last minutes contained the following recommendations: "That the borough surveyor visit Bristol and Walsall, and inspect the tramway systems in those places respectively, and that he report to the committee thereupon, and as to the additional cost which would be involved in laying the Ebrington-street lines on the electrical principles adopted in the towns before mentioned." "That the tramway manager be allowed the sum of £15 for the purpose of visiting Glasgow, Birmingham, London, Liverpool, Leeds, and such other places as he may deem advisable, with a view to bringing himself in touch with the latest developments of tramway management" The minutes were adopted.

Hanley.—The Electric Lighting Sub Committee of the Town Council have recommended that the two assistant electrical engineers, Mr. Cowell and Mr. Sutherland, be appointed joint electrical engineers and managers of the electricity works under the general direction of the borough engineer, at salaries of £150 each per annum, commencing on September 1. The proposal was only to last till the extended installation was carried out The General Purposes Committee have recommended that the corporate common seal be affixed to an agreement between the Hanley Corporation and the North Staffordshire Tramways Company with respect to electric traction by means of overhead wires, and to the powers of purchase by the Corporation not being exercised for the term of 21 years. This has been approved.

Stafford.—The Electric Lighting Committee of the Town Council have instructed the engineer to have the boilers and steam-pipes, and also the steam-pipes in the engine-room covered with a non-conducting composition and to place the work with Messrs. F. Leroy and Co, of Lower Broughton, Manchester. The engineer having reported that he hoped to be able to supply the electric current for public use by September 25, the committee have appointed the chairman, vice-chairman. and Councillors Bennett, Flamank, and Wormal as a sub-committee to make all necessary arrangements in connection with the opening ceremony, and the committee asked to be empowered to spend not more than £20 on the occasion. The committee recommend that the electric cables be extended to the infirmary buildings.

Delaware Hard Fibre Company.—The following appears in the *Electrical World* New York, of August 24: "A flourishing business is reported by the Delaware Hard Fibre Company, of Wilmington, Delaware, necessitating the operation of the works day and night, notwithstanding the fact that the size of the plant has been doubled. The company has secured the contract for furnishing the General Electric Company (U S.A.) with fibre, and this work alone is sufficient to give employment to quite a large number of hands." This is supplemented by a report from Mr. Burns, to whom the company has entrusted the management of its business in all parts of the world except the North American Continent, who states that the progress of business during 1895 shows a gratifying and unexpected increase over 1894.

Rugeley.—Mr. Gilbert, at the Urban Council meeting, submitted a statement on behalf of the Lighting Committee, explaining that the gas company were willing to grant a reduction of 1s. per lamp on all the small lamps. and the committee recommended the acceptance of this offer for the coming season only. They asked the Council for power to take into consideration the question of lighting the streets by electricity, as they had already received two tenders from leading electrical firms which compared very favourably with the cost of lighting by gas, and several applications from electrical engineers asking to be allowed to submit schemes. The committee felt that it was too late to do anything in the matter this season, but if their recommendation was adopted they suggested that it might be taken up next year. The report was carried.

Carnarvon—The National Telephone Company have written to the Harbour Trust stating that if sufficient encouragement were given they proposed to open up Carnarvon and Bangor for telephonic communication by establishing telephone exchanges in each town, and connecting the offices or residences of subscribers thereto. When these exchanges were opened the company saw no reason to doubt that the Government (Post Office Department) would continue the trunk lines through from Llandudno, and so enable subscribers to have telephonic communication throughout their system It was suggested that such a communication would prove of great advantage to the harbour. Mr. Lloyd Carter moved, and Mr. C. A. Jones seconded, that the Trust should sign an agreement for one year with the telephone company. After some discussion as to the scale of charges, which was considered excessive, the proposal was unanimously agreed to.

Cheltenham.—Mr. Norman, in introducing the minutes of the Public Lighting Committee, has mentioned that the gas lights had shown a tendency to fall below the standard of 17 candles. With regard to the electric light, the month had been one of unbroken success. Having referred to the proposed purchase of transformers and other minor matters, he passed on to consider the question of lighting the principal streets, and also favoured a memorial sent in by Mr. Selim Smith that the new light should be taken up above Cambray. He believed that a striking effect would result from arc lamps amongst the foliage in the Promenade. Mr. Norman then entered at some length into the question of cost, of which he took a hopeful view. Mr. Margrett moved an amendment to the effect that the electric light should not stop at the Royal Hotel, but should be carried up to the Belle Vue Hotel. This was seconded by Mr. Dimmer, and accepted by the committee.

Kirkby Lonsdale.—The Chairman said, at the last Urban Council meeting, that he had had some talk with representatives of the National Telephone Company at Kendal respecting the inclusion of Kirkby Lonsdale in the district. He asked the secretary to write down his suggestions, with remarks as to the advantages, cost, etc This communication he had received, and sent to some of the leading tradesmen of the town to get their advice, and to see whether the service would be of utility to the town and district. The chairman said the annual subscription was about £8. This would ensure free telephonic communication to all towns within the district, including Kendal, Windermere, and the intermediate places. Outside the district there would be trunk lines, and towns such as Lancaster would be 3d. extra, Preston 6d., etc. It was necessary to have 10 subscribers before an exchange could be opened. He hoped the tradesmen in the town would consider the matter, and some of the local gentry might become subscribers as well.

Hastings.—The Roads Committee of the Town Council have received from the secretary of the Hastings and St. Leonards Electric Light Company, Limited, notice of the intention of the company to extend their main from a point opposite the junction of South-terrace with Queen's-road, across the road to the box opposite 36, Queen's-road, thence to 57, Queen's road, a distance of 170 yards. A high-tension cable was intended to be carried in 2¼in. wrought-iron pipes, with socket joints, and a low-tension cable in 2¾in. wrought-iron pipes. Both pipes were to be laid under the pavement about 2ft. from the kerb, at a depth of 2ft. A cast-iron box, marked "b" on the plan, was to be laid in 4½in. brickwork, the size of the same being 2ft. by 18in., pavement frames and covers being provided in connection with the same. The committee recommended that the plan be approved, subject to the works being carried out to the satisfaction of the borough engineer, and to the company undertaking not to remove the cover of the box, except between the hours of 10 p.m and 9 a.m., unless in case of actual emergency. The report was adopted.

New Malden (Surrey).—With reference to the communication from the Kingston Corporation as to supplying electric current to Coombe, the Clerk said, at the last District Council meeting, that he had not yet had time to prepare a report as to the future legal position of the Council in regard to the matter. The matter would therefore have to stand over for another month. Mr. Monro said Mr. Willis was engaged in altering his house, and desired to have an electric installation at the same time. It was a pity there would have to be another month's delay. Mr. Willis would like to have the permission of the Council to have the installation as soon as possible. He (Mr. Monro) did not think the Council ought to stand in the way of the spread of the electric light in this district. It was usual in cases where an outside authority wished to supply the current for the local authority to stipulate that it should be allowed to take over such part of the plant as lay in its own district at any time it pleased and at cost price (or less), without any allowance for goodwill or for the fact that the plant was part of a going concern. The discussion was adjourned until the next meeting.

Romford.—Mr. Westgate having given notice to move that the Urban District Council should take such steps as are necessary to obtain the powers to use the electric light for the parish, Mr.

Digitized by Google

Smith suggested that the consideration of the matter should be deferred to the next meeting. The Chairman did not wish to enter into any discussion as to the merits of the proposal, although he differed somewhat from the opinion of the proposer. He thought that if they went to the Board of Trade for a provisional order, to exclude any other company, they would not get it. If any authority came forward and asked permission to establish works simply with the object of excluding any other company, it was a policy which he thought the Board of Trade would not approve of. It would be a selfish policy unless they could show a *bonâ fide* intention to carry out the work in one or two years. Mr. Westgate thought it possible that they might get the work carried out within two years. The cost of obtaining the provisional order would not exceed £100. Mr. Smith: I have never known one cost so little. Mr. Westgate: I have not watched the question. Mr. Smith: I have, and I have known them to cost £600.

Kendal.—The surveyor to the Westmorland County Council has reported that the National Telephone Company have applied to build a line from Kendal to Ambleside, to pass through Burnside and along Winter-lane, and to come on to the main road from Kendal to Ambleside about half a mile south of the Staveley level crossing over the railway. In the length to the junction with Over Staveley, at Gawen Bridge, rather short of one mile, they would erect 29 poles. In the village of Staveley the surveyor could not see that it would be advisable to allow any poles to be erected, but, after leaving the village, he saw no objection either in this township or Hugill to erect about 68 poles. The line would then pass through the Windermere urban district as far as Troutbeck Bridge, and continue through Troutbeck to Holbeck Bridge. There would be difficulty here, as it would not be wise to allow the poles to be placed on the west side of the road, as the parapet is quite narrow enough, but if the company could arrange their poles on the east side he could see no objection. There should be no interference with the traffic, and a charge of one shilling per pole per annum should be paid. The committee have resolved that the National Telephone Company be allowed to erect poles on the main road, as set out in the report, to be placed under the direction of the county surveyor.

Halifax.—The Town Council are considering various proposals for tramways with a view to coming to a decision as to the system of traction to be adopted, and also whether the lines shall be worked by private companies or by the town. We understand that the Corporation intend placing six arc lamps, each with a power of 1,500 candles, between Old Market and Cow green, the intervening route being Crown and Silver streets. These illuminants will hang from the curved top of ornamental iron standards, reared several feet higher than the ordinary street lamp. Messrs. Macfarlane, of Glasgow, are supplying these; one is now in position at the Commercial Bank corner. Other of the main streets are to be so lighted in turn. The Yorkshire Penny Bank is the most notable recent connection with the electricity mains. In pursuance of the Corporation's decision, these mains are being extended along Skircoat-road towards Heath, in which district rather an extensive application has been made for the light. At the electricity works, at the bottom of Foundry-street the foundations are being prepared to receive the new combined engine and dynamo, of 600 h.p., which Messrs Pollit and Wigzell, of Sowerby Bridge, are making, and hope to have ready next month. The new infirmary is to be lighted by electricity from a plant to be laid on the premises.

Alsager (Stoke-on-Trent).—A meeting of ratepayers has been held to consider the advisability of adopting some system of street-lighting. The circular issued by the District Council convening the meeting laid the cost of gas and electric lighting before the ratepayers and showed that the former would cost £142 per annum, or an increase in the rates of 3½d. in the £. These figures were obtained from estimates provided by the Kidsgrove Gas Company, which has mains laid in Alsager for private supply. A scheme of electric lighting prepared for the Council by Mr G. R Peers, A.I.E.E., placed the cost of an installation for 1,200 lamps of 8 c.p. alight at one time at £4,000, including 40 street lamps. The annual cost of maintenance would be £618, while the revenue expected from 1,500 lights fixed would be £700, leaving a profit of £82, or no increase in the rates. The gas company was well represented at the meeting, and during the week two circulars had been issued trying to show that electric lighting was a very risky venture. The meeting decided that the streets should be lighted, and Mr. Richmond (a councillor, and interested in the gas company) addressed those present. When the *pros* and *cons.* of gas-lighting had been exhausted, Mr. Peers was called upon to address the meeting and was asked several questions relating to electric lighting which he satisfactorily answered. Eventually the meeting was adjourned for 12 months.

Sheffield.—At the meeting of the Parliamentary Committee of the City Council the following letter from the Sheffield Tramways Company to the town clerk was read and ordered to be entered on the minutes: "Dear Sir,—My directors desire again to communicate with your Corporation upon the subject of the company's lease of the tramways, which, I may remind you, will expire in July next year, and I am to state that they are willing to negotiate terms for a renewal of the lease, and, if terms are not agreed, I may add that the company will be prepared, in the words of the 47 Section of the Sheffield Tramways Act (1872) upon reasonable terms to the satisfaction of the Board of Trade, to continue to work the tramways." The committee resolved: "That this committee are not prepared at present to report whether or not it is desirable that the Corporation should take over and work the tramway system of the city at the expiration of the leases granted to the Sheffield Tramways Company, but they advise the Council that to enable the Corporation to work the tramways power would have to be obtained by an alteration in the existing Act of Parliament, and that such power would have to be obtained by a Bill in the next session of Parliament, and they also advise that steps should be taken to obtain such power." Certain information obtained by the city surveyor and the city accountant with regard to the result of the working of certain tramways under the management of corporations was laid before the committee, and the consideration thereof adjourned to the next meeting, to be held on Tuesday, October 1 next.

Cheadle (Staffs.).—A special meeting of the Parish Council has been held to discuss the most effective and economical mode of lighting the public streets. The Cheadle Gas Company have hitherto held the contract but the Council took exception to last winter's supply, and in accordance with the Local Government Act of 1894 advertised for tenders. The gas company's tender was to light 60 lamps for the 10 months' period at a charge of £3 per lamp, guaranteeing a light of 16 c. p. in each burner. Mr. Ralph Alcock (Cheadle) was prepared to meet the Council's requirements by the aid of paraffin oil lamps. His tender for a term of seven years would be at the rate of £168 per annum or for one year alone £150. There were several other tenders sent in, but the offer which most impressed the Council was one from Messrs. J. and N. Phillips and Co to light the town by electricity. The firm has a large tape manufactory in the town, and could supply the street lamps from the plant to be used in connection with their own lighting. They were in a position to lay down the necessary fittings and light the town for a period of seven years, at an annual cost of £340. If the contract were extended to 14 years the yearly cost would be reduced to £300 The Council, having carefully considered the tenders, were unanimously agreed that the electric light would be the most satisfactory method of illumination, but they could not lose sight of the fact that to accept Messrs. Phillips's tender would be to slightly increase the lighting rate. It was considered desirable to test the feeling of the ratepayers on the subject, and it was therefore resolved that a parish meeting be convened to see whether the Council should accept Messrs Phillips's tender or otherwise.

Hammersmith.—The Electric Lighting Committee reported, at the last Vestry meeting, that they were called together in consequence of a communication from the chairman of the Governors of the Latymer Foundations, he having received a letter from Messrs. Rollitt and Sons offering, on behalf of a client, the sum of £2,100 for the portion of the land in Fulham Palace-road belonging to the Foundation, for which the Vestry are in treaty for the purposes of the electric lighting order. They very carefully considered the matter and under the circumstances they had, subject to the ratification of the Vestry, offered £2,200 for the land The clerk said that 14 tenders had been received for schemes for the electric installation for public and private lighting. He had also received a telegram from a Glasgow firm stating that their tender would arrive on the following day, and they hoped it would not be too late Mr. Glasier proposed that the tenders already sent in should be initialled, and that the one they had received notice of by telegram should be considered along with the others by the Electric Lighting Committee Mr. Payne seconded. The committee's action was agreed to. The Clerk read a circular letter from the City of London Electric Lighting Company, referring to a recent case in the Court of Appeal, stating that it was intended to convene a meeting to determine upon a course of action with the object of obtaining an amendment of the law that will give reasonable protection to undertakers, and at the same time to secure full compensation to all persons and bodies interested, for all damage caused by the user of any electric light works and they were advised that this object would be attained were a general Act of Parliament passed containing a clause in the form annexed to their letter. A letter had been received from Mr. W. H Trenthand, dated 30th ult, offering his services to advise the Vestry in connection with the electric lighting scheme.

Oxford.—The Lighting Committee reported at the last meeting of the City Council that they were in negotiation with the Oxford Electric Company for a revised and extended system of lighting by electricity, and in order to complete these negotiations they recommended that (if necessary) the existing contract with the company be extended to March 25 next. Mr. C. Underhill stated that the committee had rejected the proposals that had been made by the electric light people, who, he believed, wished to light several fresh streets and to increase the power of the present lights. He maintained that the incandescent gas lighting was not satisfactory for the public streets, and he did not see why the Corporation should pay a single penny for the experiment which the gas company wished to carry out. The committee had no right to reject the proposals of the electric company without coming to the Council, and he would move that the report be referred back, to bring up an amended report setting forth the merits of the two proposals—the electric company and the gas company. Alderman Wilson said he understood that the idea was to give the gas company the same power to furnish the public with an object-lesson of what they could do to compare with the great experiment for which the public had paid a considerable sum to enable the electric light company three years ago to do the same. The electric light company carried out that experiment, and he thought the gas company should carry out theirs. Mr. Brooks said the proposals of the electric lighting company were such as the committee thought they might accept, and the request to extend the contract until next March was to enable them to complete the arrangements. The Town Clerk said the present contract would expire on November 16, and the committee hoped

Digitized by Google

to be able to report before next March. There had been no rejection of proposals from the electric company, but the experiment in Beaumont-street, he believed, had been begun. The report was adopted.

Tunbridge Wells.—A correspondent writes: "Councillors have met and transacted municipal business under difficulties in a sub-tropical atmosphere. The gas ventilators were lighted, but the remedy proved worse than the evil, and the gas was speedily extinguished. The suggestion that the electric light would render the atmosphere of the Great Hall more endurable instantly brought the three gas shareholders on the Council to their feet, but this was only the prelude to the most striking illustration which the gas representatives have yet afforded of their dual capacity. It was the meeting at which the half-yearly rate is made, and the chairman of the Finance Committee, who is also the chairman of the gas company, adopted an unparalleled course in his latest attack on the electric light. Mr. Delves, without the support of a single one of his colleagues, moved an amendment to his committee's report with a view to putting a penny more on the general district rate than the committee considered necessary, inasmuch as the estimates showed that the Council would just tide over the half-year without further burdening the ratepayers. A gentle titter went round the council table as Mr. Delves once more attacked the electric light, which with him occupies the unfortunate position of King Charles's head in Mr. Dick's memorial, and amidst growing impatience Mr. Delves persisted in his single-handed attempt to add an unnecessary penny to the rates, in spite of taunts interjected by his colleagues of his gas interests and humorous references to his past financial predictions, which have also been ludicrously wide of the mark. At first no one seconded Mr. Delves's amendment, and then Mr. Finch did so for the sake of discussion, but declined to vote for it. Not only Mr. Delves's colleagues on his own committee, but the officials, in reply to questions by members, flatly contradicted most of his statements, and the anti-climax was reached when a division was taken, and only the three gas shareholders present voted in the affirmative. Who, by the way, is the member of the Council, more than once alluded to during the sitting, who has been canvassing consumers of electric energy and endeavouring to frighten them into the belief that the current which the Corporation supply is more expensive than the rival commodity of gas, in which he deals?"

Blackburn.—An important suggestion has come before the Gas Committee of the Town Council in the shape of a letter from the secretary of the Blackburn Corporation Tramways Company, Limited, stating that the company had been considering the question of working the Preston New-road and Cemetery sections of the tramways with electric traction, and that Mr. E M. Lacey had prepared a report on the matter, from which it appeared the tramways could be worked cheaper by this method; also stating that the company had not the necessary capital to carry out the scheme, and asking if the Corporation would consider the question of providing the necessary capital, and if so, upon what terms. This matter is now in the hands of a sub-committee. The committee also considered the report of the borough electrical engineer upon the proposed extension of the electric lighting installation to Preston New-road and district, on the high-tension alternating system, together with estimate of capital cost and annual income. It was resolved that the proposed extension be carried out, that it be referred to the sub-committee to have specifications prepared for the plant required, together with estimates, and for that purpose to consult Mr. E. M. Lacey, A.M.I C.E, to obtain tenders and submit the same to a future meeting of the Electric Lighting Committee. Councillor Garsden, in respect of the tenders received for wiring and fittings required for the electric lighting of the Town Hall, asked why it was that, a committee having decided that no tender above a certain sum should be entertained, the sender of one tender above that sum had been asked (with others) to furnish designs for fittings. Councillor J. Law stated that among the tenders was one from a very respectable firm of local tradesmen which was only two or three pounds above the sum specified as the maximum, and he had, after consultation with other members of the committee, taken the liberty of including these local tradesmen. Councillor Garsden moved that the minute be referred back. The Mayor said the committee's original decision was that no tenders above £900 should be considered. The one in question, he believed, was £908 and there was so strong an opinion that local tradesmen should be allowed to compete that this tender was included. Councillor Garsden's motion was lost, and the minutes were agreed to.

Chelsea.—The annual report of the surveyor to the Vestry, Mr. T. W. E. Higgens, contains the following: The number of houses in Chelsea lighted by electricity for the last three years was as follows:

	1892-3.	1893-4.	1894-5.
Chelsea Electricity Supply Company ...	390	500	598
London Electric Supply Corporation ...	—	6	9 (?)

Extension of Mains: The Chelsea Electricity Supply Company have made various applications to extend their mains throughout the area east of Beaufort-street, and they are making steady progress with the lighting of the better-class property in Chelsea. The London Electric Supply Corporation made an application to extend their mains through Cadogan-gardens, Draycott-place, Smith-street, Tedworth-square, Cheyne-walk, and the Embankment, and I recommended the Vestry to ask the Board of Trade to compel the company to establish converting stations if they carried out any large extensions, so as not to supply at high pressure. *Street lighting*: In January the Chelsea Electricity Company made an offer to light certain streets by means of arc lights, but the Vestry were unable to accept the offer. *Pressure Records*: I have examined the pressure records of the Chelsea Electricity Company from time to time, and find that they still maintain a very good average. A voltmeter connected to their mains has been fixed in my office, and it usually stands quite steady, slightly above 100 volts. When the London Electric Supply Corporation made application to extend their mains I reported to the Vestry that the record kept at Adelphi-terrace was useless as a record of pressure in the Chelsea circuit. This led to some correspondence with the Board of Trade and the company, but the only result was to strengthen my conviction, and consequently I have not examined the company's pressure records since the matter was reported to the Board of Trade. *Meter Testing:* Only one application was made during the year to have a meter tested, which was from 46, Elm-park-gardens. Mr. Morgan Williams, A.M.I.C.E., tested it on behalf of the Vestry, and it was found to be registering 1·3 per cent. under at full load, to be correct at half load, and 15 per cent. over at a light load. As the load was very light at these premises a smaller meter was inserted by the company, and the cost of the test was paid by them. *Town Hall Lighting:* Messrs. B. Verity and Son wired and fitted up the Town Hall for electric lighting. Up to the present time the difference in cost as compared with gas is inappreciable.

Canterbury.—The Electric Lighting and Street Lighting Committees of the Town Council have reported: "The surveyor, as instructed by the Electric Light Committee at a former meeting, reported as to the information he had obtained from numerous towns and districts with reference to the electric lighting in use at such places, and after careful consideration the committee are of opinion that the time has arrived for the introduction of the electric light to the city, but that before any scheme is adopted, or works undertaken, recommend that the services of Mr. Robert Hammond, M I E E, London, be retained for the purpose of advising the Council and preparing an exhaustive report upon the whole subject, at a fee not exceeding 50 guineas, to merge in the usual engineering commission in the event of a scheme being adopted and works carried out." The Mayor proposed, and Councillor Lukey seconded the confirmation of the minutes. Councillor Harris thought the matter needed further consideration. The Brush Company evidently thought the undertaking would be a failure as an enterprise, otherwise why had they withdrawn from the proposal? When Mr Garcke went into the matter, in the time of the late Mr. Prentice, the city was being lighted with gas for £1,600 or £1,700 a year. But the figures of the Brush Company brought the estimated cost up to £2,700 and then it was found that the city could not be wholly lighted with electricity. The company would not take over the order unless the Corporation guaranteed so many lights or so much money per year. The Council had never yet received a fair and honest report as to why the Brush Company dropped the matter. Alderman Mason said it was no fault of the Corporation that they did not succeed in making terms with the Brush Company. They imposed conditions it was almost impossible to accept, and the Council were only too glad to get rid of the company, who would have tied them for 21 or 42 years. The committee might now be able to light the city at a profit—he was told that if a sufficient number of private consumers could be found they might have the public lighting at a nominal figure. They would, however, always have to depend upon gas for the lighting of some portions of the city. The committee now simply asked the Council to confirm their proposition that Mr. Hammond be asked to prepare a report on the matter. If the Council then wished to have none of it they could vote against adopting his plans. He thought this £50 would be well spent in obtaining the advice. An amendment in favour of the report being referred back for further consideration was lost, and the report adopted by five votes to one.

Glasgow. — The Special Committee on Telephone Service reported, at the meeting of the Town Council, that they had resolved to renew to the present Postmaster-General the application which the Corporation made in August, 1893, to his predecessor in office for a license empowering them to establish a telephone exchange service within the city The committee also resolve to intimate to the London County Council the making of this renewed application, and to thank that Council for the assistance they had already given to the Corporation in connection with the last application. Bailie Alexander explained that a fresh application had been rendered necessary by the change of Government. The minute was confirmed. The minutes of the Tramways Committee stated that it had been remitted to a sub committee to further consider the question of mechanical motors, and to report. Treasurer Gray objected to the appointment of this committee. It was just two years ago since the Council were assured by Mr. Paton that the committee had gone into the whole question of mechanical motors, and had found that they must revert to horse haulage They found that the overhead electric system cost £10 000 per mile double track, that the cable system cost £20 000, and they recommended that these systems should not be adopted. They had deliberately spent £400,000 on the horse-haulage system, and within a little more than a year, before a single penny had been returned to the committee, it was proposed to consider a new system. He held that there should be no foreshadowing of additional expense until the present system had been tried for another year or two. He wished his dissent entered against this proposal. Mr. J. W. Dick was surprised at the proposal now made The question of mechanical motors was considered for three years, and as a result the Council had at the time been brought face to face with the fact that nothing but horse haulage could be adopted. Their various establishments

Digitized by Google

had been constructed with a view to horse haulage. Before he could agree to the proposal it would require to be shown to him that something new had been learned with regard to mechanical motors. He moved that the minute be not approved. Treasurer Gray seconded. Mr. Walter Paton said that Treasurer Gray had completely misrepresented what he said regarding horse haulage at the outset of the tramway undertaking. What he said was that from the very nature of the case the Corporation were bound to commence with horse haulage. They had had a year's experience of it and had learned a good deal during that time. It was his opinion, and also the opinion of a good many members of the committee, that the time had now come when the question of mechanical motors should be fairly considered as applicable to some sections of the line. The minutes were approved by a large majority.

Bangor (Wales).—A special meeting of the Bangor City Council has been held to receive and discuss the following report of the Electric Lighting Committee: "The committee reconsidered Mr. Medhurst's report and the resolution of the committee of July 24, and after a long discussion it was proposed by Mr. Richard Davies, seconded by Mr. T. G. Williams, and resolved *nem. con.* that this committee adhere to the resolution passed on July 24 namely, 'that this committee having carefully considered the question of lighting the borough with the electric light, and called to their aid Mr. Medhurst, recommend the Council to apply for a license with the least possible delay, and that the committee be empowered to take whatever steps may be necessary to carry out the scheme as suggested by Mr. Medhurst in his report.'" With regard to the question of a site for the proposed electric light works, the committee reported that "Colonel the Hon. W. E Sackville West wrote stating that Lord Penrhyn was willing to sell the freehold of the field near the police station for the sum of £400, the consent of the Bishop to be obtained before any buildings were erected on the land. It was proposed by Mr. Robert Hughes, seconded by Mr. Robert Owen, and resolved, that the Council be recommended to accept Lord Penrhyn's offer, providing the Council adopt the resolution to apply for a license under the Electric Lighting Acts." Dr. Grey Edwards, in the absence of Mr. T. C. Lewis, the chairman of the committee, moved the adoption of the report. Supposing, he said, that they put down an installation as suggested, costing £13,000 to provide for 4,000 lights, the profit would be something like £100 or £150. If they increased the number of lights to 6,000, they would only have to increase their capital by £3 000. Charged at the rate of 10s. per light, these extra lights ought to bring them in £1,000 a year, so that, if they increased the number of lights, the profit to the town would be enormous, and would very much aid the Council in reducing the rates. He did not think 6,000 lights would be too many for Bangor. The 4,000 lights would be equivalent to 10,000,000 cubic feet of gas. Very large buildings were about to be erected in Bangor—the new Friars School, the intermediate school for girls, the new college hall for women students, all of which would probably take the electric light. Mr. Medhurst said that if the Council obtained a provisional order and did not take it up at once it would be rescinded, and any applying company could obtain what they asked for. He explained the way in which the electric light was being worked in several large towns Referring to an opinion expressed by Mr. Newbigging, he said that the latter, at a meeting of the Institute of Gas Engineers held at Edinburgh, stated that the gas industry had nothing whatever to fear from the electric light industry, and that the tendency was to increase the consumption of gas where electric plant had been laid down In no instance to-day was there a local authority that had supplied its own electric light which had not made a net profit in the third year of working at the latest. To-day, it was very difficult for a company to obtain the necessary legal rights, because local authorities saw that the electric light industry was profitable and they would therefore not allow any company to form a monopoly of it, as unfortunately they had in many cases done with gas and water. A canvass was usually made in towns taking up the electric light to ascertain how it would be received by the inhabitants, but that would be after the decision had been arrived at to adopt the scheme. The committee's report, with their resolution, as amended by Dr. Grey Edwards, was then carried.

Kingston-on-Thames.—The Lighting Committee of the Corporation have just issued a circular calling attention to the fact that on and after January 1 next they will make a reduction in the price of the electric light in the form of a rebate to those consumers whose use of the light exceeds two hours per day on the average throughout the year. The committee state: "The new tariff will be as follows: The present price of 6d. per Board of Trade unit will be charged until the customer has consumed sufficient electricity to average a daily use for two hours of the number of lamps he has had burning simultaneously, and all electricity consumed after that time will be charged at one-third less—viz, 4d. per unit. In carrying out this system of reductions the committee will not require the consumer to use sufficient electricity to equal two hours' daily use of every lamp fitted, the two-hour rate (6d. per unit) being charged only on the number of lamps used simultaneously, consequently those customers who have many lamps in different parts of a building and used at different times will largely benefit. An instrument will be fixed on the consumer's premises that will correctly indicate the proportion of the electricity to be charged at 6d. and 4d. per unit respectively. You will notice that this scheme benefits the small consumer equally with the large consumer. The greatest benefits are obtained under this sliding scale by regular and lengthy use of the light; therefore, those consumers who instal lamps in such places as sitting-rooms, kitchens, basements, etc., will experience the largest reductions, and when the light is used the length of time customary in such places, electricity will be found to be not only the healthiest, cleanest, and safest, but also the cheapest illuminant. As the reduction is based on the lengthened use of the number of lamps each consumer burns simultaneously, and not on the total number he has installed, it is to his own interest to instal lamps wherever he requires light, as by this means he can prolong such use of the light. The committee are making this very liberal reduction in order to encourage their consumers to use electricity more generally both for lighting, cooking, heating, and motor purposes, and to induce shopkeepers to instal the light in the residential part of their premises, and private consumers to instal lights throughout their houses instead of in one or two rooms only. The consumers' gain under the new tariff will be shown at a glance from the following accounts: old tariff for one year, 365 units at 6d., £9. 2s. 6d ; new tariff 182½ units at 6d., £4. 11s 3d.; 182½ units at 4d., £3 0s 10d ; for one year, 365 units, £7. 12s. 1d ; thus saving £1. 10s. 5d. per annum. Consumers with larger installations using their lamps in a similar manner will of course obtain the benefit of a like proportionate reduction. Under the new tariff hotels, public-houses, and all buildings where artificial light is used for a lengthy period will benefit largely. Consumers deciding to adopt the demand indicator system of rebate will of course accept it in substitution for any other mode of discount or reduction otherwise allowed. The Lighting Committee would take this opportunity of again pointing out to the householders in the borough that they are all directly interested in the success of the electric lighting undertaking of the Corporation, and that benefit to the ratepayers from the successful financial working of the central station can only be brought about by a considerable increase in the demand for electricity, and the committee feel sure that if in his own interest every ratepayer will well consider this question he will see the advisability of becoming a consumer of electricity supplied from the works, in which as a ratepayer he is a shareholder. There is no doubt that electricity as an artificial light is unrivalled, whether installed in private or business premises. Upon application a demand indicator will be fixed on the consumer's premises at the Corporation's expense, for which a rental of 1s. per quarter will be charged."

Lambeth.—The Lambeth Vestry have considered another phase of the electric lighting question. Some time since the Brush Electric Lighting Company wrote offering to take over from the Vestry the electric lighting order, and had since given notice of their intention to apply in December next for the transference of the order from the Vestry to themselves. A similar intimation had been received from the Capital and Counties Electricity Company. The Lighting Committee (supplemented by the addition of two representatives from each of the standing committees) now report having considered these communications, and resolved to recommend the Vestry to write to the two companies "intimating that the Vestry have no intention of proceeding at present under the provisional order granted to them" Mr. Nash, at the last meeting, moved the adoption of the report. Mr. Everett moved, as an amendment, "that all words after 'vestry' in the recommendation be deleted, and the following substituted: 'while not in possession of sufficient information to justify an immediate proceeding under the provisional order obtained, has no intention of surrendering the order.'" Mr. Everett remarked that although he was not in favour of immediately going on with the electric lighting scheme, yet he could not agree with the proposal that they should virtually surrender the order. He apprehended that the Vestry would agree with him in saying that if they adopted the recommendation the companies would take their decision to the Board of Trade, and probably that Board, acting upon its tenour, would revoke the order. At the same time he was bound to say that since the question was previously discussed many of them had carefully been on the look-out for information as to the experience of other parishes Whitechapel, he understood, was in a similar predicament to Lambeth, and the Vestry of that parish had passed a resolution in similar terms to that which he now proposed. He pointed out that there could be no harm in waiting for a short time. They had, for instance, recently been informed that the London County Council lent money for electric lighting purposes at 2¾ per cent., as against 3½ per cent. previously. That in itself would mean a great difference in the ultimate cost; indeed, in St Pancras the margin between the higher and lower rate of interest would almost cover the cost of generating for one year. Looking at the more recently available information, he thought the Vestry would be unwise in allowing a private company to come in and make a monopoly of the electric light. He regarded it as the Vestry's duty to keep the companies out of the parish; and even if the Vestry waited before they took the scheme in hand, they would gain through the daily diminution in the price of electrical apparatus. Mr W. J Hosking seconded, pointing out that the whole point now before them was whether they would unconditionally surrender the order or seek further time to consider the question. Many things had, as Mr Everett said, changed in connection with electric lighting—the interest on loans had become lower, and the price of electrical apparatus was daily decreasing. At the same time, while he agreed that there should be delay for the present, he could not consent to the arguments of some that they should wait until the electric lighting system had become perfect. It was through taking up that position that their forefathers gave the gas monopoly to private companies; and had the pioneers of railways been influenced by similar considerations, they would never have advanced beyond the primitive locomotive of George Stephenson. Alder-

Digitized by Google

man Hubbard said that the opponents of the scheme had industriously assured the parish that Mr. Preece's scheme proposed an outlay of £300,000, and compared the expenditure to throwing that amount of money in the street As a fact, Mr. Preece recommended the spending of £75,000 as an initial outlay, and this would take four years to spend; so that if the scheme proved abortive, £75,000 would be the amount lost, and not £300,000, as had been represented. Moreover, he (Mr. Hubbard) had very good evidence that Mr. Preece was too liberal in his estimate—that £40,000 would be nearer the initial outlay and that that amount would provide a valuable asset for Lambeth. He quoted the experience of Leeds and Liverpool to show that when a company had been once let in the municipal authority could not acquire the monopoly except on payment of a large premium. St. Pancras, too, furnished them with a capital object-lesson. Mr. Bennetts said there could be no doubt that the municipalisation of electricity was proving a success. The parish of Islington was about to commence operations, Shoreditch was opening out its works, and the little parish of Ealing was also about to start the electric light. He suggested that the committee should be appointed to investigate the whole matter, in order that when December came they might have something definite to lay before the Board of Trade. Mr. Ogilvie warned the committee that they were placing too much reliance upon the report of Mr. Preece, who was the alpha and omega of their scheme He looked upon the report of Mr. Preece as distinctly the report of an enthusiast. He (Mr. Ogilvie) would like to see the electric light available to Lambeth, but he certainly did not think himself justified in giving the parish a luxury out of the rates. He thought they should have a special night for the discussion of the subject On a show of hands the amendment was adopted without dissent, and the report as amended was adopted.

PROVISIONAL PATENTS, 1895

SEPTEMBER 2.

16427. **Improvements in electric bell pushes.** Eduoard Percy Cranwill Girouard, 47, Lincoln's-inn-fields, London.

SEPTEMBER 3.

16439. **Improvement in dynamo-electric machines.** Frederick Henry Royce, Eastbourne, Holland-road, Chorlton-cum-Hardy. (Complete specification.)

16450. **Improvements in stage or like arc lamps for alternating currents.** Alfred Sykes, Market-place, Huddersfield.

16482. **Improvements in electric and pneumatic bell pushes.** Harry George Warner, 23 Coleman-street, London.

16494 **Improvements in or relating to supports for overhead electric conductors.** William Robert Lake, 45, Southampton buildings, Chancery lane, London. (Charles Jordan Goodwin, United States.)

16521. **Improvements in and connected with the overhead system of electric traction.** Walter Charles Bersey, 53, Chancery-lane, London.

SEPTEMBER 4.

16557. **Electro-deposition of gold and silver.** Emile Andreoli, 18, Somerleyton-road, Brixton, London. (Complete specification)

16562. **Improvements in multiple electrical switches.** Hugo Hirst, 73, Stephen's-road, Upton Park, London.

16569. **Improvements in the manufacture of electrodes for voltaic batteries.** Ludwig Epstein, 28, Southampton-buildings, Chancery-lane, London

16582. **Improvements in storage battery plate.** Fred Newell Tilton, 40, Chancery-lane, London

SEPTEMBER 5.

16635. **Improvements in the regulation and construction of electric motors.** William Law Pakenham and John Charles Howell, 55, Chancery-lane, London.

16651. **Improvements in electric glow lamps.** Ernst Rosenberg, of the firm of H. M. Salmony and Co., 45, Southampton-buildings, Chancery-lane, London. (The firm of Von Severen and Schwabe, Germany.)

16659. **Improvements in and relating to electric railways.** Reginald Belfield, 31, High Holborn London. (The Foreign Electric Traction Company, ——.)

SEPTEMBER 6.

11728A. **An improvement in voltaic batteries** William Shaw, 70, Wellington-street, Glasgow. (Date claimed under Patents Rule 19, June 17, 1895) (Complete specification.)

16700 **Apparatus for supplying electrical energy to tramcars from underground conductors.** Siemens Bros. and Co., Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany)

16701. **Contact apparatus and appliances in connection therewith for facilitating the passing of tramcars over crossings and switches in electrical tramways with underground conductors.** Siemens Bros. and Co, Limited, 28, Southampton-buildings, Chancery-lane, London. (Messrs. Siemens and Halske, Germany.)

16702. **An element for secondary voltaic batteries.** Prosper Vandersmissen, 28, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16736. **Improvements in or connected with apparatus for extracting gold and silver from cyanide solutions by electricity.** Johannes Pfleger, 47, Lincoln's-inn-fields, London.

16737. **Improvements in or connected with electrical apparatus for extracting gold and silver from cyanide solutions.** Johannes Pfleger, 47, Lincoln's-inn-fields, London.

SEPTEMBER 7.

16742. **Reversible rotary incandescent electric light switch.** John William Fielding, 59, Dairyhouse-road, Derby.

16794. **Improvements in and relating to the calibration of electric measuring instruments.** Sydney Evershed, 1, Queen Victoria-street, London.

16796 **Improvements in electromagnets.** Illius Augustus Timmis, 2, Great George-street, Westminster.

SPECIFICATIONS PUBLISHED.

1894.

15575. **Gasoliers, electroliers, etc.** Smith.

15774. **Electric cables.** Saunders. (Greey and another.)

16105. **Electrical deposition of zinc, etc.** Heathfield and Rawson.

17529 **Telephone receivers, transmitters, etc.** Higgins.

18274 **Arc lamps** Brockie.

18274A **Arc lamps.** Brockie.

19444. **Arc lamps.** Stout.

19807 **Electric door contact.** Oppenheimer.

20043 **Arc lamps.** Geipel.

22043. **Electrically heating metals.** Holland.

1895.

4939. **Electrolysis.** Andreoli. (Second edition.)

13388 **Arc lamps.** Devonshire (Thomson and another.)

13389. **Regulating speed of continuous-current motors.** Devonshire. (Wightman.)

13404. **Dynamo-electric machinery.** Royce and Claremont.

13550. **Dynamo-electric machinery.** Royce and Claremont

13564. **Electric regulators.** Bonsor.

13638. **Incandescent lamp mantles.** Crocker.

NOTES.

Books Received.—From the office of the New York *Electrical Engineer* we have received "Electrical Engineering Leaflets," by Prof. E. J. Houston, Ph.D., and Prof. A. E. Kennedy, F.R.A.S., vol. 1 being devoted to the elementary grade, vol. 2 to the intermediate, and vol. 3 to the advanced grade.

The Electric Light in Russia.—The use of the electric light is gradually extending in Russia. Experiments with the illuminant in the town theatre and in various business establishments in Riga having given satisfaction, it is proposed to light the public buildings and streets of that city by electricity.

The Canadian Electrical Association.—The annual meeting of the Canadian Electrical Association was held at Ottawa on September 17, 18, and 19. It was expected that the attendance would exceed that of the successful meeting at Montreal last year, and the papers to be read promised to be of fair interest.

Telegraph Charges to India and the East.—We learn that the London Chamber of Commerce is in correspondence with similar corporations throughout the kingdom, inviting their co-operation with a view to securing a substantial reduction in the rates at present charged for telegrams to India and the East.

Electricity in Egypt.—A considerable addition is shortly to be made to the plant at the central electric stations in Cairo and Alexandria. Two Brown and Boveri dynamos, driven by a pair of 200-h.p. steam-engines by Sülzer and Winterthur, are to be put down at Cairo, and a 100-h.p. engine and dynamo at Alexandria.

Aluminium Conductors.—M. E. C. Grammont has erected an overhead line made of aluminium for the transmission of electric energy between his two factories at La Plaine and Pont de Chérin, in the Isère Department. In order to avoid joints, M. Grammont has satisfactorily soldered the wires end to end with a blowpipe.

Helmholtz Memorial.—German papers announce that a memorial tablet in honour of Prof. Helmholtz has been affixed to the house, No. 8, Haditzstrasse, at Potsdam, where he was born in 1821. We also hear of an intention to erect a joint monument in memory of Werner Siemens and Helmholtz in front of the Technische Hochschule at Charlottenburg.

Military Telegraph Lines on the St. Gotthard.—It is announced that the military department of the Swiss Bundesrath has requested a credit of 56,000f. for the purpose of establishing telegraphic connections on the St. Gotthard. It is proposed to erect wires between Andermatt and Dissentis and Dissentis and Olivone, and to join up the military lines on St. Gotthard to the Gletsch Station in the Upper Rhone valley.

Electric Safety Lamps.—As the result of experiments the Berlin fire brigade have decided to adopt the Fiehn and Sehrndt accumulator lamp. It is designed to light rooms in which explosive materials are stored, or which are filled with easily-explosible gases. It burns for about 10 hours and weighs 5½lb. The lamp, it is stated, has already been adopted by the fire brigades of Frankfort on-Main, Bremen, Stettin, Chemnitz, Halle-a-S., Elbing, and by Krupp, of Essen.

Electric Railways in the United States.—It is computed that there are at the present time 850 electric railways in the United States, with more than 9,000 miles of track, with 2,300 cars, and representing a capital investment of 400,000,000dol. An idea of the rapidity and magnitude of the extension of this system of traction may be formed when the fact is noted that in 1887 the electric roads in the United States numbered only 13, with about 100 cars in operation.

Electric Lighting in India.—Applications have already been submitted to the Government of Bengal for permission under the Electric Lighting Act to lay mains in the streets of Calcutta for the benefit of the general public. The question of lighting the streets by electricity is, owing to the gas company's contract with the Corporation, one for the future, a correspondent writes; but he expects to find the Eden Gardens and the Calcutta maidan ere long lighted by the new illuminant, in addition to the jetties and several public offices.

Electric Tramways in Warsaw.—A request for a concession for building and working an electric tramway system in the Polish capital has been laid before the president of the city, General Bibikoff, by a syndicate at the head of which are Major-General von Guilbert, of Warsaw, and Dr. Zelime, of Leipzig. The Allgemeine Elektrizitäts-Gesellschaft is interested in the project. The capital of three million roubles will be furnished by the Commercial Bank of Warsaw. The scheme has yet to be submitted to Governor-General Shouvaloff.

Resuscitated.—A lineman, who has been for 14 years in the employ of the Rochester Gas and Electric Company, recently received a shock from a "live" wire at Rochester N.Y., and lay apparently dead for six minutes. He recovered consciousness after being subjected to the d'Arsonval treatment. His right hand and wrist were badly burned, but he was otherwise uninjured. The wire that he came in contact with carried 1,600 volts, and he seemingly received the full voltage by short-circuiting the line with his body.

The Berlin Electric Tramways.—As we announced last week, the first electric tramway, built by Messrs. Siemens and Halske, was opened in Berlin on September 10. The line runs from Badstrasse, Berlin, N., to Pankow. The gauge is 1·435 metre. The current is supplied through overhead wires from the central station in Pankow. Ornamental Mannesmann steel-tube standards are used. The rails are utilised for the return current. The motor cars have 18 sitting and 12 standing places. The motor is under the car floor. The cars run at a speed of from 10 to 12 miles an hour, and the fare for the whole distance of about two miles is only 10 pfennige—say, 1½d.

The Pacific Cable.—With reference to the note under this head in our last issue (p. 284), it is now stated that the negotiations for the contract with the Hawaiian Republic were conducted with the greatest secrecy, and when it became known that it was signed a meeting of the Honolulu Chamber of Commerce was immediately called, at which the British and German members protested against the granting of any exclusive right, as it would preclude the construction of an English, German, or French Pacific cable for the next 20 years, since the Hawaiian group are the only islands in the North Pacific which afford a landing-place for so long a cable.

An Important Financial Operation in Copper has, it is stated, just been concluded. It is announced that Messrs. Rothschild have obtained a very large interest in the shares of the well-known Anaconda Mine of the United States. The capital of this company is about six millions sterling, and the shares of 25dol. each are expected to be

Digitized by Google

shortly offered in the London market at a substantial premium. The figure spoken of is £7, which would make the capitalisation of the company nearly £8,500,000. Large profits have been made by this mine in the past, and the acquisition by English capitalists of a large interest in the company will exercise considerable influence on the position of the copper market.

Marking Incandescent Lamps.—The *Sprechsaal* speaks of the advantage of numbering each lamp as it leaves the works; but the plan of ticketing them with an adhesive label takes too much time, and there is the risk of the ticket coming off. It therefore recommends writing directly on the glass, and gives the following formula: Dissolve 36 grammes of sodium fluoride and seven grammes of potassium sulphate in 500 grammes of water. In another vessel 14 grammes of zinc chloride are dissolved in 500 grammes of water and 65 grammes of hydrochloric acid are added to the solution. Immediately before writing the inscription, equal parts of the two solutions are mixed and applied to the glass either with a pen or a pencil. An indelible inscription is said to be the speedy result.

What it is.—Electricity "is as old as life, as mysterious as death, and as everlasting as eternity. It is as bright as the stars of heaven, it is as silent as the graves of men. It is as powerful as fate, as subtle as sympathy, as swift as thought. And it is developing as rapidly as Jack's fabulous beanstalk." At least, so thinks a well-known Detroit journal; and the biting gnats in Jersey City must also be of this opinion if we attach any importance to the somewhat sarcastic remarks of a New Yorker visiting that place. "What a stranger might take for fenders on the trolley cars are not," he says, "fenders at all, but mosquito catchers. When the mosquito is struck the catcher, with a sudden twist, tosses its body from the track. More mosquitoes than citizens are killed yearly by the trolleys."

Electrotherapy.—The American Electro-Therapeutic Association has just held its fifth annual meeting at the College of Physicians and Surgeons of Ontario, in Toronto. Herr von Bergmann, who attributes much of the progress in cerebral surgery to improvements in technique and instruments, employs a circular saw operated by electricity for dividing the outer table of the skull. Through the energy and activity of Dr. Georges Apostoli, president of the French Society of Electrotherapy, the society now has an official organ, *Le Bulletin Officiel de la Société Française d'Electrothérapie.* The latest electrical instrument is the autoscope, devised by Dr. Kerstein, of Berlin, for examination of the larynx and trachea. It consists of a thick tube, 20cm. long, ending in a gutter-like point; the tube being tightly screwed to a Gaspero electroscope at a right angle. It is stated that when this instrument is correctly introduced the patient readily breathes through it, a complete view of the larynx and trachea being thus obtained.

A New Electric Alarm.—The *Revue de l'Electricité* describes an alarm apparatus, the joint production of a French engineer, M. Laville, and M. Plisenier, a Belgian. The "Vigilant," as it is called, has recently been tried at the Brussels Northern Railway Station, and is designed to take the place of the ordinary electric bells and to be attached to safes, doors, windows, etc. The least disturbance of the object to which it is fixed causes a loud-sounding bell to ring. When used as a fire-alarm the apparatus is furnished with a multiple-combination letter-lock, which can only be opened by someone in possession of the key word. There are no springs or electromagnets in the apparatus, and the inventors claim that it cannot get out of order. The Belgian State telegraphic engineers have, it is stated, experimented with and expressed their approval of the apparatus.

Measurement of the Specific Inductive Capacities of Water, Alcohol, etc.—In *Phil. Mag.* Mr. Reginald A. Fessenden says that it has hitherto been accepted that the high values for the specific inductive capacities for water, alcohol, and some other similar liquids which have been obtained by various experimenters are correct. If this were so, Maxwell's rule for the relation between specific inductive capacity and the index of refraction would not hold in these cases, and the phenomena of dispersion, etc., have been called in to explain this anomaly. The author finds, however, from the results of experiments described in the paper, that these high values are not correct, but that the true values are in every one of these substances very nearly equal to those called for by the theory. The cause of the errors lies in the fact that electrolysis gives a capacity effect. It is for this reason that Kohlrausch's method almost always gives erroneous results, as what is measured is not the resistance of the electrolyte, but its impedance.

The Telephone Service.—A correspondent writes: "The Duke of Norfolk has initiated a series of investigations with reference to the telephone. The men whom he has entrusted with the mission of enquiry have, too, a personal significance, which is not calculated to lessen the importance which is being attached to the incident. They are Mr. Preece, the chief electrician of the General Post Office, and Mr. H. C. Fischer, controller of the Central Telegraph Office, both of whom are known to entertain strong opinions as to the assumption by the State of the telephone interest. They are at present in Germany studying the system in operation in that country." By the way, the *Elektrotechnische Zeitschrift* of Sept. 12, remarks, in noting the above fact, that Mr. Fischer is a born German, and that he at one time belonged to the Hanoverian Telegraph Direction. He left Germany when he was fifty and came to England to extend his knowledge, got into the Telegraph Department, and gradually worked his way up the ladder of promotion.

Gases of the Helium and Argon Type.—Herr Bohuslav Brauner has treated cerite with sulphuric acid and then with water. A gas is produced showing the negative behaviour of nitrogen, but mixed with some hydrogen; the same mineral when heated in a vacuum alone, or with a sulphate, yields gases belonging to the helium and argon type; this was also noticed with several other Bohemian uranium ores. Pitchblende, from Pribram, shows a peculiar behaviour; with a feeble current, in a Geissler tube, with aluminium electrodes, it emits a blue-violet light; with a stronger current, a crimson light. With the spectroscope, the lines, D_3 and D_2, are seen together with 19 other lines or groups of lines—three of the lines belong to hydrogen and one in the red to argon. After some time the helium lines disappear entirely, one by one, then the hydrogen lines go, and an extremely feeble, but characteristically fluted hydrocarbon spectrum makes its appearance. The absorption of helium by aluminium proves its metallic character.

A New Constant Battery.—M. Morisot, professor at the Faculté des Sciences in Bordeaux, has recently brought before the meeting of the Association Française pour l'Avancement des Sciences a new type of battery. An outer vessel contains the positive pole, a plate of retort carbon, which is immersed in the depolarising liquid, composed of one part of sulphuric acid and three parts of a saturated solution of potassium bichromate. The bichromate must be dissolved before the acid is added, and the saturation is kept up by crystals of bichromate contained in a short funnel in the upper portion of the liquid. A porous pot standing in the depolarising liquid contains a weak

Digitized by Google

solution of caustic soda (specific gravity about 1·05). The plate of amalgamated zinc which forms the negative pole is in a second porous pot inside the first, and filled with a strong solution of caustic soda (specific gravity about 1 25). The E.M.F. of the cell is 2·5 volts at the outset, and remains above 2·4 volts for at least 10 hours. The interior resistance is about 0·8 ohm, but it varies according to the thickness and quality of the porous pots. M. Morisot attributes the increase of 0·4 volt of E.M.F., compared with the ordinary bichromate cell, to the substitution of the alkaline solution for the ordinary acid.

Electrical Coal-Cutting.—A number of gentlemen connected with the coal industry were recently invited to East Plean Colliery, Stirlingshire, to witness the working of a coal-cutter patented by Mr. Hurd. The principle of the machine is a bar-cutter worked electrically from a motor cased within the apparatus, and the advantages claimed are: The bar cuts independently of position, either under or, as in the East Plean Colliery, between seams of two qualities of coal; there is almost absolute steadiness, a great feature in any electrically-driven machine; the electric motor and gearing, the parts being few and simple, are built into the machine, which, being cased over, forms a substantial tool which would not suffer much from falling roof or other such accident; an ingenious principle is introduced of entering the cutter-bar from the reverse side of the machine, to which a self-cleaner may be applied; it then makes its own holing, and can, when required, shear the coal vertically; this bar can be separately adjusted while the machine is in motion to meet any irregularities of the road, and keep the holing continuously in the best position. The machine was worked downhill on an incline varying from 1 in 5 to 1 in 10, cutting, it is stated, 3ft. 6in. deep at the rate of about one yard in two minutes.

The Condensation of Fumes by Static Electricity.—In the current number of the Columbia School of Mines *Quarterly*, Mr. Melvern W. Iles, superintendent of the Globe Smelter, Denver, Col., calls attention to the desirability of some cheap method for the generation of static electricity to condense the fumes from volatile metals. The writer thinks that the subject of the volatility of gold, silver, and lead has not received sufficient attention, many substances, like copper, which is classed by the practical metallurgists as being non-volatile, being found to suffer at least 6 per cent. loss in fumes. He believes that the invention of a cheap method for the generation of static electricity will enable metallurgists to save a very large amount annually in the reduction of all the well-known volatile metals, and considers the matter one which will repay the attention of electricians. The article refers to the well-known experiments of Lodge in clearing an atmosphere clouded with dust and smoke, and calls attention to a United States patent granted to Alfred O. Walker, dated May 25, 1886 (No. 342,548), on a "Process of Depositing Solid Particles Suspended in the Air or Gas," and also to an article by E. Dieudonné, printed in *La Lumière Electrique* in the spring of 1886, on "The Condensation of Fumes by Static Electricity."

The Electro-Harmonic Society.—A smoking concert will be held on Saturday, September 28, at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., commencing at eight o'clock. The following is the programme—Part I.: part song, (*a*) "Come Live with Me" (Maunder), humorous quartette, (*b*) "Quite Sufficient" (M.S.), the "Schartau" Part Singers; song, "The Tempest of the Heart" (Il Trovatore) (Verdi), Mr. Arthur Appleby; pianoforte solo, "Caprice sur les Airs de Ballet d'Alceste de Gluck" (Saint-Saëns), Mr. Alfred E. Izard; humorous recitation, "Astronomy Made Easy" (Anon.), Mr. W. G. Churcher; ballad, "Take a Pair of Sparkling Eyes" (Sullivan), Mr. John Bartlett; flute solo, Mr. Frederick Griffiths; humorous song, Mr. Herbert Schartau. Part II.: old melody, "Genevieve" (specially arranged), the "Schartau" Part Singers; new song, "The Gay Hussar" (Sullivan), Mr. Arthur Appleby; humorous recitation, "My Haircutter" (Turner), Mr. W. G. Churcher; song, "The Wonders of the Deep" (Jude), Mr. William Bradford; madrigal, (*a*) "It was a Lover" (Sixteenth Century), humorous quartette, (*b*) "Only Once" (M.S.), the "Schartau" Part Singers; flute solo, Mr. Frederick Griffiths; humorous song, Mr. Herbert Schartau. Messrs. T. E. Gatehouse and Alfred E. Izard will be the musical directors.

The Trolley Question.—The Chicago tramway magnate, Mr. Charles T. Yerkes, states that he has found in the overhead trolley system a very valuable auxiliary to his cable trunk lines, and his advocacy of electricity is due entirely to his belief in its dividend-earning capacity. The introduction of the trolley on the lines of the North and West Chicago street railroads, formerly operated by horses, he considers to be an important recommendation for the electric motor, and the announcement of the result of this transformation and its effect upon the receipts and expenditure of the companies are, he says, gratifying to all who are interested in this method of propulsion. Mr. Yerkes has given at an interview his reasons for advocating the trolley system, and he explains the relations of the cable companies to the auxiliary electric companies. He affirms that as soon as a line is equipped electrically the traffic increases, and that those lines now worked by electricity show an improvement of 30 per cent. The net earnings for seven months of operation by electricity manifested an increase of 24 per cent. compared with the corresponding months of last year; and while more passengers have been carried than was the case a year ago, the working expenses have been less. It is reported, by the way, that electric funeral cars are shortly to be introduced in Chicago. They are "intended to furnish a cheap means of reaching the various cemeteries with as as little discomfort as possible."

Queensland and the Pacific Cable.—The question of laying a cable across the Pacific, a Sydney paper to hand says, has been brought forward again by the announcement made by Mr. J. G. Ward that the New Zealand Government intended to introduce legislation for the purpose of co-operating with Canada in the establishment of the Pacific cable. Queensland is also in sympathetic accord with Canada on this subject, but some friction appears to exist over the matter between Queensland and New South Wales. The Postmaster-General (Mr. Cook) says some comment was made about the want of foresight shown by the Queensland Government in not joining in the guarantee to the Eastern Extension Company. The Queensland Postmaster General, in explanation of the attitude of his Government, claimed that there had been an understanding at the Hobart Postal Conference that if Queensland joined in the guarantee to the Eastern Extension Company the New South Wales Government would help Queensland in regard to the Pacific cable, and he complained of New South Wales not having adhered to this agreement. Mr. Cook denies that any such understanding was arrived at, and points out that if Queensland had joined in the guarantee with the other colonies she would have gained materially. The Queensland Government were invited to contribute a certain sum towards the Eastern Extension guarantee, but nothing towards the subsidy to which all the other colonies contribute a proportional amount. Had Queensland assented to this very favourable arrangement, the journal adds, the rates for her cable messages would have been reduced from

Digitized by Google

9s. 4d. to 4s. 9d. per word, and she would have had to pay nothing under the guarantee, for the result of the year's cable work has been so satisfactory that the guarantee to the Eastern Extension Company has been more than covered, and none of the colonies will now have to pay anything under it.

The Spectrum of Carbon from the Electric Furnace.—In a recent communication to the Académie des Sciences, M. Deslandres stated that M. Moissan recently pointed out that the carbons which he uses for his electric furnace are purified by the passage through them of the large currents employed. As it is very difficult to purify carbon by the chemical way, M. Deslandres emphasises the importance and interest of this property of the electric furnace, especially to spectroscopists, who often use pure carbon in qualitative analysis. It was on this account that M. Deslandres paid special attention to the statement of M. Moissan, and carried out an investigation to verify its correctness. M. Moissan placed at M. Deslandres' disposal two carbon electrodes, a positive and a negative, 20cm. long and 5cm. thick, which he had made use of in some electric furnace experiments. M. Deslandres took from each electrode small pieces of carbon at distances of 15cm., 10cm., 5cm., and 1cm. from the arc. He found that the pieces which were taken from the electrode at some distance from the arc showed the ordinary impurities of carbon — namely, alkaline metals, together with copper, iron, and silicium. When, however, he came to examine the pieces which had been taken close up to the arc, the bands denoting impurity finally disappeared, with the exception of the calcium bands, which, although very much reduced, always remain visible, a fact which M. Deslandres attributes to the lime wall of the furnace, which is probably partly volatilised when large currents are used. M. Deslandres attributes this purification of carbon to a purely physical cause, the impurities being much more volatile than carbon, and being therefore vaporised before it. The purest carbon was obtained from the mushrooms which form on the negative, and with one of these mushrooms M. Deslandres obtained a spectrum which contains fewer impurity bands than any of the spectra hitherto published.

The Bolton Technical School.—Technical education is making great strides in Bolton, and new premises have recently been acquired in connection with the scheme of extended scientific and practical instruction. Upon lately visiting the technical school, Prof. Beaumont, representing the City and Guilds of London Institutes, paid the institution a very high compliment by observing that in point of instruction and arrangement of work the classes were second to none in the country. In order that instruction may be organised in machine drawing, building drawing and construction, physics, applied mechanics, steam, metallurgy, and woodwork, the rooms at Mawdsley-street have been rearranged. On the top floor is a well-appointed room, 60ft. by 30ft., laid out with specially prepared tables and seats for drawing purposes, and in close proximity is an apartment of similar size fitted with benches and tables, and six electrical connections for students taking up practical physics, electric lighting, and magnetism and electricity. The hosiery-room has been converted into a handsome class-room for the advanced applied mechanics, steam, horticulture, and mining students. Alterations effected in the large lecture-hall have given increased seating capacity, and the place has been thoroughly beautified. As the gas-engines have been disposed of the building is lighted by electricity from the Corporation mains, Mr. J. H. Rider, the electrical engineer, having speedily completed the connection. The space under the gallery is converted into a dark-room for the use of photography students, and demonstrations are to be given in the various processes, fully illustrated by new apparatus. Woodworking, carpentry and joinery, cardboard work, typography, and theoretical metallurgy will be taught on the ground floor, and as the woodworking-room is near the lower lecture-hall, greater facility is secured in passing from the classroom into the workshop for practical instruction. The bench accommodation has been increased, and is now sufficient for 50 pupils. In the basement the subjects taken will be chemistry, practical metallurgy, and machine drawing, special arrangements having been made in connection with the latter class, as it is anticipated that there will, at least, be 200 pupils. Last session the accommodation for the practical metallurgy and assaying class was altogether inadequate, and double the number of furnaces have been built, testing-benches have been erected, and the room has been renovated and furnished. The higher portion of the premises facing Bridgman-place has been gutted and replaced by a spacious entrance hall and well-adapted classrooms. The basement is to become an important part of the institution, the floor having been lowered a foot and the windows improved and enlarged to secure better light. This section will be devoted to engineering, wood-turning, metal-turning, and working, moulding, and smithy work. In the south end, separated from the workshops by a glazed partition, is a large engine-house, containing one 100-h.p. high and low pressure engine, supplied by Messrs. Hick, Hargreaves, and Co. This will provide the whole motive power, as well as drive two large dynamos placed in the centre of the room, and arranged to be used for instruction in the electric-lighting classes. Mains are laid from the dynamos to the switch-board for class demonstrations, and other means are adopted for the advantage of students in this branch of scientific work. The engine-room affords accommodation for instruction in applied and theoretical mechanics, steam, magnetism, and electricity, and electric lighting. This department will be under the control of an engineer to be appointed shortly, and he will also have charge of the engineering tools and lighting. Adjoining is the boiler-house, fitted with one of Messrs. Hick, Hargreaves, and Co.'s high-pressure Lancashire boilers. The main portion of the basement constitutes the engineering workshop, which is exceedingly well equipped, and when in full swing will represent a modern works of no mean order. Three lines of shafting are fixed to brackets on the pillars, and serve for the engineering, wood and iron turning, and brass finishing. Engineers' benches for 50 students are placed immediately under the windows, good light being thus obtained. There are also two continuous beds of lathes for 20 students, a range of iron hand turning lathes, drilling and miling machines, cutter grinder, screw-cutting lathes, small finishing lathes for iron and brass turning, shaping and planing machines, grindstones, and bench and hand saws. At the entrance to the basement is the moulding and smithy department, with hearths and all accessories. The weaving-room, on the ground floor, is naturally one of the principal characteristics of the institution. Not the least interesting feature of the curriculum of the technical school is the teaching of the Russian language. Bolton does considerable trade with Russia, and it is necessary for many workmen in the engineering and cotton-spinning industries to possess a knowledge of the language of that country. Through a generous offer made by Mr. W. M. Musgrave, J.P., the committee has been enabled to arrange for a class for imparting instruction in Russian, and has secured the services of a highly qualified teacher.

A NARROW-GAUGE ELECTRIC LOCOMOTIVE.

BY R. W. WEEKES, WHIT.SCH., A.M.I.C.E.

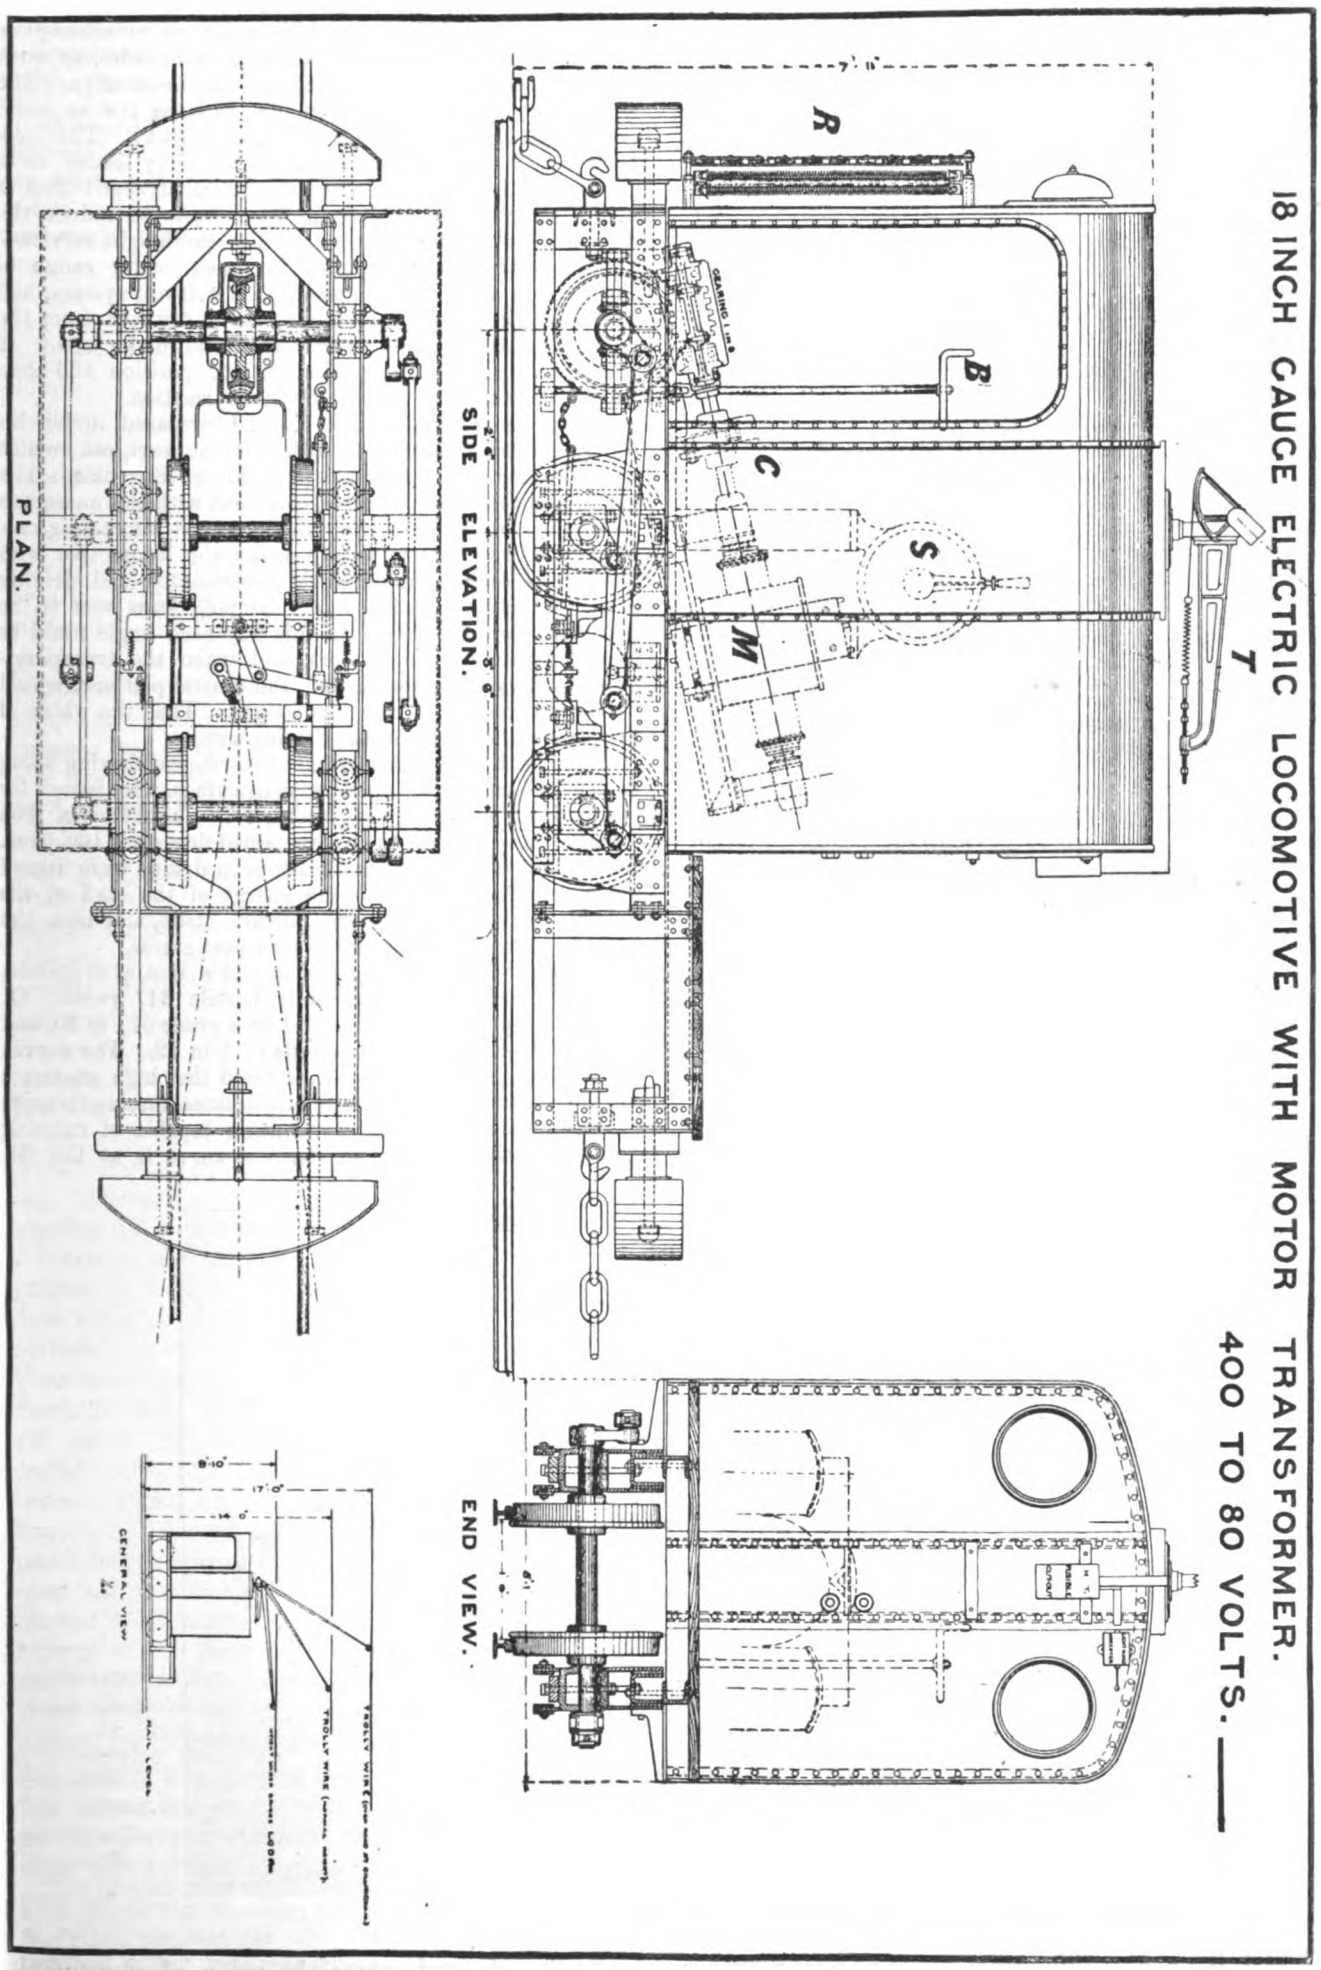

Fig. 1.—General Views of the Locomotive.

A new electric locomotive with most interesting features has recently been built by the associated firm of Messrs. Easton, Anderson, and Goolden for the 18in. line running between the electrical school at St. Mary's Barracks,

Digitized by Google

Chatham, through the dockyard, into the submarine mining establishment at Gillingham. This locomotive is the result

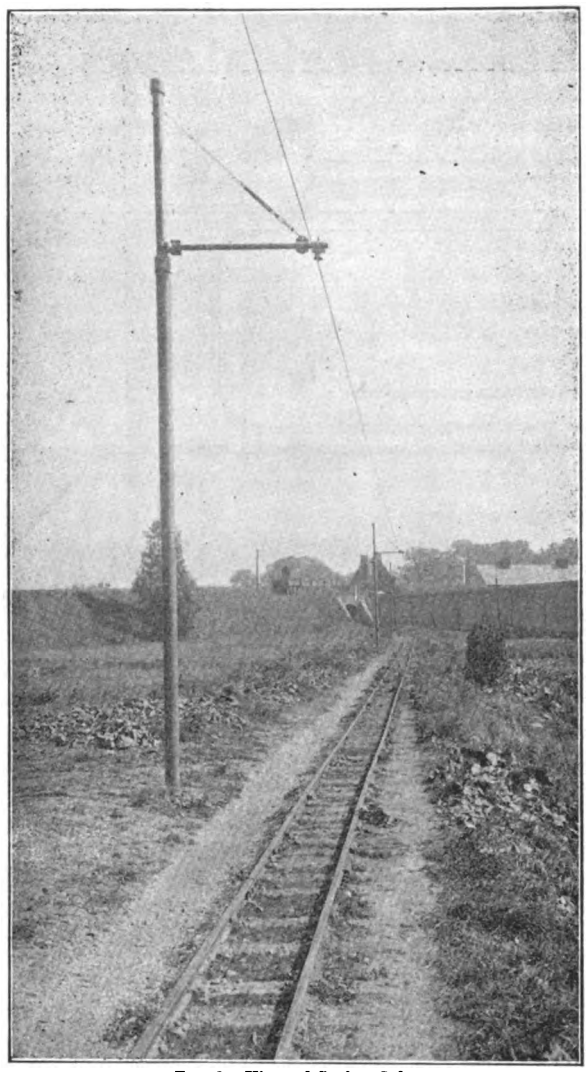

FIG. 2.—View of Spring Pole.

of the accumulative ideas of many workers. Major A. Bagnolds, R.E., first talked the matter over with Mr. Gisbert Kapp when the latter delivered his course of lectures on "Alternating Currents" at Chatham in 1891. The matter assumed a more definite form at the end of 1892, when the following leading essentials of design were fixed:

The locomotive was to be used on a siege railway of 18in. gauge, and hence was to work as noiselessly as possible. To assure the mounting of stiff grades, as much load as possible to be carried on the locomotive. The centre of gravity of the locomotive to be as low as could be arranged, and the wheel base to be small. The locomotive to be capable of starting when fully loaded on a grade of 1 in 22. The motor to be so arranged that it could act as a constant-current transformer to reduce the 400 volts of supply to 80 volts for search-light service—the idea of this being that a much wider range of fortifications could be connected to a 400-volt system, and that when projectors were wanted at a distance from the generating station, the locomotive would, under cover of the night, transport the projectors into position and then supply the necessary current by transformation.

As private assistant to Mr. Kapp, I prepared, under his direction, a series of designs with different gears, etc., which we submitted from time to time to Major Bagnolds. The confined space at our disposal, combined with the numerous requirements, rendered the subject a most interesting one. Finally, it was determined to make the locomotive with two bogies, each complete with electromotor and driving gear. A central platform for carrying guns was to be placed across these two. In this way each bogie could be used separately for light work, and when the transportation of heavy guns was needed, the central platform would be laid on the two to bear the weight. Then the whole of the load would come on the driving axles.

These details and the method of worm-gear driving being determined on, specifications, with drawings, were issued for one section of this composite locomotive—*i.e.*, one bogie. The order was placed with the above-named firm early last year. At the first trials some modifications in details were found necessary, but, thanks to the energy of the staff of the electrical school, these were quickly made, and now the locomotive is regularly used to transport stores.

The Line.—The total length of this 18in. line, as at present equipped for electric traction, is 1 mile 347 yards. Of this length quite a quarter is laid on a grade of 1 in 30, and another longer section has a grade of 1 in 22. The curves also are sharp, but as it was considered that high gradients and sharp curves would be found in all lines running through fortifications, the locomotive was made capable of running on the existing line. The sharpest curve is at the St. Mary's Barracks end, where the radius of curvature is 36ft. The conductor is constructed on the overhead trolley

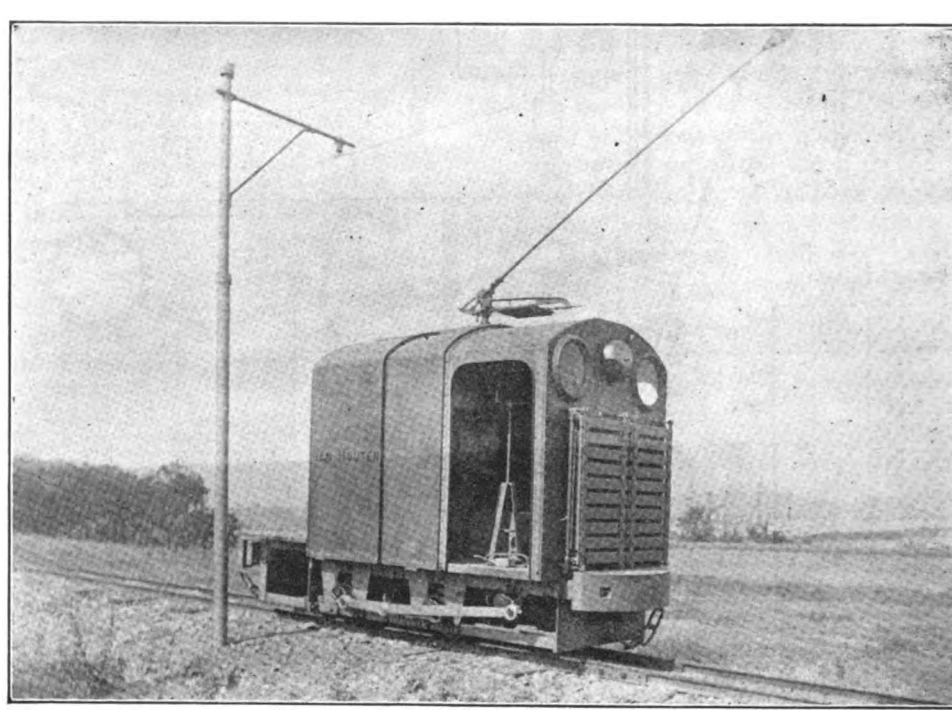

FIG. 3.—View of Locomotive on Steep Grade.

Digitized by Google

system, the rails forming the return; these are bonded together by what are known as the Chicago bond. A hole is drilled in the web of the rail, into which the two ends of the copper bond is placed. These ends are spit cylinders formed on the copper rod. A tapered steel pin is then driven into the centre of the head of the bond, which expands the copper into intimate contact with the rails. The trolley wire or main conductor is supported for the most part on brackets from poles at the side of the track, and at the curves the usual overhead construction has been followed. Owing to several arches to be passed under, the height of the trolley wire varies very much, as will be seen from the small shackles, etc., have been supplied partly by the General Electric Company of America and partly by R. Blackell. The wire itself is of No. 0 gauge, and was supplied by T. Smith and Co., of Halifax. A swivelling trolley bar is also used, which allows of the position of the trolley wire relative to the centre of the track being varied considerably. The whole of the erection of this line was carried out by the electrical school staff, which seems to contain a representative of every branch of engineering.

Locomotive.—The various details of the locomotive now in use can be seen from Fig. 1, while Fig. 3 is a perspective view of the locomotive standing on the steep grade. As will be gathered from these views, the reduction of 8 to 1

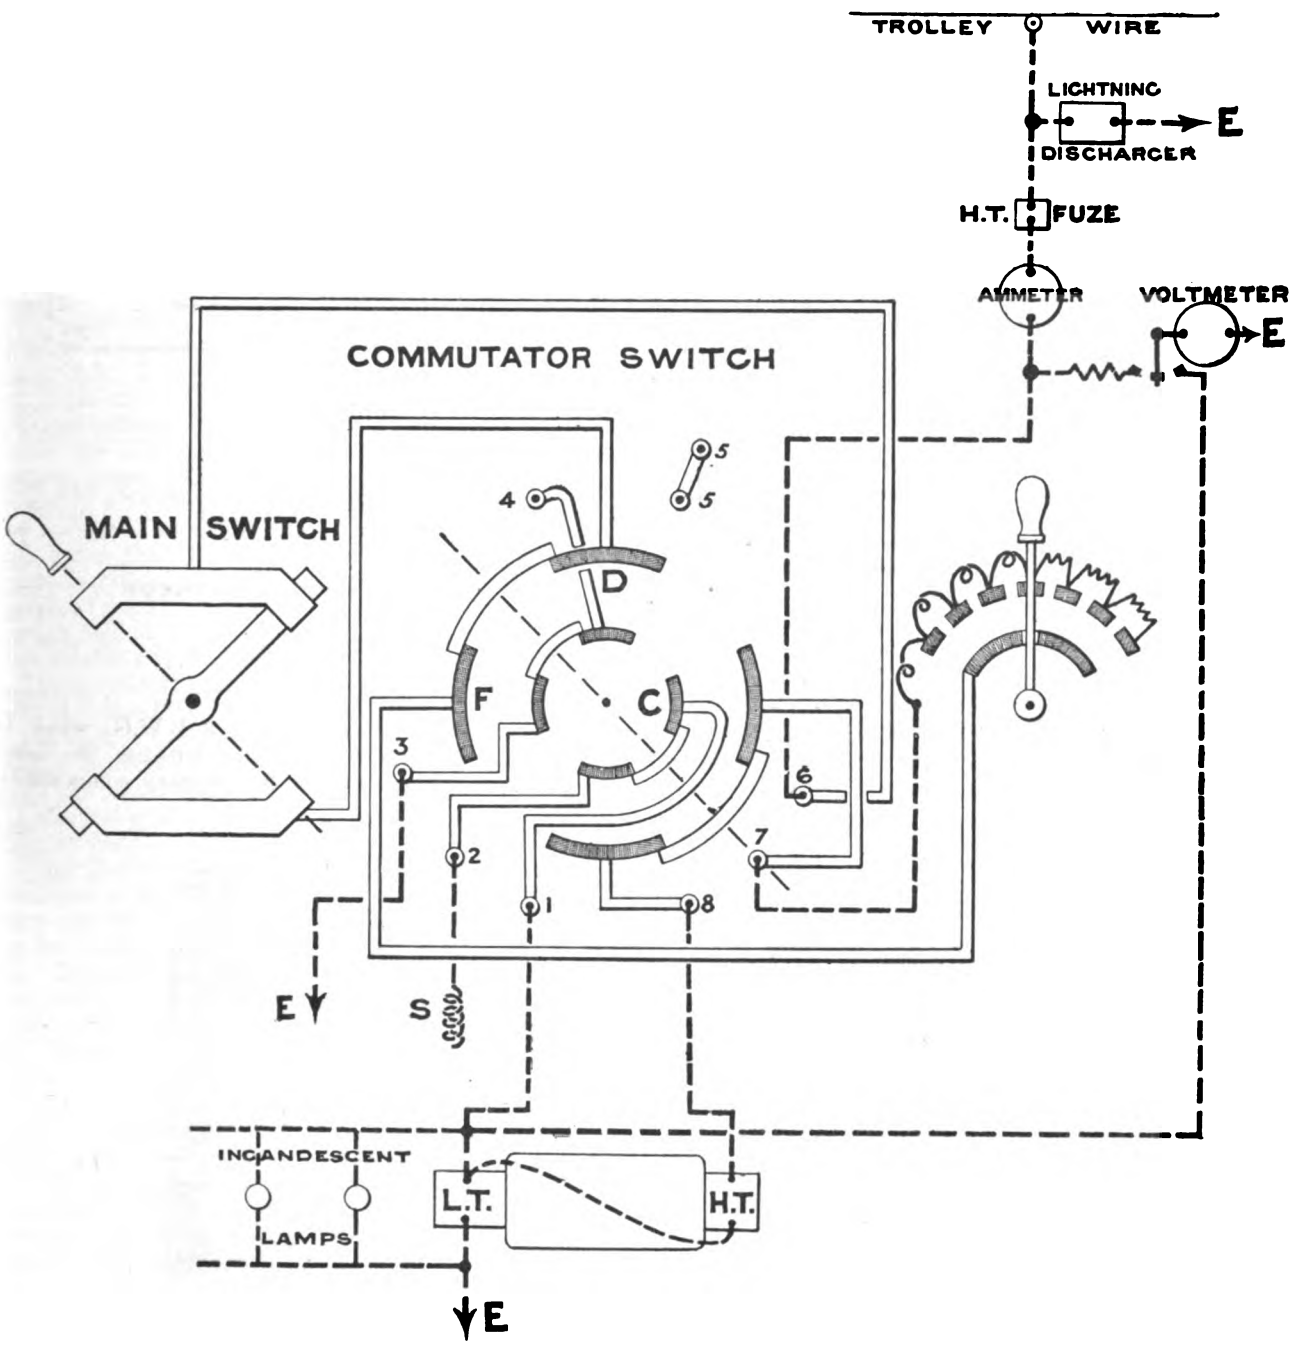

FIG. 4.—General Connections

general view in Fig. 1. A spring pole (Fig. 2), devised by Major Bagnolds, is used on the dockyard portion of the lines. In these, as can be seen from the illustration, the arm carrying the trolley wire is hinged on the pole and supported in its horizontal position by an adjustable spring. This allows the wire to give a little to the collector, and prevents the tendency of the trolley to jump when passing the points of support.

The bracket poles consist of wrought-iron tubing, tapering from 3in. to 4in. diameter, which were taken from some of the plant supplied for the abandoned Suakim railway; these, in a few instances where extra height is required, are set in old smooth-bore guns. The trolley-wire fittings, is effected by worm gearing running in oil in a cast-iron case. The worm wheel is connected to the driving wheels by connecting rods, as shown. The desire to keep these connecting rods as nearly horizontal as possible, results in the motor being slightly tilted. These driving wheels are 1ft. 10in. diameter, the distance between the centres being 3ft. 6in. The worm-wheel shaft is not rigidly connected to the motor, and all the thrust is taken by the two bearings in the worm case. The driving coupling (C, in Fig. 1) consists of two flanges having projecting pins on their adjacent faces. The pins are on different radii, and are connected together by a leather strap. When this strap is removed, the flange keyed to the motor shaft is perfectly

Digitized by Google

free to revolve, so that the motor-generator can be used for supplying search-light apparatus. The motor has the Manchester type of field, but is Gramme wound. The wound with 512 turns of No. 10 B.W.G., connected to a 64 part commutator, the calculated armature resistance being 0·222 ohm. The low-voltage secondary circuit is

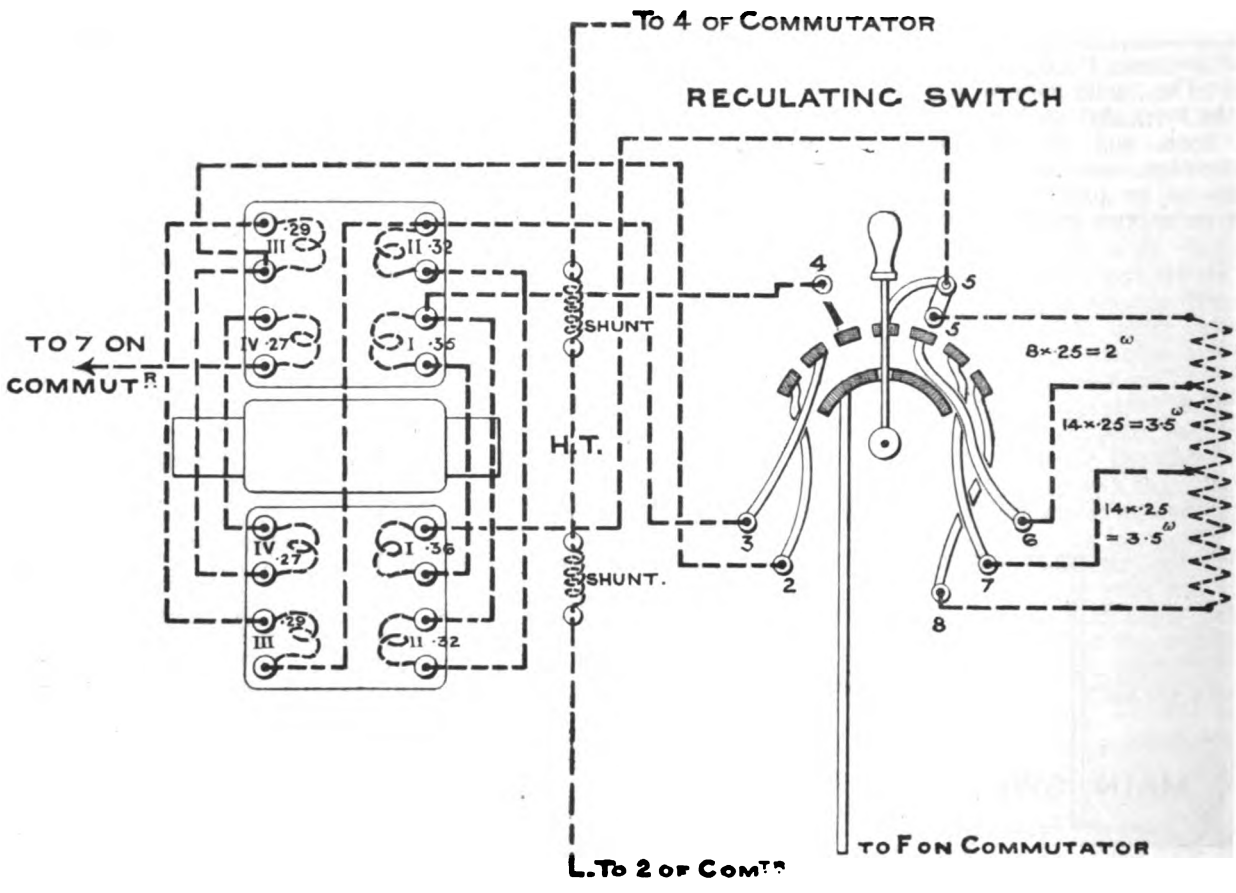

Fig. 5.—Diagram of Regulation Connections.

ratio of number of turns in the two windings is 1 to 4, so that with the connection shown in Fig. 4 the voltage in the high-tension commutator is approximately four-fifths of that

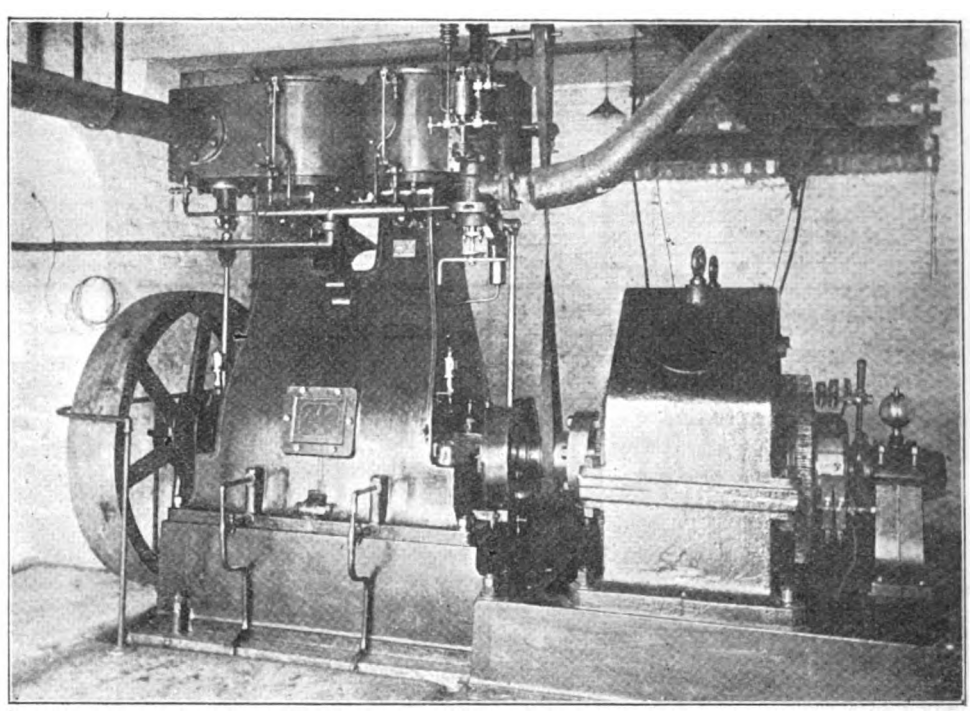

Fig. 6.—View of Engine-house.

of the line—*i.e.*, 320 volts. The voltage, then, at no load on the low-tension commutator is 80 volts.

The following are the details of the windings of the motor-generator. The primary circuit of the armature is

The resistance of this armature circuit is 0·018 ohm. The shunt winding of the field magnet consists of 772 turns of No. 15 B.W.G. and 2,290 turns of No. 14 B.W.G. in series, or 3,062 turns in all, having a resistance of 14·5

Digitized by Google

ohms when hot. The series wire on the field is No. 7 B.W.G., 432 turns being provided, and wound in four sections, whose resistances are as follows:

Sections, Fig. 5.	Resistance in ohms.
I.	0·71
II.	0·64
III.	0·58
IV.	0·54
Total	2·47

The field thus has two windings, both shunt and series, the latter being used for purposes of regulation, as shown in Figs. 4 and 5. The switch gearing is contained in a cast-iron case, S, supported over the centre of the motor (Fig. 1). There are two handles, one on either side of this—the one to make or break the circuit and to reverse the motor, and the other for regulating purposes. These two handles are made interlocking, so that the switching and reversing handle can only be moved while the regulating handle is on the last contact, which puts all resistance in. Also the regulating handle is locked when the current reversing the commutator switch is vertical—*i.e.*, in the off position.

From the diagram the connection will be readily followed with a little care. The added resistance in starting is nine ohms, which is cut out by the first three steps of the regulating switch. The next steps increase the speed by cutting out series-turns. When the machine is being used for a constant-current transformer the projector is connected across the L.T. commutator, as shown in Fig. 4, by incandescent lamps. The terminal voltage here will vary considerably with the load, but it acts in a similar manner to the resistance usually placed in series with the projector, and hence the drop is not objectionable. The rate of transformation is not dependent on the speed, and it is found, as would be expected, most economical to run with a weak field at high speeds. Then the resistance in the high-tension side is small.

The locomotive has now been in use for some time, and has been christened the "Van Houten," because, according to one of the staff, it is "the best and goes farthest." Its total weight is about five tons, and when loaded with four tons more the motor takes about 450 amperes at 350 volts on the steepest grade. The speed then is from four to five miles an hour.

Power Station.—The power station (Fig. 6) is situated in the casemates of St. Mary's Barracks. In one of the casemates there are two 20-h.p. (nominal) locomotive-type boilers—one by Ruston and Proctor, and the other by Robey and Co. These boilers are worked at 120lb. pressure, are each equipped with an injector and a feed-pump, and feed into a 4in. wrought-iron steam-main supplied by Messrs. Willans and Robinson. The pipes of this main have "loose" flanges, and are jointed with copper rings.

In an adjoining casemate is located a 42-unit direct-coupled generator, of the Kapp type, supplied by Messrs. Johnson and Phillips. The dynamo, which is compounded, is of the four-pole type, with drum armature, and yields 105 amperes at 400 volts. This dynamo is driven direct by a vertical compound 60-h.p. semi-enclosed engine, by Robey and Co., at a speed of 200 revolutions per minute. The engine is governed on the throttle by a Pickering governor.

A compact overhead traveller, to lift two tons, is located above the dynamo, the pistons and rods of the engine being dealt with by ordinary lifting tackle through a trapdoor in the floor above. This is, I believe, the only slow-speed direct-coupled generating plant for electric traction in this country. It is of specially robust construction, and although it has occasionally been pulled up pretty smartly by "shorts," no damages whatever have resulted.

A handsome switchboard completes the installation of the power station. The switches and instruments are by the Westinghouse Company, and are of their standard traction types. The marble panels of the board are neatly set in a T-iron frame, to which they are secured by half-round brass filleting and bolts. The lightning dischargers are of the Wirt "charred wood" pattern, and the shunt coil of the generator is protected by a Steele's patent "potential arrester."

Great credit is due to the staff at the electrical school for this development of electric traction for military purposes, and especially to Major Bagnolds, who has boldly tackled and overcome the numerous hitches inevitably connected with pioneer work. The whole of the generating plant has been erected by his staff, and the fireproof construction of the switchboard was entirely designed and carried out at Chatham.

A PORTABLE MAGNETIC-FIELD TESTER.*

BY PROF. W. E. AYRTON, F.R.S., AND T. MATHER.

In June, 1892, the authors described a portable ballistic galvanometer of the moving-coil type before the Physical Society of London,† but owing to delay in the manufacture the instrument was not ready in time to be shown at the meeting. Since that time many experiments have been carried out with the instrument then described, and the galvanometer has been used to map out the stray fields of various dynamos, and to explore the magnetic fields in the neighbourhood of switchboards of electric light stations.

This first instrument possessed several structural defects, but the most serious faults experienced were, first, inconstancy of zero, and, second, a considerable want of proportionality between quantity and swing—or strength of field and swing of the needle—a proportionality which theoretically should hold for all angles of whatever magnitude. Eventually both these difficulties were traced to magnetism in the suspended coil, a property which, although every care may be taken to prevent contamination of the material with iron, is very difficult to eliminate. After much experimenting, with a view to avoiding traces of magnetism in the suspended parts of swing-coil galvanometers, a satisfactory method was devised early in 1894, and a description of a reflecting galvanometer fitted with an improved coil appeared in the technical papers in the autumn of that year.‡ Meanwhile, an improved form of the portable ballistic galvanometer had been prepared, in which the details of construction were considerably modified, so as to make the working parts more accessible, and an improved shape of coil was employed.

FIG. 1.

For ballistic galvanometers the best shape of the cross-section of the moving coil is not the same as that for a current galvanometer, for whilst a current instrument should have a coil whose section approximates to two circles touching one another, a ballistic instrument is improved by using a sector-shaped coil of narrow angle, as shown in Fig. 1.

The instrument as now made is shown in Fig. 2, whilst Fig. 3 gives a sectional plan. A circular base provided with levelling screws carries a C-shaped magnet, M (Fig. 3), between the poles of which the coil, C, is suspended. The discharges are led into and out of the coil by the suspensions, one being a straight phosphor-bronze strip and the other a spiral surrounding the straight strip. Both suspensions are attached to an ebonite head near the top of the central tubes, this head serving the purpose of zero adjustment; and the arrangement is such that the whole of the suspended parts can be readily withdrawn.

The arm carrying the suspension head overhangs the scale, so as to permit of the pointer making one or more complete revolutions, and in this way an instrument having a very long range is obtained. For example, the body of the instrument shown in Fig. 2 has a diameter of 4in., and the length of the scale, reckoning only one revolution of the pointer, is about 11in. As it is quite possible to use 1½ or 2 revolutions without straining the suspensions unduly, we have here an instrument with a scale as long as that of an ordinary reflecting galvanometer (18in.) in a very com-

* Paper read at the meeting of the British Association at Ipswich

† *Electrical Engineer*, June 14, 1892.

Digitized by Google

pact form. To increase the range of the instrument still further, and to make the instrument suitable for measuring the stray magnetic field in close proximity to dynamos, pole-pieces, etc., a switch, S (Fig. 3), is arranged to put a resistance coil, R, in series with the suspended coil, thus multiplying its range by 10. The same switch, when moved to the position marked O F F, breaks the circuit of the instrument and lifts a spring, L, which clamps the coil. A short-circuit key, K, on the front of the galvanometer is used to bring the pointer to rest, for when this is pressed the motion of the coil becomes aperiodic.

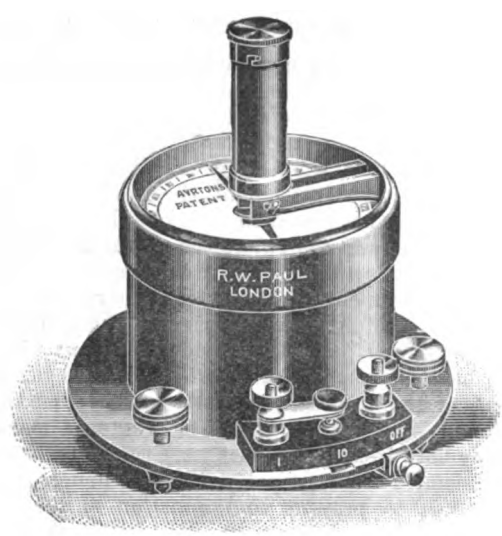

FIG. 2.

The scale of the instrument is divided into 200 parts, and as a field tester the sensibility is such that with an appropriate test coil the scale reads off directly the strength of field in C.G.S. units.

For some purposes it is convenient to have the scale graduated in microcoulombs, in which case, besides reading the quantity directly, the swing of the instrument multiplied by the total resistance of the galvanometer circuit measures

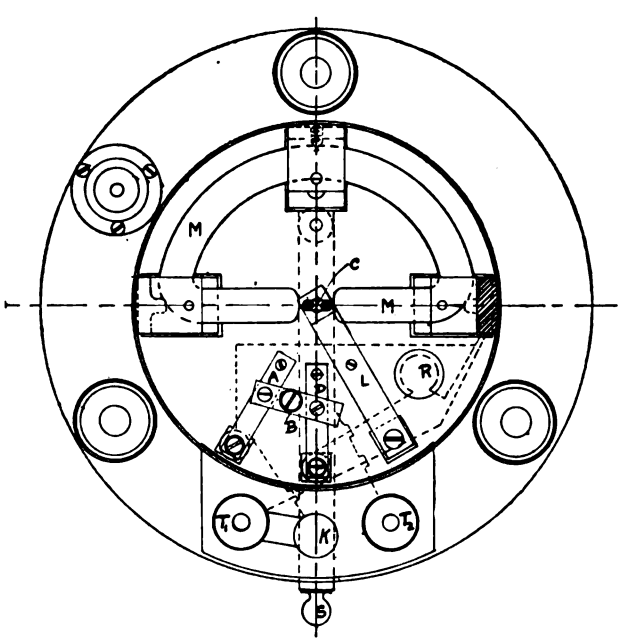

FIG. 3.

the total change of induction through that circuit. Such a scale is useful in testing iron for permeability, etc., for by suitably arranging the resistance of the circuit the scale reading can be made to read off $\mathfrak{B}$, the induction density, directly.

THEORY OF PORTABLE FIELD TESTER.

Let H = strength of magnetic field in C.G.S. units;
n = number of turns in coil;
r = mean radius in centimetres of coils projected on medial plane;
l = mean length of each coil, supposed rectangular;

Let I = moment of inertia of moving parts;
ω = angular velocity imparted to coil by discharge;
a = torque exerted by suspension when twisted through unit angle;
N = total change of flux through circuit;
R = resistance of the circuit;

Then, assuming that the plane of the coil is parallel to the field of magnet when the discharge passes, we have—

Moment exerted by the coil at any instant

$$= 2\,r\,l\,n\,\mathrm{H}\,\frac{d\,\mathrm{N}}{d\,t}\,\frac{1}{\mathrm{R}} \quad . \quad . \quad . \quad . \quad (1)$$

$$= y\,\frac{d\,\mathrm{N}}{d\,t} \text{ (say)} \quad . \quad . \quad . \quad . \quad . \quad . \quad (2)$$

therefore angular impulse $= \int y\,\frac{d\,\mathrm{N}}{d\,t}\,d\,t \quad . \quad . \quad . \quad . \quad (3)$

$$= y\,\mathrm{N} \quad . \quad . \quad . \quad . \quad . \quad . \quad (4)$$

This must be equal to the angular momentum imparted to the coil,

hence $$\mathrm{I}\,\omega = y\,\mathrm{N} \quad . \quad . \quad . \quad . \quad . \quad . \quad (5)$$

Now, the energy stored in the coil at the completion of the discharge is

$$\frac{\mathrm{I}\,\omega^2}{2}, \text{ and is therefore} = \frac{\mathrm{I}}{2}\left(\frac{y\,\mathrm{N}}{\mathrm{I}}\right)^2 \text{ from (5)}$$

$$= \frac{y^2\,\mathrm{N}^2}{2\,\mathrm{I}} \quad . \quad . \quad . \quad . \quad . \quad . \quad . \quad (6)$$

Now, all this energy is expended in twisting the suspensions through an angle, ϕ, where ϕ is the swing of the pointer. But the work done in the process is

$$\int_0^{\phi} a\,\theta\,d\,\theta,$$

$$= \frac{a\,\phi^2}{2} \quad . \quad . \quad . \quad . \quad . \quad . \quad (7)$$

Equating (6) and (7) we have

$$\frac{a\,\phi^2}{2} = \frac{y^2\,\mathrm{N}^2}{2\,\mathrm{I}},$$

from which $$\phi = \pm\frac{y}{\sqrt{a\,\mathrm{I}}}\,.\,\mathrm{N};$$

i.e., ϕ is proportional to N.

Appended we give a table showing the relative swings produced by discharging a given quantity of electricity through a given length of wire wound into coils of various shapes. From this it will be seen that the long narrow coil has considerable advantage over common shapes as regards sensibility. At the same time, it permits of much greater range than the forms which necessitate the use of a central core in order to obtain the requisite strength of field to give good shielding from external disturbing fields. The use of a narrow coil also enable swings to be taken in either direction without reducing the range, whereas instruments with cores necessarily have their maximum range of 180deg. reduced to something less than 90deg. if arranged to read either right or left of zero.

The standard exploring coil used with this instrument is shown in Fig. 4. The coil, C, is fixed to a spindle, A,

Digitized by Google

which is able to rotate through 180deg. in the handle, B. A spring attached to it inside the handle gives it the impulse necessary. The coil is first set back and then engages with a click which is released by the trigger, T.

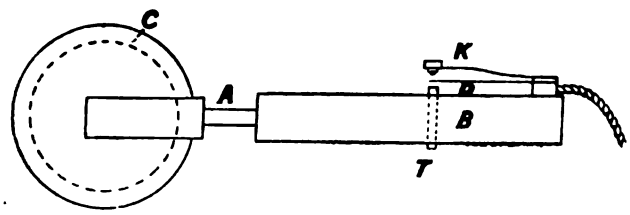

FIG. 4.

This trigger is actuated by the pressure on the key, K, which after closing the galvanometer circuit depresses the lower spring, D, and releases the coil. The area and number of turns in the coil, C, are so calculated that the deflections in the galvanometer give induction in C.G.S. units per square centimetre.

SOME EXPERIMENTS MADE WITH LORD KELVIN'S PORTABLE ELECTROMETER.*

BY ARTHUR SCHUSTER, F.R.S.

Experiments made during a recent journey to Switzerland have shown to the author how easily observations on atmospheric electricity are performed by means of Lord Kelvin's portable electrometer. The instrument is easily carried in a knapsack to almost any place within reach of the mountaineer, and the observations are readily made in a short space of time in the way long ago described by Lord Kelvin. The object of the experiments was to learn, if possible, whether the electric force at great heights is sensibly different from that at the sea-level. But owing to the difficulty of comparing together observations made in valleys with those made on mountain peaks, the measurements made during the past month were entirely of a tentative character more for the purpose of gaining experience with the instrument and to obtain guidance for future work than with a view of bringing home definite results. The numbers which are given in this brief account have only a relative value, as they are referred to an arbitrary unit. A number of experiments made in fine weather in the centre of a small meadow in front of the hotel at Pontresina gave on the average about 30 for the electric force, which is smaller than that found in England under similar circumstances. Thus, on September 13, at Ipswich, on a plot of grass rather more sheltered by surrounding meadows than the Pontresina meadow, the author found the electric force to be over 80. On the so-called Diarlezza Pass the number found was as high as 147, while on the Isola Pirs, a rocky island, projecting well out of the surrounding glacier, it was 116. On August 19 the instrument was taken to the top of the Glushaint (12,000ft.), which consists of a ridge of rocks just wide enough for one man to stand upon. The electric force reached the number 816, while on a snowfield a few hundred feet below the top the force was only 170. The top of the Schafberg gave 357 for the electric force. On the Morteraheb glacier the numbers were, as a rule, very low, except on one occasion when a strong downward wind was blowing, but even then the force only went up to 42. Half-a-mile below the snout of the glaciers the numbers found were very irregular, and seemed to depend on the direction of the wind. On one occasion, when the wind was frequently changing, being sometimes up and sometimes down the valley, a negative electrification was observed whenever the current of air was from the glacier. This was probably due to negative electrification caused by the glacier stream, in a way similar to that in which a similar electrification is produced by waterfalls.

The daily variation was observed on one day by taking observations every half-hour from nine to twelve o'clock and every hour in the afternoon until seven o'clock. A principal maximum of 36 was observed at 11 a.m. The numbers then fell irregularly till four o'clock, when the electrification was only 14. After that time it rose to 31 at 5 p.m. and 29 at 6 p.m., and fell to zero at 7 p.m. The wind, which had been blowing up the valley all day, changed in direction between the two last observations, and was blowing downwards at seven o'clock. The author does not draw any conclusions from his observations, but does not believe that a mere difference in the configuration of the ground is sufficient to account for the great differences in electric force observed.

* Abstract of paper read at the meeting of the British Association at Ipswich.

SOME LESSONS IN TELEPHONY.*

BY A. R. BENNETT, M.I.E.E.

In 1846 Mr. J. C. Bourne, in his history of the Great Western Railway, wrote: "It is a well-established truth in the history of trade and commerce that the traffic between two cities or countries will increase in proportion to the facilities of communication afforded, or to the speed, security, and cheapness with which such communication can be effected."

The truth of this proposition had been demonstrated before Bourne's time in respect to common roads and waterways; since, experience has shown that no town can prosper unless it be connected with the railway system of the country. In the beginning, several towns, by spending large sums in opposing Railway Bills, succeeded in keeping off the main lines of communication, but the magnitude of the error has long since been manifest, and great efforts have been made, not always successfully, to repair it.

Bourne's axiom may nowadays be admitted to embrace telegraphic and telephonic facilities, for places wanting these are at a great disadvantage as compared with more fortunate neighbours. If commerce may be held to constitute the life-blood of a modern nation, roads, railways, and waterways are the arteries through which this blood is conducted, while telegraphs and telephones may be compared to the nerves which feel out and determine the course of that circulation which is a condition of national prosperity. Given two nations, equal or nearly so in natural resources and in the talents and industry of their inhabitants, that one will succeed the better in commerce which possesses the most extended and cheapest facilities for transport and general intercommunication.

It has recently been demonstrated that the United Kingdom is deficient in at least two of these essentials—railways in their branch or feeder form, and telephones, which are the natural feeders of the telegraphs. Why this is so may best be discovered by ascertaining by what means, technical or economical, those nations which have most conspicuously outstripped us have attained their superiority. For the purposes of this paper, in which is considered the telephonic branch of the question, the countries of Europe have been divided into three groups: (1) well telephoned; (2) indifferently telephoned; (3) badly telephoned.

A country may most properly be said to be well telephoned when its smaller towns and villages enjoy facilities, for the existence of a few large exchanges in the capital and chief towns does not entitle it to that distinction. For instance, France, Russia, and Portugal all possess good exchanges in their capitals, but are nevertheless badly telephoned as a whole, since their smaller towns and villages are excluded from the circle.

On the other hand, we find that the Grand Duchy of Finland, under the same crown as Russia, but enjoying a different system of administration, is distinctly well telephoned. Its area exceeds that of the United Kingdom, although the greater part of its surface consists of lake, forest, and waste; its staple industries are fishing and agriculture, yet a telephonic map of Finland discloses a veritable network of lines. All the towns and many of the villages possess exchanges, while the capital, Helsingfors (population 65,000), is one of the best-telephoned cities in the world. Last year there were 198 exchanges in Finland, or one to each 12,626 inhabitants. In the United Kingdom there were but 578 exchanges, or one to each 65,537 inhabitants. In proportion to its population, Finland had therefore more than five times as many centres of telephonic activity as the United Kingdom. Even the people of the Aland Islands, in the middle of the Baltic, find a telephone exchange so well worth paying for at the rates which are found remunerative by the exploiting company, that in Mariehamn, the capital, there is an exchange telephone to every 13 inhabitants. In fact, Mariehamn is entitled to the distinction of being the best-telephoned town in the world. Another Finnish town, Viborg (population 22,344), has an exchange telephone to every 33 inhabitants, and other towns have one to 36, 37, 39, and 40.

* Paper read at the meeting of the British Association at Ipswich.

Digitized by Google

Norway is, however, the best-telephoned country on the whole. It has a population of 2,000,000, and has little to rely upon in the world's struggle but agriculture, forestry, and fishing. Seventy per cent. of its total area is uncultivable, and another 24 per cent. is forest. It has but half-a-dozen towns, the bulk of the population residing in widely-scattered villages. Yet it

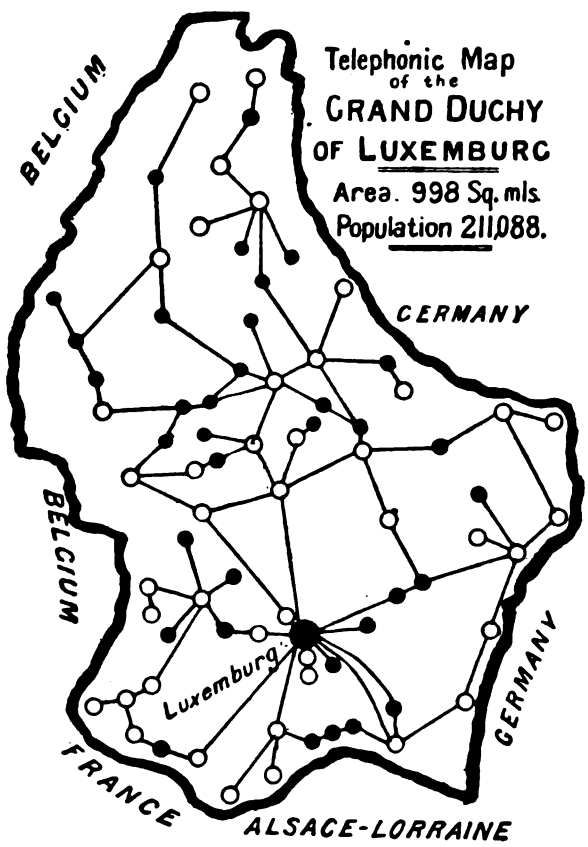

FIG. 1.

possesses no fewer than 256 telephone exchanges, or one exchange to each 7,812 inhabitants—more than 8½ times the number in the United Kingdom in proportion to population.

Sweden, which takes the second place in the list of well-telephoned countries, possesses greater resources than Norway. It has a population of not quite 5,000,000, one-half of which is dependent on agriculture. Eighty per cent. of the people live outside the towns. A radius of 43½ miles round Stockholm, equal to 5,945 square miles, is unquestionably the best-telephoned bit of country in the world. Almost every village possesses two competing telephone exchanges, while rival systems of trunk lines place the whole of this large area in practically instantaneous communication.

Denmark, with its population of 2,250,000, and its staple industries of agriculture and dairy farming, takes an honourable place, having 152 telephone exchanges within its borders, or one to every 14,639 inhabitants.

The four foregoing countries form a class by themselves. Their telephonic development has been due almost exclusively to companies and co-operative societies. In Sweden the State has of recent years assumed an important position in respect to telephony, but its proceedings and tariffs have been based upon the previously-established procedure and tariffs of the companies whose systems it found in operation. In the two next instances the development attained is due wholly to the fostering care of the respective States.

Switzerland has a population of 3,000,000, which is served by 155 telephone exchanges, or one to every 19,355 inhabitants. All its towns and many of its villages possess telephone stations and are connected by trunk lines. The Grand Duchy of Luxemburg contains 998 square miles, which is also precisely the area of Dorsetshire. The respective populations are 211,088 and 194,517. Agriculture is the staple industry of Luxemburg, as it is of Dorset. We find, however, that while Luxemburg possesses 59 telephone switchrooms within its borders, or one to each 3,577 inhabitants, Dorset has only three—Dorchester, Weymouth, and Poole—or one to each 64,839. Luxemburg had last year 1,315 exchange lines; Dorset, at the present moment, possesses about 70. In Luxemburg, there is an exchange telephone to every 160 souls; in Dorset, one to 2,778. Every town and village of Luxemburg is in telephonic communication with the capital and with each other. The accompanying maps, Figs. 1 and 2, exhibit the different stages of development attained in these two equal areas. And yet many counties are worse off than Dorsetshire is.

This completes the list of the European countries which are well telephoned, and constitute Group I. The least favourable result in this group is 328 persons per exchange telephone. A considerable jump must be made in order to reach the best country of Group II. This is the Imperial German Post Office territory, which comprises the whole of the German Empire except Bavaria and Wurtemberg. Within its limits there was last year one telephone to every 449 inhabitants. It is noteworthy to remark that the comparatively good position taken by Germany is due to the fact that Berlin, Hamburg, Frankfort-on-Maine, and other chief towns possess very large exchanges, Berlin and Hamburg being amongst the largest in the world, even Hamburg (population 622,530) having a larger number of subscribers than London (population 5,600,000). But the small towns and villages are not developed, and rural intercourse by telephone is practically non-existent. The reason is that the German Post Office has a uniform tariff, applicable equally to the capital and to the smallest village, which, although reasonable for Berlin, is prohibitive for the country folk. The results obtained in Bavaria and Wurtemberg are not dissimilar.

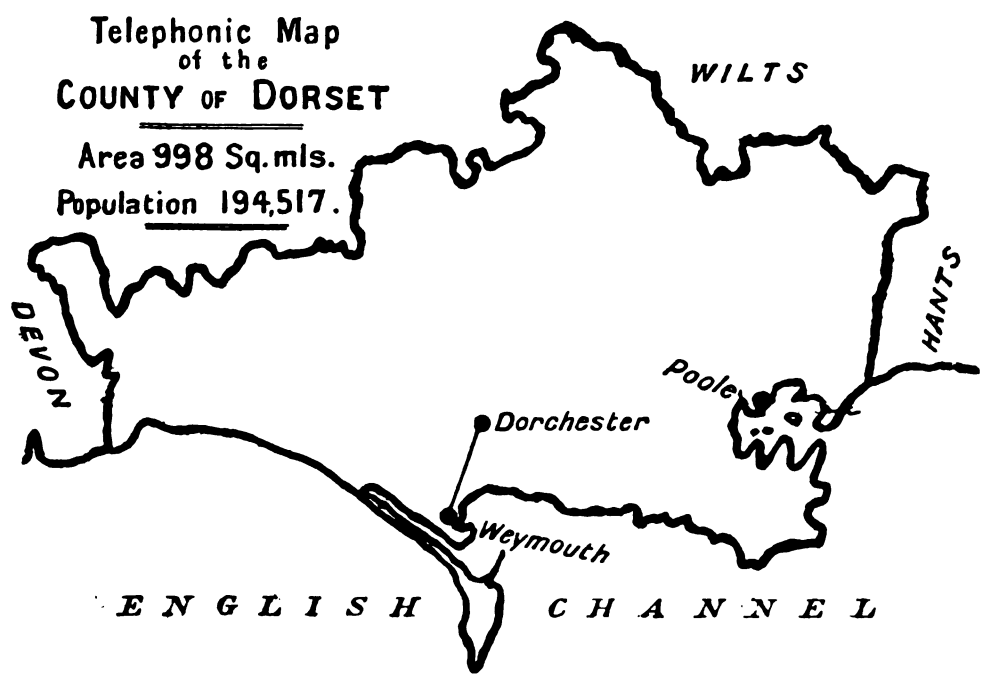

FIG. 2.

Wurtemberg has a lower initial tariff than the Imperial Post Office, but is hampered with restrictions which operate against rural development. The United Kingdom comes next in order of merit, with one exchange telephone to every 636 persons. These figures, like the continental ones, refer to last year. The ratio has improved since then both at home and abroad, but the relative positions remain unchanged.

TABLE A.

Order of merit.	Country.	Population.	Number of exchange telephones.	Number of persons to each exchange telephone.	Characteristics of management.
	Group I.				
1	Norway	2,000,917	13,943	144	Very low rates. Local management of exchanges. Good rural intercourse. No competition.
2	Sweden	4,784,981	32,602	147	Very low rates. Local management of exchanges in part. Good rural intercourse. Competition.
3	Luxemburg	211,088	1,315	160	Very low rates. Central management, but with delegated control in some cases to local authorities. Good rural intercourse. No competition.
4	Switzerland	3,000,000	17,422	172	Ditto ditto ditto.
5	Denmark	2,185,335	10,325	211	Very low rates. Local management of exchanges. Good rural intercourse. No competition.
6	Finland	2,412,135	7,351	328	Very low rates. Local management of exchanges. Good rural intercourse. Competition.
	Group II.				
7	Imperial German Post Office Territory	41,796,966	93,131	449	Fair rates for urban subscribers in large towns; high rates in small towns. Highly centralised management. Bad rural intercourse. No competition.
8	Bavaria	5,594,982	12,400	451	Ditto ditto ditto.
9	Wurtemberg	2,036,522	4,430	459	Low rates for urban subscribers, but with regulations tending to restrict suburban and rural intercourse. Centralised management. No competition.
10	United Kingdom	37,880,764	59,569*	636	High rates, with regulations unfavourable to development outside towns. Local management in part. Practically no competition.
11	Holland	4,669,576	7,263	643	High rates in three chief towns; low rates elsewhere. Management chiefly centralised. Bad rural intercourse. No competition.
12	Belgium	6,136,444	8,757	700	High rates in large towns; low rates of recent origin in small towns. Centralised management. Indifferent rural intercourse. No competition.
	Group III				
13	France	38,343,192	26,772	1,432	High rates; subscribers also pay capital cost of their installations, except in Paris and Lyons. Centralised management. Bad rural intercourse. No competition.
14	Spain	17,800,000	10,984	1,618	High rates in large towns. Recently introduced reduced tariff for smaller towns. Local management. Bad rural intercourse. No competition.
15	Austria	23,895,413	14,574	1,640	Fair rates, but subscribers pay capital cost of their installations. Centralised management. Bad rural intercourse. No competition.
16	Italy	30,535,848	12,067	2,530	High rates in large towns, except in Rome, where competition exists; low rates in Rome and in small towns, but under strict Government supervision. Bad rural intercourse. No competition except in Rome.
17	Hungary	17,463,473	5,563	3,139	High rates in towns; very low rates in villages, but combined with regulations which tend to restrict communication between towns, suburbs, and villages. Partly local management. No competition.
18	Portugal	5,000,000	1,483	3,371	Exchanges only in Lisbon and Oporto. Fair rates. No rural intercourse. No competition.
19	Russia	97,151,789	7,415	13,102	Highest rates in Europe in chief towns; high rates in smaller towns. Partly local management under Government rules. Bad rural intercourse. No competition.

* Company, 58 367; Post Office, 1,202.

Holland and Belgium complete Group II. A wide gap intervenes between this and Group III., or badly-telephoned class. The best country of this is France, with one exchange telephone to every 1,432 persons; and the worst is Russia, which can only show one to each 13,102 inhabitants.

The foregoing facts are presented in Table A, which also gives the leading characteristics of the management in each country.

The questions naturally arise, "To what causes are such vast differences in development to be ascribed?" and "Why is the United Kingdom, with its preponderating commercial importance and unparalleled spirit of enterprise, only tenth on the list, instead of first?" A study of the table supplies the answer. It shows that telephonic development is proportional to the prevalence of the following features: (1) low rates; (2) local management; (3) facilities for rural intercourse; (4) competition.

At least three of these are characteristic of each of the six countries which compose Group I. On the other hand, they are almost completely absent from Groups II. and III., the leading characteristics of which are (1) high rates, (2) centralised management, (3) neglect of small towns and rural districts, (4) absence of competition.

The operation of low rates and competition in the direction of development is easily understood, but that of local management is not so obvious. Its importance, however, is great. No two places are precisely alike in commercial, social, or topographical features, and telephonic arrangements which suit one neighbourhood admirably are not appreciated in another where other conditions call for other plans. To meet the wants of a locality fully, it is necessary that its character should be thoroughly understood at the headquarters of management, and this, when exchanges are numerous, is not attainable. On the other hand, a Board or council of local men know the requirements of the community exactly; hence the superiority of the results presented by the Scandinavian local companies and co-operative societies. Wherever management is centralised, uniformity is aimed at as a means to economy and of saving trouble, and what appears good in the capital is apt to be imposed on every other town.

In the countries of Group I. special attention is given to small town and rural development. In Switzerland a village council, commune, or other local authority may establish and manage a telephone station in one of its own buildings, and work it with its own employees, simply paying to the State the ordinary subscription of £4. 16s. for the first, £4 for the second, and £3. 4s. for the third and subsequent years, for the privilege of a junction with the general telephone system of the country. Such stations, of which there are 129 in Switzerland, are available for the despatch and receipt of written telegrams as well as of telephone messages. The local authority is authorised to collect a small surcharge on the ordinary tariff to cover expenses incurred for wages, office, and the annual payment to the State.

In Luxemburg a similar system prevails, and is taken advantage of by 34 local authorities. The annual payment to the State for the connection of the municipal station to the general system of the country is uniformly £4 per annum.

France has adopted a similar system, but with a much higher scale of charges and with restrictions which appear irksome to the local authorities, since in 1894 only 10 municipal stations existed in the whole of France.

In the Scandivanian countries and Finland, local management has had even freer play, with the highly satisfactory result disclosed in the table. The third town of Norway, Trondhjem (population 30,000), is worked by the municipality most successfully at very low rates.

(To be concluded.)

MUNICIPAL ELECTRICAL ENGINEERS.

The number of municipal electrical engineers is rapidly increasing, and the position and status of the individual members will in the future be largely influenced by the actions of the present. It must be admitted that electrical engineers employed in the interests of municipalities have to deal with questions that do not seem of overwhelming importance to other engineers—questions, too, which hardly come within the scope of the work of existing institutions. We have more than once advocated the formation of an Association of Municipal Electrical Engineers, because neither the Institution nor kindred societies seem suited for the discussion of certain questions appealing to this one class, and to that class only. We are informed that the initiative steps have been taken to form a separate association, and it is to point out the grave mistakes that have been made in these initiatory steps that this article is written. Above all things, the officials of such a society should be, like Cæsar's wife, above suspicion, unconnected with trade matters, and absolutely unbiassed in every direction which touches upon the welfare of the members. The position of affairs we are informed, upon what seems to us the best authority, is that an honorary secretary has been elected who is in no way connected with municipal work; who is a kind of roving correspondent upon the staff of a trade newspaper; and, more than all, is a commercial traveller trying to sell the wares of his employers to the men whose society he is to represent. The business acumen of his employers and of himself cannot be overlooked. They look solely to the one result—does this man's travelling pay? He looks to that same result, for if it pays his masters it pays him. But what about the society? Do the members that are, or are to be, believe for one moment that such a man can have their interests at heart? If they believe this, they are less used to the ways of this wicked world than men of such standing and character are apt to be. It is easy to see how the members who really started the movement managed to fall into such an error. It is not the part of a commercial traveller to cry "Bagman, bagman," at all times and at all seasons, but to sink self and ultimate aims at times in order to get into the swim. The honorary secretary—which in this case means more or less the acting secretary—must in the course of his secretarial duties become cognisant of much that is in an embryonic state as regards municipal business. That, in this case, is just what the man wants, so as to be able to direct municipal enterprise through channels that will bring him in the £. s. d. A word here and a word there unconsciously dropped before "our secretary" may be unimportant in the mind of the speaker, but may give the said secretary a clue which, as a business man, he will not be slow to follow up. If an Association of Municipal Electrical Engineers is to succeed, both permanent officials and council must be unconnected with trade. No outsider of the kind we have indicated ought to have been tolerated for a moment in the councils of those taking an active part in the movement. It is just possible that the secrecy that has been observed

Digitized by Google

has been the result of this alien importation. No doubt he thinks he can keep the movement to himself till such time as it is too late to remedy the evil. He mistakes his men, and we are pretty certain that unless a change takes place in the constitution of the committee the whole matter will come to an impotent conclusion. This will be a regrettable incident in the history of the Municipal Electrical Engineers, for it will bring about a cleavage of members when what is wanted is unanimity. The being hand-and-glove with a "commercial traveller" will cause every municipal electrical engineer to be doubted by his committee. He will be thought to be recommending certain forms of apparatus, not because he believes the apparatus to be the best of its kind, but because he would like to do a good turn to "our secretary." There is in every town council and on every committee a man who, once he gets a hint of doubtful straightness, will make the engineer's life a burden, if not a shame. Similarly, no member of the committee taking steps to form the society should be connected, directly or remotely, with patents or manufacturers. There are plenty of able men outside these directions, and to these men should be entrusted the work of organisation. We trust we have said no word herein to touch the susceptibility of individuals. That forms no part of our programme. An error has been committed which ought to have been avoided, especially if what we hear is correct—that at the very first meeting the general opinion was to avoid, above all things, "trade connections."

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

LIGHT RAILWAYS.

SIR,—We were amused on reading "Dividend's" letter in your issue of Friday last *re* the Derby-to-Ashbourne light railway.

There always were, and will be, "outsiders" who know more about matters than the people who are dealing with them.

However, his statements as to this line generally seem to us about as inaccurate as is his information that we estimated the cost of the permanent-way construction at £1,000 per mile. The fact is, we estimated the cost at over £2,300 per single mile. If "Dividend" is *bonâ fide* and will communicate with us, we will supply him with a copy of the estimate made more than four months ago; but we really cannot enter into a newspaper correspondence with a person whose object does not appear to be to elicit facts, but, for reasons best known to himself, to throw cold water on the scheme.—Yours, etc.,

ALFRED DICKINSON AND CO.

120, Colmore-row, Birmingham, September, 18, 1895.

THE DUBLIN AND KINGSTOWN ELECTRIC TRAMWAY.

SIR,—I beg to call your attention to certain errors in your journal of the 13th inst. (p. 300), in the column headed "Dublin and Kingstown Electric Tramways." You mention "Mr. Robertson," secretary and manager, whereas it should be Mr. J. Clifton Robinson, electrical engineer, and also managing director of the company. I am sorry to trouble you in this matter, but small things of this kind often give rise to confusion. I shall be glad if you will correct the same.—Yours, etc., G. E. CUMMINGS.

88, High-road, Chiswick, W., September 14, 1895.

ELECTRIFICATION AND DISELECTRIFICATION OF AIR AND OTHER GASES.*

BY LORD KELVIN, MAGNUS MACLEAN, AND ALEXANDER GALT.

§ 1. Experiments were made for the purpose of finding an approximation to the amount of electrification communicated to air by one or more electrified needle points. The apparatus consisted of a metallic can 48cm. high and 21cm. in diameter, supported by paraffin blocks, and connected to one pair of quadrants of a quadrant electrometer. It had a hole at the top to admit the electrifying wire, which was 5·31 metres long hanging vertically within a metallic guard tube. This guard tube was always metallically connected to the other pair of quadrants of the electrometer and to its case, and to a metallic screen surrounding it. This prevented any external influences from sensibly affecting the electrometer, such as the working of the electric machine which stood on a shelf five metres above it.

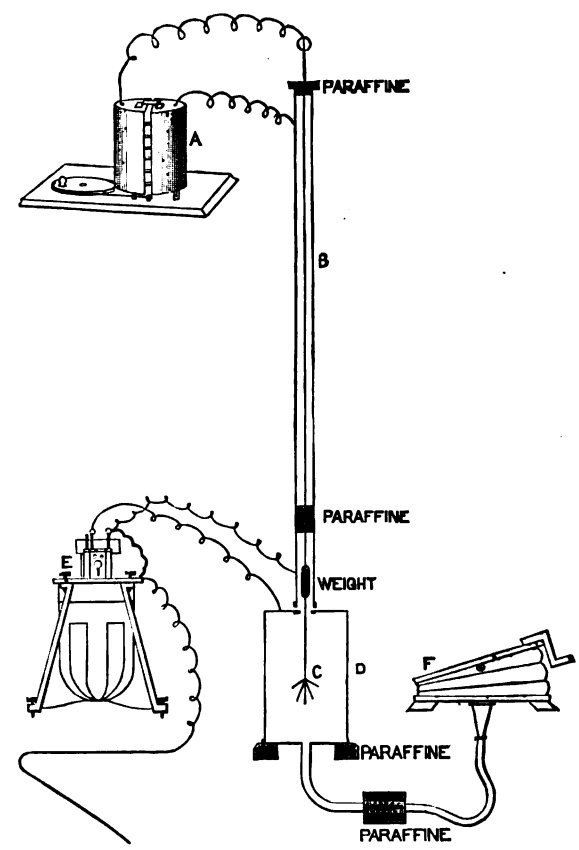

FIG. 1.—(Connected with guard screen, not shown in diagram.)

§ 2. The experiment is conducted as follows: One terminal of an electric machine is connected with the guard tube and the other with the electrifying wire, which is let down so that the needle is in the centre of the can. The can is temporarily connected to the case of the electrometer. The electric machine is then worked for some minutes, so as to electrify the air in the can. As soon as the machine is stopped the electrifying wire is lifted clear out of the can. The can and the quadrants in metallic connection with it are disconnected from the case of the electrometer, and the electrified air is very rapidly drawn away from the can by a blowpipe bellows arranged to suck. This releases the opposite kind of electricity from the inside of the can, and allows it to place itself in equilibrium on the outside of the can and on the insulated quadrants of the electrometer in metallic connection with it.

§ 3. We tried different lengths of time of electrification and different numbers of needles and tinsel, but we found that one needle and four minutes of electrification gave nearly maximum effect. The greatest deflection observed was 936 scale divisions. To find, from this reading, the electric density of the air in the can, we took a metallic disc, of 2cm. radius, attached to a long varnished glass rod, and placed it at a distance of 1·45cm. from another and larger

* Abstract of paper read at the meeting of the British Association at Ipswich.

Digitized by Google

metallic disc. This small air condenser was charged from the electric light conductors in the laboratory to a difference of potential amounting to 100 volts. The insulated disc thus charged was removed and laid upon the roof of the large insulated can. This addition to the metal in connection with it does not sensibly influence its electrostatic capacity. The deflection observed was 122 scale divisions. The capacity of the condenser is approximately $\frac{\pi \times 2^2}{4\pi \times 1{\cdot}45} = \frac{1}{1{\cdot}45}$. The quantity of electricity with which it was charged was $\frac{1}{1{\cdot}45} \times \frac{100}{300} = \frac{1}{4{\cdot}35}$ electrostatic unit. Hence the quantity to give 936 scale divisions was

$$\frac{1}{4{\cdot}35} \times \frac{936}{122} = 1{\cdot}7637.$$

The bellows was worked vigorously for 2½ minutes, and in that time all the electrified air would be exhausted. The capacity of the can was 16,632 cubic centimetres, which gives, for the quantity of electricity per cubic centimetre, $\frac{1{\cdot}7637}{16{,}632} = 1{\cdot}06 \times 10^{-4}$. The electrification of the air in this case was positive; it was about as great as the greatest we got, whether positive or negative, in common air when we electrified it by discharge from needle points. This is about four times the electric density which we roughly estimated as about the greatest given to the air in the inside of a large metal vat, electrified by a needle point and then left to itself, and tested by the potential of a water-dropper with its nozzle in the centre of the vat, in experiments made two years ago and described in a communication to the Royal Society of date May, 1894.*

§ 4. In subsequent experiments, electrifying common air in a large gasholder over water by an insulated gas flame burning within it, with a wire in the interior of the flame kept electrified by an electric machine to about 6,000 volts, whether positively or negatively, we found as much as $1{\cdot}5 \times 10^{-4}$ for the electric density of the air. Electrifying carbonic acid in the same gasholder, *whether positively or negatively*, by needle points, we obtained an electric density of $2{\cdot}2 \times 10^{-4}$.

§ 5. We found about the same electric density ($2{\cdot}2 \times 10^{-4}$) of *negative* electricity in carbonic acid gas drawn from an iron cylinder lying horizontally, and allowed to pass by a U-tube into the gasholder without bubbling through the water. This electrification was due probably not to carbonic acid gas rushing through the stopcock of the cylinder, but to bubbling from the liquid carbonic acid in its interior, or to the formation of carbonic acid snow in the passages and its subsequent evaporation. When carbonic acid gas was drawn slowly from the liquid carbonic acid in the iron cylinder placed upright, and allowed to pass, without bubbling, through the U-tube into the gasholder over water, no electrification was found in the gas unless electricity was communicated to it from needle points.

§ 6. The electrifications of air and carbonic acid described in Sections 4 and 5 were tested, and their electric densities measured by drawing from an air-pump a measured quantity of the gas† from the gasholder through an indiarubber tube to a receiver of known efficiency and of known capacity in connection with the electrometer. We have not yet measured how much electricity was lost in the passage through the indiarubber tube. It was not probably nothing; and the electric density of the gas before leaving the gasholder was no doubt greater, though perhaps not much greater, than what it had when it reached the electric receiver.

§ 7. The efficiency of the electric receivers used was approximately determined by putting two of them in series with a paraffined tunnel between them, and measuring by means of two quadrant electrometers the quantity of electricity which each took from a measured quantity of air drawn through them. By performing this experiment several times, with the order of the two receivers alternately reversed, we had data for calculating the proportion of the electricity taken by each receiver from the air entering it, on the assumption that the proportion taken by each receiver was the same in each case. This assumption was approximately justified by the results.

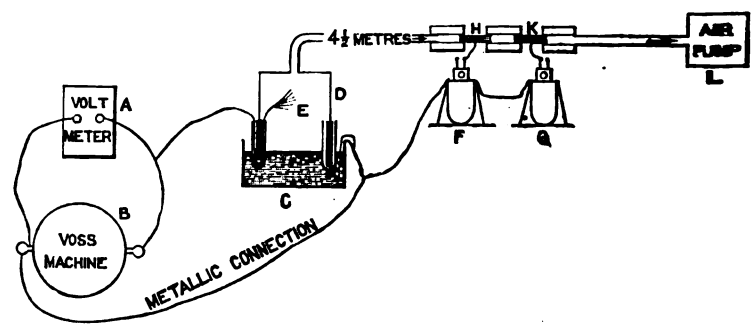

FIG. 2.

§ 8. Thus we found for the efficiencies of two different receivers respectively 0·77 and 0·31 with air electrified positively or negatively by needle points; and 0·82 and 0·42 with carbonic acid gas electrified negatively by being drawn from an iron cylinder placed on its side. Each of these receivers consisted of block tin pipe, 4cm. long and 1cm. diameter, with five plugs of cotton wool kept in position by six discs of fine wire gauze. The great difference in their efficiency was no doubt due to the quantities of cotton wool being different, or differently compressed in the two.

§ 9. We have commenced and we hope to continue an investigation of the efficiency of electric receivers of various kinds, such as block tin, brass, and platinum tubes from 2cm. to 4cm. long, and from 1mm. to 1cm. internal diameter, all of smooth bore and without any cotton wool or wire gauze filters in them; also a polished metal solid, insulated within a paraffined tunnel. This investigation, made with various quantities of air drawn through per second, have already given us some interesting and surprising results, which we hope to describe after we have learned more by farther experimenting.

§ 10. In addition to our experiments on electric filters we have made many other experiments to find other means for the diselectrification of air. It might be supposed that drawing air in bubbles through water should be very effective for this purpose, but we find that this is far from being the case. We had previously found that non-electrified air drawn in bubbles through pure water becomes negatively electrified, and through salt water positively. We now find that positively electrified air drawn through pure water, and negatively electrified air through salt water, has its electrification diminished but not annulled, if the primitive electrification is sufficiently strong. Negatively electrified air drawn in bubbles through pure water, and positively electrified air drawn through salt water, has its electrification augmented.

§ 11. To test the effects of heat we drew air through combustion tubes of German glass about 180cm. long, and 2½cm. or 1½cm. bore, the heat being applied externally to about 120cm. of the length. We found that when the temperature was raised to nearly a dull red heat, air, whether positively or negatively electrified, lost little or nothing of its electrification by being drawn through the tube. When the temperature was raised to a dull red heat, and to a bright red, high enough to soften the glass, losses up to as much as four-fifths of the whole electrification were sometimes observed, but never complete diselectrification. The results, however, were very irregular. Non-electrified air never became sensibly electrified by being drawn through the hot glass tubes in our experiments, but it gained strong positive electrification when pieces of copper foil, and negative electrification when pieces of carbon, were placed in the tube, and when the temperature was sufficient to powerfully oxidise the copper or to burn away the charcoal.

§ 12. Through the kindness of Mr. E. Matthey, we have been able to experiment with a platinum tube one metre long and one millimetre bore. It was heated either by a

* "On the Electrification of Air," by Lord Kelvin and Magnus Maclean.

† The gasholder was 38cm. high and 81cm. in circumference. Ten strokes of the pump raised the water inside to a height of 8·1cm., so that the volume of air drawn through the receivers in the experiments was 428 cubic centimetres per stroke of the pump. This agrees with the measured effective volume of the two cylinders of the pump.

gas flame or an electric current. When the tube was cold, and non-electrified air drawn through it, we found no signs of electrification by our receiver and electrometer. But when the tube was made red or white hot, either by gas burners applied externally or by an electric current through the metal of the tube, the previous non-electrified air drawn through it was found to be electrified strongly positive. To get complete command of the temperature, we passed a measured electric current through 20cm. of the platinum tube. On increasing the current till the tube began to be at a scarcely visible dull red heat, we found but little electrification of the air. When the tube was a little warmer, so as to be quite visibly red hot, large electrification became manifest. Thus 60 strokes of the air-pump gave 45 scale divisions on the electrometer when the tube was dull red, and 395 scale divisions (seven volts) when it was a bright red (produced by a current of 36 amperes). With stronger currents, raising the tube to white-hot temperature, the electrification seemed to be considerably less.

THE MODERN APPLICATION OF ELECTRICITY TO TRACTION PURPOSES.*

BY PHILIP DAWSON.

The history of electric traction extends over a period of well-nigh half a century. As in the case of most similar developments of applied science, that history is largely a record of disappointment and failure of tests which promised much from a theoretical standpoint, but which wholly failed to demonstrate any probable practical value.

The self-contained car carrying a sufficient store of energy for a given period of operation was long the only idea of the inventor. The first radical departure was made by Siemens at the Paris Exhibition of 1878, where a stationary generating plant furnished power to the motors on the cars, the rails serving as the connecting medium. This, and the success achieved by the cable tramway, turned the tide of experimentation toward the evolution of a workable system of sub-service conductors. It was not, however, until 1884, when the overhead conductor was introduced, that any really efficient and practical solution of the problem seemed possible, and the succeeding four years were devoted to the elaboration of the many details connected therewith, and to the development of a type of apparatus which electrically and mechanically could withstand the excessive strains inseparable from tramway service.

It may be safely said that electric traction, as we to-day understand it, dates back no longer than 1888. That it should then have received, with all its imperfections, some measure of acceptance, is wholly due to the absolute necessity which existed in the United States for increased facilities of rapid transit. The horse tramway had failed to fill the demand—the introduction of cable could only be contemplated where a great passenger traffic was assured beyond question—the steam tramway was heartily disliked by one and all. One great company (the West End Street Railway of Boston), having an enormous interest in the development of suburban residential property, which could not be efficiently served by any accepted means of traction, took the bull by the horns and decided (and widely published) that it was prepared to investigate the question as to whether any new system of traction could meet its pressing needs and to adopt that one which could demonstrate success. The opportunity so offered, under conditions which assured experienced judges, a fair field, and a great reward for the successful competitor, was eagerly availed of. The modern history of electrical motive power begins with that competition. The result to the pioneer company can best be expressed in tabular form (Table I.).

We see that the decrease in the percentage of working expenses to gross receipts has varied almost directly in proportion to the introduction of electric plant. In 1888-9, before electricity was introduced, the percentage of expenses to earnings was 82 per cent. In 1890, as soon as the first outlying lines were electrically in operation, the percentage decreased to 77 per cent. In 1891, over one-fourth of the car mileage being electrical, the percentage is again decreased to 74·4 per cent. In 1892, with nearly one-half of the total mileage run by motor cars, the percentage drops to 70·8 per cent. In 1893, over three-fourths of the entire system having been electrically equipped, we find the ratio of expenses to earnings only 68 per cent., and the statistics of 1894 show the present operating expenses to be 66·44 per cent. of the gross receipts. This reduction has been made, notwithstanding the fact that the additional investment required for electrical plant and apparatus had to be provided for, and that such part of the former rolling-stock, buildings, horses, etc., as was rendered useless or disposed of at a loss, had to be written off. Moreover, the introduction of heavy motor cars, and of a service higher in speed, required that the permanent way should be reconstructed in many places, and much heavier metals employed. The results obtained in the whole State, of which Boston is the capital, are equally satisfactory (Table II.).

Table II.—Results obtained by the Introduction of Electrical Motive Power on the Street Railways of the State of Massachusetts (pop. 1890, 2,238,943).
(From the report of the Railway Commissioners of the State.)

	1888.	1894.
Total mileage of track	533·59	929
Mileage of track electrically equipped	nil	825
Total number of car miles run	23,244,767	36,722,978
Total number of passengers carried	134,478,319	220,464,099
Net earnings per car mile run, in pence	2·8	4·7
Percentage of operating expenses to gross income	81·07	69·5

These are the results obtained in but a single one of the United States, and that by no means the largest. It may incidentally be said, however, that no city in the Union is more English in type than Boston, and no State more closely resembles England than Massachusetts both from a social and commercial aspect.

It is interesting to note from the "Tramway Manual," 1894, that the total tramway mileage of Great Britain is 960 miles; the number of passengers carried in the year, 598,289,509; and the ratio of expenses to receipts 78·7 per cent.

cars and conduit-contained conductors were hopelessly out of the race. The trolley wire and wheel had demonstrated an overwhelming superiority. The new system of mechanical traction was accepted throughout America, and the subjoined Table III. shows with what amazing rapidity.

(To be continued.)

STORAGE BATTERIES.*

BY H. A. EARLE.

When I undertook to read a paper before this association I hoped that I might have been able to treat the subject in a more exhaustive manner. The time at my disposal has, however, been limited, and the subject is one of such magnitude, and the results under different conditions of test so numerous, that I have found it impossible to do more than give a general outline from a practical point of view. It is interesting to trace the history of storage battery manufacture, and by so doing each step in the advance up to the present time can best be considered.

The discovery of secondary currents dates back to 1801, when Gautherot found that silver or platinum wires, which had been used to decompose a saline solution, were capable of giving a reverse current of short duration. Ritter, in 1803, was, however, the first to make a secondary battery, in which he employed plates of gold separated by cloth or paper, the same being moistened with a saline solution. He experimented with various metals, including lead, but the secondary currents obtained were of short duration, and the batteries only of scientific interest. It appears at first sight strange that Ritter, when using lead, obtained no increased effects, this being the metal exclusively employed at this time. He, however, used salt water, and this formed chloride of lead, scarcely soluble, and a very bad conductor; on this account the current was very weak in comparison with that which would have been obtained if water acidulated with sulphuric acid had been used. Since that time many scientists have investigated the subject, and De la Rive in 1826 obtained secondary currents from platinum plates in a voltameter filled with water and sulphuric acid; and he closely approached the elements of our present storage battery when, among his many experiments, he used in a primary battery a platinum plate covered with a film of peroxide of lead and a zinc plate immersed in an acid solution. The first powerful storage battery was introduced in 1860, when Planté constructed cells composed of lead plates immersed in an acid solution of 1·068 specific gravity (10 per cent. acid); these were a success with the exception that the method employed for their formation—namely, frequent charges, discharges, reversal of charge, and periods of rest—was too long and expensive for practical purposes, several months being necessary to obtain a useful capacity.

The subsequent rapid development and improvements in electrical machinery and lamps created a real demand for a good storage battery, and turned the thoughts of many to the subject, and the next and one of the most important of subsequent improvements was that introduced by Faure in 1881—namely, of pasting a coating of lead oxide on the surface of the plates, which rendered them, after a comparatively short formation, ready for use. The Faure cell was never, however, as originally designed, a practical success, for though the active material was encased in a covering of flannel or felt, the pasted coating, being on upright surfaces and having insufficient adherence, came away within a period not sufficiently long to give economical results. Swan realised that the active material required a better mechanical support, and introduced a plate of grid form, the interstices serving to retain the material. This frame, combined with the Faure pasting, was the origin of the plate that has been largely used in this country and elsewhere. Up to the date of the expiration of the Swan and Faure patents the manufacture of pasted plates in this country was in the hands of one company and its licensees, and competition was thereby to a great extent absent. This is, however, more likely to have been an advantage than otherwise, for much has meanwhile been done to perfect and cheapen the production of the solid lead plates, and these are making such strides forward that it seems probable they will eventually outstrip and replace their pasted rivals. Solid plates have been made of various types, and some have been pasted to avoid the expense of formation, the paste in this case serving to give the required capacity till the action of charging and discharging gradually attacked the solid surface. Improved methods have, however, been discovered for effecting rapid formation at a reasonable cost, and although pasting is now open to all, in all probability there will be little extension of its use, unless means are devised for the better retention of the material. Another type which differs greatly from the solid lead plate, but which is not pasted, is the chloride plate. In this case the material to become active is a mixture of chloride of lead and chloride of zinc, which is cast into small tablets, these being framed by casting antimonious lead around them under high pressure. The subsequent elimination of the chlorine and zinc leaves a porous structure of pure lead of a crystalline nature, good conductivity, and with a large surface exposed to the electrolyte, the result being a large capacity for a given weight and for the space occupied.

The mere manufacture of an accumulator with lead and sulphuric acid is a simple matter, but when combined with the necessary requirements of low first cost for a given capacity and long life it presents more difficulties than is perhaps generally supposed. Omitting the question of cost, the chief points to be considered are the chemical action, the mechanical construction, and the proper treatment of the cell when made. In lead batteries the minimum weight is limited by the chemical requirements. The theoretical value of lead peroxide is 4·44 grammes per ampere-hour, or, roughly, 1lb. is the equivalent of 100 ampere-hours. Presuming that the positive and negative plates are identical, the value would be approximately 50 ampere-hours for 1lb. of peroxide and spongy lead. As a matter of fact, the highest-capacity plates yield only about seven ampere-hours per pound of positive and negative plates, or 16 ampere-hours per pound of peroxide and spongy lead, due to the facts that a conducting frame of considerable weight has to be employed, and to the impossibility in practical working of reducing the whole of the peroxide. To obtain the best results for a given weight, the frame must be reduced to a minimum consistent with the necessary strength and conductivity, and the distribution of the peroxide must be such as to admit of the perfect circulation of the electrolyte and its penetration throughout the mass. When the active material is retained in holes or interstices, due provision must be made for its expansion on oxidation, for the power exerted is so great that it will bend or burst a frame which holds it too tightly. Various methods have been adopted to prevent buckling, but it is still a source of trouble with perforated pasted plates. Solid grooved or ribbed plates, however, the grooves on which are filled with paste, are not subject to the same extent to this fault; solid plates, on which the active material is formed out of the substance of the plate itself, are practically free from it. In the chloride plate ample provision is made for this increase in volume by the elimination of the chlorine and zinc, which renders the structure porous and cellular.

Nothing is more interesting than the behaviour of cells under various conditions, and from the innumerable curves that can be plotted we can readily study the effects due to different rates of charge and discharge, to the penetration and strength of the electricity, and to the ratio of the positive and negative plates. From these and many other similar tests much useful information can be obtained for guidance both in manufacture and treatment. There is a given rate of charge for every type of cell which is most suitable, not only for its efficiency, but also for its durability. With some types a high rate is quite inadmissible, and a period of 10 hours is required; other types, however, are of such a construction that they may be fully charged in four hours without detriment. This variation is mainly due to the disposition of the active material, to its thickness, and to the method of its production—namely, whether it has been mechanically applied or electrolytically produced. Most of the effects of varying rates of charge can be ascertained from the resultant discharge, but discharge curves have nevertheless characteristics of their own which are to a great extent unconnected with the conditions of charge, and they depend upon the type of plate, strength of acid, the rate of discharge, and other influences.

A series of curves is exhibited (Fig. 1), and these give at a glance results obtained with plates of various manufacture; in every instance the weight of one positive and one negative has been taken. Knowledge of the ratio of weight of active material to frame is naturally necessary for the complete investigation of these curves, but in this case the weight of the plates themselves has only been taken into consideration, as it is merely intended to show results obtained from various types of plates at present manufactured. Curve A is taken from plates, the active material on which is of a very porous and cellular nature, of 5-16in. thick. It will be noticed that the capacity per pound of plate continues to rise up to the 12-hour rate, and that at that point is still slightly on the increase. This increase is, no doubt, partly due to the gradual penetration of the acid, and partly to the rapid sulphation of the surface at the higher rates. Curve B is that given by a positive plate, the active material on which is distributed in a thin layer over a very large surface, the negatives being the same as employed for Curve A. This plate gives less ampere-hours per pound of plate, owing to its possessing a heavy frame, but per pound of peroxide of lead its yield is greater; the active material in this plate is not formed out of the substance of the frame, but is entirely independent of it. A plate of this description, in which the whole face of the active material is directly exposed to the electrolyte, is capable of giving its maximum capacity at a comparatively high rate of

* Paper read at the meeting of the British Association at Ipswich.

Digitized by Google

discharge. A thin layer of peroxide spread over a large surface reduces the clogging of the surfaces to a minimum, and a free circulation of the electrolyte admits of fresh acid of the proper specific gravity being continually available. Curve C is obtained from a pasted plate suitable for slow rates of discharge, and from its rise in capacity at reduced rates we notice somewhat similar characteristics to that in Curve A. There is, however, a remarkable point of difference between Curves A and C, for the plates in each instance contain approximately 30 per cent by weight of active material; Curve A, therefore, gives us about double the ampere-hour yield per pound of active material over Curve C, and this is obtained by

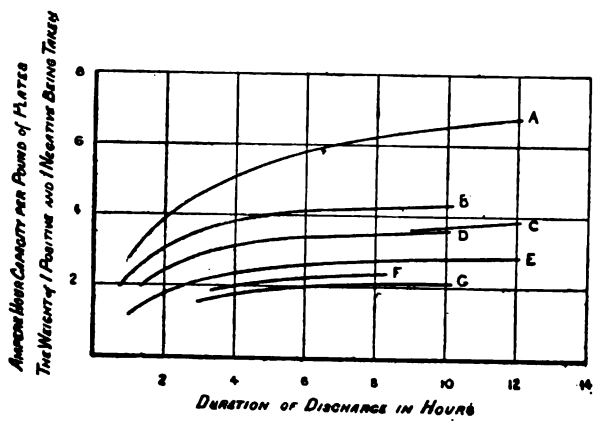

FIG. 1.

the cellular and porous structure of the material in the A-curve plate. Curve D is taken from plates cast with ribs on their surfaces, the active material being formed out of the substance of the plates themselves; the curve is very similar to B, but falls lower on the scale, this being caused by the weight of the positive plate, its thickness being considerable in order to give a reserve of metal, which in its turn is acted upon as the plate gradually disintegrates. Curve E is given by plates, the surfaces and interior being full of blowholes, which give a large exposed area; their weight for a given output is, however, large. Curve F is a pasted plate with a solid frame, which gives a poor return for its weight; in this curve we notice the rise in capacity at reduced rates due to pasted plates. Curve G gives the capabilities of very heavy plates which are pasted on their surfaces, the paste being intended merely to give the required capacity till its disintegration, by which time the frame itself has been sufficiently formed to do the work; the rapid flattening of this curve indicates that the layer of paste is thin. The curve of voltage of a discharging cell varies greatly, and is dependent upon the rate of discharge, the strength of acid, the distance of plates apart, its curve of internal resistance, and the treatment it has been subjected to beforehand, besides many other interesting conditions.

Fig. 2 demonstrates the effect of varying rates; these curves have all been obtained from cells of the same type, the acid having been approximately 1·210 specific gravity when the cell was fully charged. Discharges at varying rates are given—namely, 1, 2½, 3½, 5½, and 7½ hours—and though slightly different results would be obtained with other types of cells, they may be taken at a fair approximation for general reference.

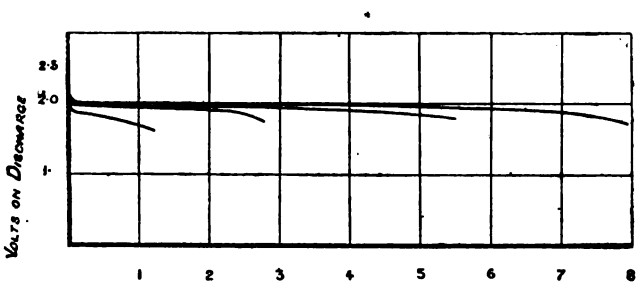

FIG. 2.

When considering the question of fall in volts on discharges at different rates, it will not be out of place to draw attention to conditions that are frequently given in specifications for storage batteries; in some instances a fall in volts not exceeding 8, 10, or 12 per cent. is allowed, and the rate in amperes and the time in hours for which the discharge is to be maintained are stated. This is in most instances unsatisfactory, for what are we to take as our starting point? The E.M.F. on open circuit immediately after complete charge is practically a fixed value, with a given type of cell and a known strength of acid. But the fall in the first few minutes varies greatly according to the rates of discharge, and at high rates it may fall as much as 10 per cent. in a few minutes, or even seconds, before a comparatively straight line has been reached and the cell is working at its normal voltage for the specified rate of discharge; this is quite clear by reference to Fig. 2. Another point to which our attention is drawn is the fall of voltage on open circuit after the completion of charge. A series of curves (Fig. 3) are exhibited showing the fall in voltage for a period of 21 hours, each curve being for a different strength of acid; it is therefore evident that if a given percentage of fall is allowed it will be most advantageous for the manufacturer, but not for the purchaser, to allow the battery to stand for a few hours in order that this useless high voltage be reduced. The best way to meet this point is, however, to take the first reading of voltage five or ten minutes after the discharge has commenced. In other specifications the voltage is fixed to a hundredth of a volt, and the cell must give the specified capacity above this limit. In many instances, and especially when high discharge rates are specified, the voltage given is much too high on the curve, and in some instances I have found it actually fall on a straight portion of the same, so that the time at which this point is passed raises an unpleasant difference of opinion between the buyer and the seller. This class of specification generally necessitates a very much larger battery than was intended, with corresponding increased cost; and should the manufacturer not have been exceedingly careful in preparing his estimate, he may find that the buyer is not satisfied with a good excess of ampere-hours, but will have his volts as well, even if this means 50 per cent. in ampere-hours in excess of what he thought he was ordering.

There are many ways in which a specification can be framed so that a battery of the exact size required is obtained, and there is no doubt that it is most satisfactory to all concerned if the exact capacity in ampere-hours is specified, and the final voltage of the complete battery at a given rate, the number of cells being omitted. Under these conditions, if the individual cells are discharged down to a low voltage, more cells would be required, but each additional cell on a 100-volt circuit adds 2 per cent. to their number, and correspondingly increases the

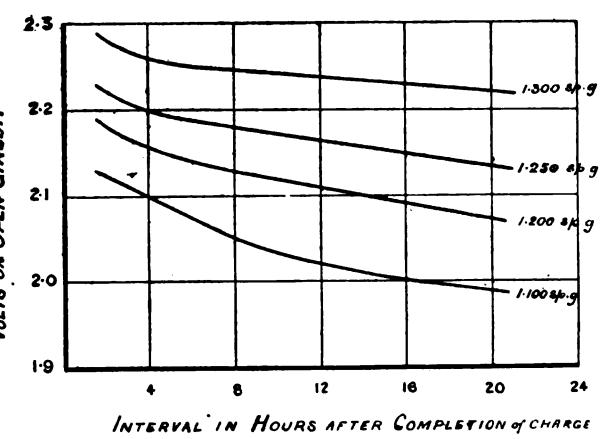

FIG. 3.

cost of a battery composed of cells of a given size. On the other hand, a low voltage per cell on discharge enables, up to a given limit, the number of plates per cell to be reduced, and the cost of cell as well. In a competitive tender the manufacturer would therefore work out the cheapest arrangement, and I find that this would not admit of the individual cells being discharged to too low a voltage, and that the purchaser would obtain exactly what he required at the lowest price. The actual number of regulator cells is of small moment to the user, and the additional number required when the individual cells are discharged down to a voltage of 1·8 in place of, say, 1·9, is only two in a 100-volt battery.

When tests are made to check the efficiency and capacity of a battery, we can place no reliance on the figures obtained from a single charge or discharge. As a rule, no two consecutive discharges from a cell are identical even when the same is discharged with the same current, and down to the same voltage, every discharge being greatly influenced by the previous treatment. Table A, given herewith, clearly demonstrates this. This table is in no way intended to be a guide as to what can be obtained in efficiency tests, but is merely to show the irregular nature of results obtained with slight variations in time and maximum voltage of charge; the rated capacity of the cell was 15 amperes for 10 hours, or 150 ampere-hours. Charge No. 1 we can omit, as this was given to complete the formation of the cell. Charge No. 2 was for a similar purpose. Charge No. 3 was continued, as were also charges 1 and 2, till the voltage had practically ceased to rise; a high voltage on charge gives a good return in ampere-hours on the discharge, but if a cell is forced to its maximum capacity we obtain a poor return in efficiency. Charge and discharge No. 4 are very similar to No. 3. Charge No. 5 was stopped when the E.M.F. had risen to 2·5 volts, and 30 per cent. less ampere-hours had

passed through the cell. Studying the figures up to the end of charge 5, it would have been practically impossible to assume what was going to happen on discharge No. 5; on taking this discharge we obtain 20 per cent. increase both in ampere-hour and watt-hour efficiency, and the very high percentage of the former—namely, 99·2 per cent.—points to the fact that peroxide, which had been previously inactive, was reduced. The first five discharges you will note were all taken down to 1·70 volts; this cell had never been used before, so we have its history up to the tenth discharge in the table—the strength of acid at end of charge was practically 1·300 specific in every instance. Charge No. 6 was only continued to 2·40 volts, but it required 2½ hours' longer charge to reach this voltage than it previously did on charge 5 to reach 2·5 volts, and this was without doubt due to the good service rendered on the last discharge. The remaining charges and discharges show that the highest efficiencies are obtained when the cell is not charged up to a high voltage, and if worked within reasonable limits 90 per cent. in ampere-hours and about 80 per cent. in watt-hours can be obtained with the cell in question, when in good order.

Usually, efficiency is not of great importance, for, presuming a central-station battery to give one-tenth of the total supply, a variation of even 10 per cent. in efficiency would only represent

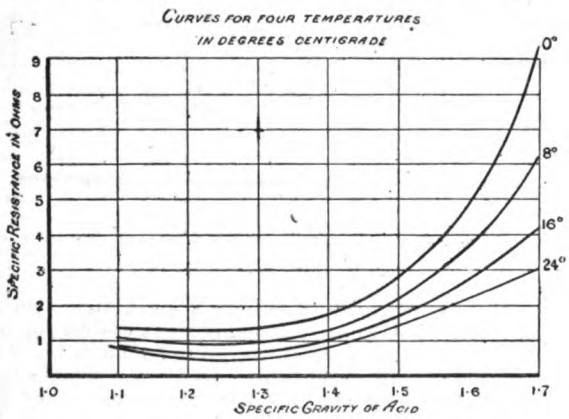

Fig. 4.

1 per cent. variation in the total output; but the time may come when batteries are so cheapened and perfected that they supply the whole demand of our station, and their efficiency will then be one of importance, and we may be confronted with specifications as strict as those now framed for dynamos.

The strength of acid solution to be used in a cell is an important point. In the first place, this greatly influences the voltage, as we have seen from Fig. 3; it has also a great effect upon the life. Besides this, in strong acid the plates sulphate more readily, and the sulphate is more difficult to reduce; it is therefore necessary to carry out most careful tests to ascertain what strength of acid should be used in each type of cell. The resistance of acid solutions of different strengths is also a most important consideration, and on Fig. 4 four curves are shown, giving its resistance at 0, 8, 16, and 24 degrees C. Taking 16deg. C. as a mean working temperature, it will be noted that acid of about 1·250 specific gravity has the least resistance, and it might be assumed, therefore, that this was the best strength to work at; but we must bear in mind that this strength does not give us the highest voltage, and, moreover, the gravity gradually falls as the cells discharges, and when working with this strength we have falling voltage on discharge, and at the same time increasing resistance of the electrolyte. No fixed law can be laid down, as each type of cell requires a given strength for best results.

Immediately upon commencing our research with a view to ascertain the proper strength of acid, we find that we are confronted with another problem of great interest, which is, that different strengths give us different capacities from our cell. Fig. 5 gives two most interesting and instructive curves taken from two cells of the chloride type—one with positive and negative plates of ·24 of an inch thick, Curve A, and one with positive and negative plates of ·4 of an inch thick, Curve B. Each cell was discharged at a rate equal to ·45 of an ampere per pound of plate. The rate per pound of active material is nearly the same for each cell, though perhaps slightly higher for the thinner plates. The rate of discharge per superficial area was therefore approximately 40 per cent. greater with the thick plates than with the thin. The curves give the yield in ampere-hours per pound of active material with different strengths of acid. Considering the thin-plate curve first, we find that with acid of 1·070 we do not obtain more than about 3 per cent. of the maximum

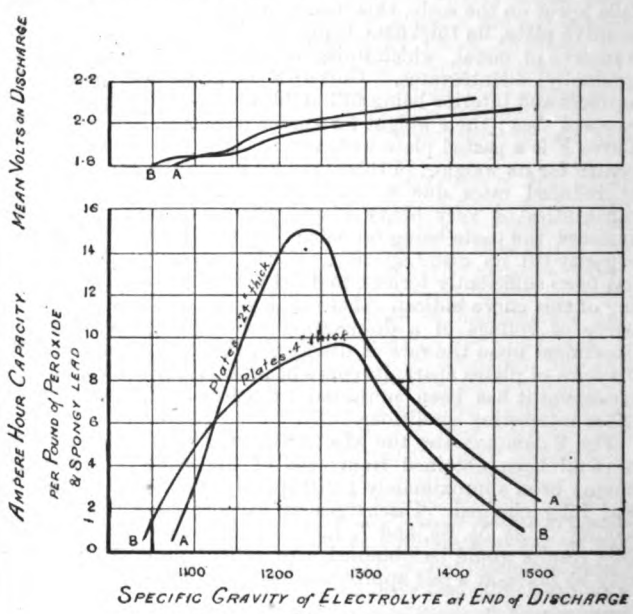

Fig. 5.

capacity; from this point to 1·230, at which point we obtain the maximum capacity, it rises very rapidly, each addition of 1 per cent. to the sulphuric acid present in the electrolyte giving an increase of about one ampere-hour capacity per pound of peroxide; from 1·230 to 1·500 it falls as rapidly almost as it rose, and at the latter figure we obtain only 16 per cent. of the maximum. Taking the thick-plate curve: at 1·040 specific gravity we obtain about 6 per cent. of the maximum capacity, and it rises till 1·270 is reached; it then falls rapidly, and at 1·500 the output is practically nil.

Considering these two curves, we note that the thin plates give as a maximum 15 amperes per pound of peroxide and spongy lead, or 30 ampere-hours per pound of peroxide alone, or about one-third of the theoretical value. The thick plates, on the other hand, give 10 ampere-hours per pound of peroxide and spongy lead, or 20 ampere-hours per pound of peroxide alone, or about one-fifth of the theoretical value.

The natural question is, why is this the case? also, why are the thick plates the best with very weak acid? and, who do they give such a much poorer return with acid of the strength usually employed? I consider that, up to the point at which the curves cross, that the better result obtained from the thick plates is due to the fact that, on completion of the charge in weak acid, the active material is saturated with strong acid, and the quantity contained in the same would be greater with the thick plates than with the thin, and they would therefore give

Digitized by Google

a better output with weak acid than the thin plates. Their increased thickness, however, is of no advantage with acid of the ordinary strength when out-capacity is chiefly dependent upon the penetration of the acid. If we study the portion of the thick-plate curve between 1·150 and 1·400 specific gravity and compare it with the thin-plate curve, we find that the capacity is practically reduced inversely as the thickness or weight of the plate and the rate of discharge per superficial area. Quite apart from the question of the proper thickness of the active material, we see at a glance that very different capacities are obtained with different strengths of acid. On the top of the same figure the mean volts during the discharge are given; these, it will be seen, rise steadily as the strength of the acid is increased. A striking feature is that the curves of voltage cross at the same point that the curves of capacity cross. Upon consideration, we come to the conclusion that this is what would be expected, as the rate in amperes on discharge was the same in every case, and an increase in ampere-hours per pound of material means a longer time to complete the discharge, and we see from Fig. 2 that the greater the length of the discharge the higher the mean voltage.

It is the manufacturer's business to make as good a cell as possible, but when it leaves his hands it is judged by the service it renders during its life. This depends to a very great extent upon the treatment it receives. In the first instance, purity of the electrolyte is essential. Brimstone acid should be used, as this is the least likely to contain foreign substances. If this is diluted on the spot, the water must be pure—preferably rain or, if possible, condensed water. With regard to the first charge of the battery, it is generally imperatively stated that this must commence immediately upon the acid being put into the cells. This is no doubt necessary with imperfectly-formed pasted plates, or with plates which have been for some time exposed to the air, as they would readily sulphate, and require considerable time to reduce, but positive plates which have been fully formed, and negatives in good condition, are very slightly affected.

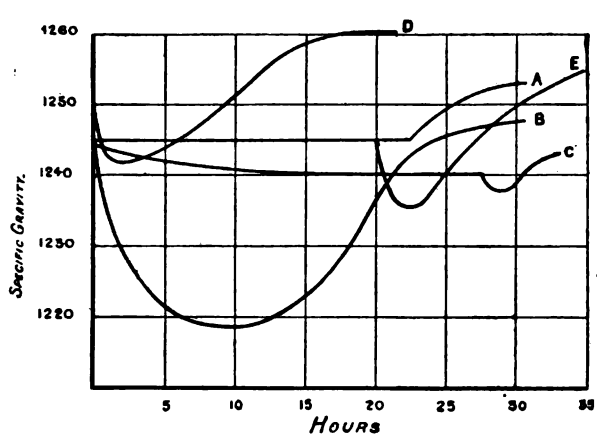

Fig. 6.

Fig. 6 gives five curves which I have prepared in order to show results obtained from plates in different conditions; some having been left standing in the acid while others were charged. Curve A shows the specific gravity of the acid in the cell in which the plates were allowed to stand for 22½ hours without being charged. During this period it remained absolutely constant, sulphation was therefore absent; the charge was then commenced and continued for eight hours: a rise in specific gravity took place, raising the electrolyte to a gravity above that at which it was put into the cell, which showed that sulphate was previously present in the plates. Curve B shows what happened in another identical cell—directly the charging current was started the gravity fell rapidly; this, I presume, is due to the formation of oxide of lead from the pure lead remaining in the active material, and this is sulphated before becoming peroxide of lead. The current throughout the charge was kept constant, and from the curve we see that practically the same number of ampere-hours were expended during the fall as during the rise; the specific gravity in this instance also rose slightly above its initial value. The plates in Curve C, which had been standing, sulphated slightly, and reproduced, on being charged, to a small extent a similar curve to B, and the plates (Curve D) which were charged at once give a very small fall but a considerable rise, showing that sulphate was present in the plates. Curve E is for plates which stood before being charged, and in this instance we notice that no sulphation took place, and that they gave a small fall and rise. My chief object in giving these curves is to demonstrate how very slight differences can give considerable variations.

To return again to the treatment of cells: the chief causes of destruction are too prolonged or excessive rates of discharge, insufficient charging, overcharging, long periods of rest on open circuit without charging, and allowing cells to remain after complete discharge for many hours before recharging. There is also another point worth mentioning. Frequently, through under-charge or over-discharge, the plates become heavily sulphated, the cells no longer give their proper output, and the specific gravity of the electrolyte falls considerably. Of course a prolonged charge will put this right, but frequently it is assumed that, as the specific gravity is low, the acid merely requires strengthening, and this is done with the best intentions; the fault is, however, aggravated, and the plates sulphate more heavily than before. I found on one occasion that acid had been periodically added, and the specific gravity rigidly maintained at 1·200, the charge being always stopped when this strength was reached. The cells were naturally working very badly. A prolonged charge was accordingly given, and this raised the strength of the electrolyte as high as 1·450 in some cells, which was a clear indication of what had been done. We find, therefore, that a multitude of causes influence the working and life of storage batteries, and that many of these can be varied at will; the problem, therefore, is to so combine all useful effects that we produce the best possible article with due consideration to low cost.

It would be a natural question to ask, What do you consider the best possible article? and this is easily answered. In a secondary battery we have lead, sulphuric acid solution, and the resultant compounds, and nothing else. The ideal cell is one that is indestructible, and this being given, the first cost and weight, if kept within reasonable limits, are of little moment. At the present moment the life of a cell is its value, and all types are constructed with the knowledge of certain death; and in most types this lingering death is provided for, for we find at the bottom of the boxes a sufficient space to act as a receptacle for the deposit from the disintegrating plates. In other types, where the active material is held permanently in position, disintegration still goes on, with consequent loss of contact. Now, this disintegration is what we have to stop. The deposited disintegrated material is as good as ever, for nothing is wasted; and provided it were held in perpetual, firm, and good electrical contact with the frame in such a manner that the free circulation and penetration of the acid were not hindered, and the internal resistance were not unduly increased, we should have produced an ideal and indestructible cell.

I have brought to your notice only a very few of the many interesting features in connection with secondary batteries, and these only in a most superficial manner. I have, however, endeavoured to give a general outline of results obtained in practice, and have not entered into a discussion upon other more serious questions. Many conjectures arise in one's mind when considering the causes of different effects, and each point requires much time and study in order that a fixed law may be deduced from the results obtained; and again the results of tests are often so conflicting, and depend so much upon very small differences of condition, that it is by no means an easy matter to arrive at the truth.

THE HERMITE PROCESS OF DEODORISING SEWAGE.*

BY J NAPIER, F.C.S., F.I.C., ETC., BOROUGH AND COUNTY ANALYST.

The treatment of sewage for the purpose of preventing putrefaction is a subject which has occupied the minds of chemical and sanitary engineers for many years, and numerous methods of dealing with it have been devised and brought before this and other societies, each claiming to perform its work in a more perfect manner than its predecessor. Those methods, with only one or two exceptions, treat the sewage at a point between the last inlet into the main sewer and the outfall, usually at the outfall, and as far away from the town as it is possible to put it. Those systems of dealing with sewage at the outfall do not give the town from whence it came any sanitary benefit. They do not prevent sewer gas accumulating in the sewers and escaping into the air from manholes or ventilating shafts and becoming an annoyance and nuisance to the inhabitants. The objects of those systems of treating sewage, then, is to purify the sewage sufficiently to prevent the pollution of a waterway or river, and without in any way being of the slightest benefit to the health of the town. With the Hermite process the sewage is treated at the other end of the sewers—*i.e.*, at the beginning—deodorised there, so that flowing through a town the sewers give off no offensive smells, and the putrefactive changes which take place in sewage have been arrested. With this system, then, there is no need for ventilating shafts, and if the manholes are perforated there is no offensive smell given off; on the contrary, there is a faint chlorous or bleach smell, which is much more acceptable to the nose than sewer gas. The principle of this process is passing a current of electricity through sea-water, or,

* Paper read at the meeting of the British Association at Ipswich

Digitized by Google

if sea-water is not handy a solution of magnesium and sodium chlorides; a portion of these chlorides is converted into hypochlorite, a substance which disinfects, deodorises, and bleaches similar to the active ingredient of bleaching powder — calcium hypochlorite. The change from chloride to hypochlorite takes place almost entirely with the magnesium salt-yielding magnesium hypochlorite ($MgCl_2O_2$). It is found, however, that in the electrolysers and tanks a white deposit takes place, consisting of magnesium oxide combined with water—viz., magnesium hydrate—showing that the magnesium hypochlorite has decomposed, forming magnesic hydrate, which precipitates, leaving hypochlorous acid in solution. The action may take place as follows: $MgCl_2O_2 + 2H_2O = MgH_2O_2 + 2HClO$. This is called the Hermite solution. The amount of oxidising power is expressed by the quantity of available chlorine in grammes per litre—the usual working strengths being from five to one gramme per litre of solution. When sewage is mixed with about 5 per cent. of the gum solution, the offensive smell is instantaneously destroyed and the decomposition arrested for about six days, long enough under ordinary circumstances for the sewage to be well out to sea. I have not attempted to give a description of the electrolysers and their working: it would only be taking up valuable time. Those who are interested and will visit the installation in Constantine-road, will see the plant at work, and have all details explained. This electrolysed, or Hermite, solution has been subjected to many experiments, and numerous criticisms have been made upon it as to its power of rendering sewage sterile—as, for instance, the *Lancet* Commission, who report favourably on the system from experiments made at Worthing; also by Sir Henry Roscoe and Mr. J. Lunt, B.Sc., the results of which were read before the Society of Chemical Industry and described in that society's *Journal* in March last. Sir Henry found that a ·8 gramme solution practically sterilised the liquid portion of sewage, when used in sufficient quantity, and that the solid matters were unaffected. Well, a solution which will thus practically sterilise liquid sewage must, I think, be of great value, and when used in effective quantity tend to benefit any locality by preventing those contagious diseases which are usually developed from sewer gases. Although chemical and sanitary engineers have had this aim—*i.e.*, to completely sterilise sewage—in view, this point has not been attained on the large scale by any of the at present known systems. Hermite solution, however, does the next best thing, for in larger proportions it sterilises the liquid portion, and even in small quantities completely deodorises. This is confirmed by Sir Henry Roscoe's eleventh conclusion—viz., "the Hermite fluid even of ·25 strength acts as an excellent deodoriser." This is the point taken up by the Ipswich Corporation. They say, if we can have the sewage deodorised and its decomposition arrested for from three to six days the sewage will be well out to sea, and the nuisances of offensive smells in the town will be entirely done away with. Sir Henry also made experiments as to the stability of the electrolysed solution, and he found that a ·5-gramme solution lost 90 per cent. of its strength in 24 hours, a ·75-gramme solution being more stable, losing 34 per cent., and a 1-gramme solution 10 per cent. in the same time. This is very interesting and important, but as regards the working of the system in Ipswich, it is not necessary to take this into consideration, because the moment the electrolysed solution is made it is carried direct into the sewer within two minutes after its production. We have in Ipswich been electrolysing sea-water for three months and treating the sewage. The Sewage Committee directed me to report on its working, so I made daily tests and inspections for about two months. The strength of solution varied from half a gramme to one gramme, according to the flow of sea-water through the electrolysers, the quantity of available chlorine made being fairly constant, and the average being 1·04 gramme per ampere-hour. As to the effects of this solution on the sewage I have no figures to give you, but can give a general idea of its deodorising powers. I shall first draw your attention to a plan of the town of Ipswich, its situation with regard to the rivers, and the course of the sewage to the outfall. We have two rivers—viz., the Gipping, a canal which extends to and is navigable as far as Stowmarket, about 10 miles inland. The last or bottom lock is situated near Handford Bridge. Below this point the river is tidal, and is called the Orwell, which for beauty at high water is not to be excelled even by the Clyde or Rhine. In close proximity to the town we have the dock, covering about 33 acres, along each side of which the principal merchants of the town have their works or premises for shipment. The Gipping has an arm which leads from the locks to where there was once an oil-mill (now the steam laundry) driven by a waterwheel, and from this there was a waterway through the town as far as Fison's Mills at Stoke Bridge. When Ipswich was sewered, about 16 or 17 years ago, according to the suggestions of Mr. P. Bruff, and carried out by our present borough surveyor (Mr. E. Buckham), the main or intercepting sewer was laid in this waterway, from Portman-road, as far as it went, and continues to the outfall. The difficulties in the way of sewering and treating sewage in Ipswich may be explained in Mr. Buckham's own words: "To dispose of the sewage of Ipswich, either by irrigation or by intermittent filtration, would be attended with considerable expense. The town is divided by the River Orwell, and, as is frequently the case with towns so situated, the longitudinal falls are very slight, while the lateral falls are very great. The fall from the one end of the sewer to the other is only 8ft., so the flow is not very rapid, whilst, taking a section of the town laterally, there is plenty of fall, and, in consequence, a rapid current into the main sewer. On this account the experiments with the electrolysed solution were made on the main sewer, and at present the solution is running in the sewer at Handford-road in close proximity to the beginning of the main sewer. The result is complete deodorisation of the sewage throughout a long length of the sewer. For a distance of 700 yards free chlorine can be instantly detected by test papers, and for a distance of 1,760 yards the chlorous smell is perceptible, although insufficient to have any action on the test paper. Not only does the main sewer receive the arterials, but it receives the drainage of several slaughter-houses and breweries containing much organic matter. Below the point indicated (Church-street, St. Clement's) there is such a great increase in the quantity of sewage that the results were doubtful. On several occasions, however, samples taken from the outfall were without smell and kept two days, and in one instance it kept four days. If the amount of electrolysed solution, or its strength, could have been increased, the sewage at the outfall would certainly have been completely deodorised, if not sterilised. This is a point which I hope the Sewage Committee will aim at, and when putting the plant permanently into the new buildings that they will have sufficient electrolysers and power to produce enough fluid to deodorise all the sewage of Ipswich and have some to spare for flushing or washing infected areas. I noticed in some of my early morning inspections, when the flow of sewage was at its minimum, that the deposit in the sewer was bleached nearly white by the action of the electrolysed solution. This process has not been going long enough to allow me to obtain any statistics as to the health of the borough or the death-rate, compared with previous years and with other towns; but this I am sure of, that where the sewage has been treated no complaints have been received as to offensive smells. I am confident that any town that adopts this process, which will boldly erect plant to produce more than enough of the electrolysed solution, will be spending money well, and in time will feel the benefit by increased health of the inhabitants, and also by having a lower death-rate. This is what I have suggested Ipswich should do, so that in a year or two, when we are able to make comparisons, we will find a reduction in the death-rate. Such a result will make the process cheap at any price."

COMPANIES' MEETINGS AND REPORTS.

ROCKHAMPTON (QUEENSLAND) GAS AND COKE COMPANY, LIMITED.

In their report for the half-year ended June 30 last the directors state that the electrical operations of the Company show a profit of £303, 13s. 9d., from which has been paid £300 interest upon the whole of the Company's debentures, leaving an unappropriated balance of £3. 13s 9d. to the credit of the profit and loss account of this section of the Company's business. During the half-year some additions, improvements, etc., have been made to the gas plant and the electric lighting plant and buildings. Reference was made in their last report to the engagement in London of a new electrical engineer. The candidate selected from a very large number of applicants by the Company's agents, after careful scrutiny into his antecedents and past professional experience, was Mr. E. F. J. Hewlett, M.I.E.E, who has been connected for some years with large electrical firms in England.

BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.

Directors: J. B. Braithwaite, jun., Esq. (of Messrs. Foster and Braithwaite), chairman; Arthur Ayres, Esq., M.I.C.E.; Aymor H. Sanderson, Esq; Colonel Frederick George Steuart; B. H Van Tromp, Esq; Edward Woods, Esq. (past-president of Institution of Civil Engineers). Joint managers: John S. Raworth, M.I.C E.; R. Percy Sellon, M.I.E.E.

Sixth annual report to be presented to the shareholders at the general meeting of the Company to be held at Cannon-street Hotel, London, E C., on September 23, 1895, at 12 noon:

The profit and loss account shows a gross profit of £37,858. 4s. 5d., after providing for bad and doubtful debts to the amount of £2,205 17s. 9d., and writing down the value of shares and debentures in other companies, as shown in the balance-sheet. After deducting from the gross profit, general charges, maintenance of buildings, plant and patents, staff bonuses under the Company's profit-sharing scheme, and interest on debenture stock, there remains a net balance of profit, after including the amount brought forward from last year, of £11,329. 12s. 8d. An interim dividend at the rate of 6 per cent. upon the preference shares, and at the rate of 5 per cent. upon the ordinary shares, has been already paid for the half-year ended December 31, 1894, amounting to £12,150. It will be seen that the net profit for the year, exclusive of the amount brought forward, is £7,541. 3s 8d. The preference shareholders have already received £5 400 of this amount by way of interim dividend as above, and they will be entitled to receive the balance of £2,141. 3s. 8d. before the ordinary shareholders receive further dividends. Whilst the directors regret this result of the year's operations, which shows a decrease of net profit as compared with last year of £19,739. 8s. 5d , they think it right to state that it is solely due to loss incurred during the second half of the Company's financial year in connection with the contract which the Company is carrying out for the City of London Electric Lighting Company, Limited, and arises out of differences between the two companies as to the obligations involved under the contract. The directors are glad to be able to state that these differences are now at an end, and work under the contract is being again proceeded with. During the year the sum of £2,646. 1s. 9d has been expended on capital account, upon extensions of buildings and plant at the Loughborough works, and new patents taken over by the Company. The Austrian business of the Company, carried on from the Vienna factory of Messrs. Kremenezky, Mayer, and Co., has yielded improved results during the past year, and is now established upon a thoroughly profitable basis. The Australasian branch, having its headquarters at Sydney, New South Wales, has also shown a satisfactory profit for the year ended April 30 last, and with the improving commercial prospects in the colonies, correspondingly favourable results from this branch of the Company's business may fairly be expected. The contract and installation department has been fully employed during the 12 months under review, and central electricity supply stations for the municipalities of Leicester and Worcester, and for the Dover Electricity Supply Company, have been equipped with the Company's electrical plant and opened during the year. The Loughborough works are at present fully engaged on orders, and sufficient work is in hand and in prospect to maintain them so for some time to come. In the electrical shops plant is in course of manufacture for the equipment of electricity supply stations in St. Luke's, Middlesex, the Wandsworth district, and for the lighting of Valetta and the Government works at Malta, for which an order has recently been received. The rolling-stock and car departments are engaged upon the construction of locomotives for the Beira Railway, of cars for the Rouen Electric Tramways Company, and other orders. The directors are pleased to report that they have made arrangements for the manufacture of a new high-speed enclosed engine of a novel and simple construction, the invention of the Company's joint manager and chief engineer, Mr. J. S. Raworth. There is at the present time a large demand for engines of this class. The new engine has been submitted to Prof. W. Cawthorne Unwin, F.R.S., and to Mr. W. H. Maw, M.I.M.E, copies of whose reports are enclosed. The bonus profit-sharing scheme introduced among the Company's staff and workmen two years ago is giving general satisfaction among the employés, and the directors are satisfied that the scheme is working well In order to provide capital to meet the large expansion of the Company's business which has taken place since the last issue of capital early in 1893, the directors have decided to make an issue of second 4½ per cent. debenture stock to the amount of £105,000, which will be allotted at par to the holders of preference and ordinary shares. The entire interest charge on the Company's debenture stock, including the £105,000 now to be issued, will then stand at £10,350 per annum. The average annual net profit (including debenture interest) for the past six years, since the Company was formed in 1889, amounts to £25,337. The stock will therefore be amply secured. The increase in the extent and volume of the Company's business, especially during the past few years, is largely due to the development in this country of municipal and private electricity supply from central stations, of which business the Company has been successful in securing a substantial share. The manufacture of steam-engines for electrical engineering purposes has also been undertaken during that period, and upwards of 35 000 h.p. have been sold. The Company are also giving close attention to electric traction and electric elevator work, in both of which directions an important development appears to be imminent. Mr. Edward Woods and Mr. A. Ayres are the directors who retire by rotation, and, being eligible, offer themselves for re-election. The auditors, Messrs. Cooper Bros. and Co., also offer themselves for re-election.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ashton-under-Lyne.—Tenders are invited for the supply of an electric light installation. Apply to Wagstaffe's Steam Preserve Works, Hurst Brook, Ashton-under-Lyne.

Tongres.—The Municipal Authorities of Tongres (Belgium) invite tenders by October 12, 1895, for the concession for the installation and working of the electric light in the town.

Alexandria.—The Municipal Authorities of Alexandria, Egypt, invite applications by October 1, 1895, for the concession of the tramway lines from St. Catherine Place, through the outer boulevards, to the projected abattoirs at Mex, with a branch line. Security £E1,000.

Southmolton (N. Devon).—The Southmolton Shirt and Collar Manufacturing Company, Limited, invite tenders for wiring the factory buildings for the electric light and ironing, including all the electric generating plant. The company find the power. Particulars of the Secretary, Southmolton, N. Devon.

Leeds.—Tenders are wanted for providing and fixing several new lightning conductors, and for repairing others, upon and at the workhouse premises in Beckett-street for the Guardians. Specifications can be obtained on application at the offices Tenders to be sent to Mr. John King, clerk, Union Offices, East-parade, Leeds, by 24th inst.

Braila.—The Municipal Authorities of Braila, Roumania, invite tenders by October 2 for the construction and working of a system of electric tramways in the city. Provisional security, 10,000f. This contract was originally fixed for July 29. Tenders are further invited by the Municipal Authorities of Braila for the lighting of the city by electricity or by electricity and gas. Provisional security 10,000f.

Chepping Wycombe (Bucks.).—The Urban Sanitary Authority for this borough are prepared to receive tenders from public companies for working the electric order obtained by them within the borough for a term of years and upon approved conditions. Tenders are to be delivered by noon on October 14 next, at the office of the town clerk, High Wycombe, where a copy of the electric order may be seen and further particulars obtained. The Authority do not bind themselves to accept any tender.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

Blackburn.—The Corporation of Blackburn invite tenders for the following: Contract No. 1.—High-tension concentric cables, low-tension triple concentric cables, cast-iron pipes, junction-boxes, drawing in boxes, service-boxes, etc. Specification, conditions of contract, and forms of tender may be obtained at the offices of Mr. E. M. Lacey, 10, Delahay-street, Westminster, on and after September 23, on payment of £1. 1s., which will be returned on receipt of a bona fide tender. Tenders, sealed and endorsed "Electricity Extensions," must be delivered at the Town Hall, Blackburn, on or before October 5.

Dewsbury.—The Corporation invite tenders for wiring the Public Baths and Library. Forms of tender and copies of specification may be obtained from the borough electrical engineer, Electricity Offices, Bradford-road, Dewsbury, on payment of £1. 1s, which will be returned on receipt of a bona fide tender, together with the specification. Plans may be seen at the office of the borough electrical engineer, Bradford-road, Dewsbury, from whom any further information can be obtained. Sealed tenders must be sent to Mr. E Mawdesley, town clerk, endorsed "Electric Lighting, Public Baths and Library," not later than 12 noon on Saturday, the 21st inst.

Dundalk.—The Dundalk Town Commissioners invite tenders for erection of an electric lighting installation for the purpose of lighting the town by electricity on or about July 1, 1896, reserving to themselves the right of taking over the plant at the end of a term of years—this term to be stated in the tenders. The successful contractor to have the right of supplying private consumers, while the Commissioners will pay a fixed sum yearly for the town lighting—this sum to be stated in the tender also. The Commissioners have obtained a license from the Board of Trade for supplying electric lighting. Tenders will be received by Mr. Edward Farrar, town clerk, Town Hall, Dundalk, up to October 7.

Eccles.—The Corporation invite tenders for the supply and erection complete of the following apparatus and plant: Lancashire boilers; alternating-current dynamos and engines; cables, street boxes, etc.; transformers. Tenders may be sent in for any section or for the whole of the sections, but not for part of a section only. Plans of the district can be seen and copy of the general conditions, specification, and form of tender can be obtained on deposit of £5. 5s., which will be returned on receipt of a bona fide tender. at the town clerk's offices, Eccles, or at the offices of the consulting engineer, Mr. S. V. Clirehugh, Temple-chambers, Brazenose street, Manchester. Sealed tenders, which must be on the prescribed form, endorsed "Tender for Electric Lighting," to be delivered to Mr. Geo. Wm. Bailey, town clerk, Town Hall, Eccles, by 12 noon on 30th inst.

Belfast.—Tenders are invited for the supply and erection of two direct-coupled steam-engines and dynamos, battery of accumulators, main switchboard, and installation of about 232 incandescent lamps, complete, for the lighting of Belfast Lunatic Asylum, for the Commissioners for the Control of Lunatic Asylums. Tenders should be sent in a sealed envelope, endorsed outside "Tender for Works for Lighting Purdysburn Asylum," and addressed to the secretary, Board of Control, Custom House, Dublin, and accompanied by a separate sealed envelope, similarly addressed and endorsed, containing the detailed estimate. Forms of tender will be issued on application to the office of the Board of Control of Lunatic Asylums, Custom House, Dublin, on deposit of £1. which will be returned to all persons who have sent in bona fide tenders. Plans and specification can be seen at the office of Mr. O A. H. M'Cowen, Chapel-lane, Belfast. Tenders by 10 a.m. on 28th inst.

Harrogate.—The Corporation of Harrogate invite tenders for wiring the new Montpellier Baths for electric lighting. Specifications and full particulars may be obtained of Messrs. Baggallay and Bristowe, architects, 66, Conduit-street, London, W., on payment of £1. 1s., returnable on receipt of bona fide tender. Sealed tenders, endorsed "Tender for Wiring New Baths," are to be sent to the town clerk, Municipal Offices, Harrogate, by September 30. The Electric Lighting Committee desire tenders for the supply and erection of the following plant: (Section A) Lancashire boilers, economiser, feed pumps, and accessories; (B) steam alternators, condensers, fittings, etc., steam, exhaust, feed, and sundry pipes, valves, etc.; (C) switchboard and instruments; (F) transformers and accessories; (G) meters; (H) overhead travelling cranes. Tenderers are at liberty to tender for any section or sections, or for the whole of the sections, but not for a portion of a section. Specifications may be obtained on application to the borough surveyor, Municipal Offices, Harrogate, on payment of £2. 2s., which sum will be returned on receipt of a bona fide tender. Tenders, sealed and endorsed "Tender for Electric Lighting," must be addressed to the town clerk, Municipal Offices, Harrogate, and delivered by September 30.

RESULTS OF TENDERS.

Tunbridge Wells.—The contract for lighting by electricity St. Mark's Church, Tunbridge Wells, has been awarded to Messrs. Gilbert and Co, of 35, High-street, Kensington.

Taunton.—The tender of the British Thomson-Houston Company, Limited, at £1,058, has been accepted for supplying an alternator and engine, for the Electric Lighting Committee of the Town Council.

London, W.C.—The Guardians of St. Giles and Bloomsbury have accepted the tender of the Brush Electrical Engineering Company, 49, Queen Victoria-street, E.C., for carrying out the work required in supplying and fixing wires, cables, and fittings for the installation of the electric light at the Board-room and offices, 57, Broad-street, W.C.

Bedford.—The following tenders were received for the supply of vulcanised rubber cables, for the Urban Sanitary Authority:

Henley's Telegraph Works Company, London (accepted)	£1,797	13	3
Telegraph Manufacturing Company, Helsby	2,582	6	8
India Rubber, Gutta Percha, etc., Company, Silvertown	2,077	16	4
W. T. Glover and Co., Salford	2.131	7	1
Siemens Bros. and Co., London	2,158	12	11

Leyton.—At a special meeting of the Leyton District Council the following tenders for wiring the new public offices and technical institute were opened:

	Public offices.			Technical institute.		
Drake and Gorham	£573	14	2	£382	7	4
Paterson and Cooper	500	10	3	359	7	8
Sharp and Kent	630	15	4	402	5	2
Crompton and Co.	660	13	5	543	2	1
Strode and Co.	493	3	3	323	13	2
Joel and Co.	510	13	5	324	7	3
Wigston Electrical Engineering Company	457	14	7	303	18	6
Brush Electrical Engineering Company	472	5	11	306	15	9
Spagnoletti and Crookes	475	8	0	315	12	0

The Chairman said that Prof. Robinson was of opinion that the firms were equally good. The tenders were referred to the General Purposes Committee for consideration.

Yarmouth.—The Town Council have accepted the tender of Messrs. Bateman for coal at 14s. 6d. per ton; of the British Insu-

Digitized by Google

lated Wire Company, at £1,031. 1s., for a new cable, including laying and jointing; and that of Messrs. Crompton for transformers—these being the lowest received.

Portsmouth.—The following tenders have been received by the Corporation for the wiring and lighting by electricity of the police stations at Buckland, Southsea, Portsmouth, and Portsea:

Newton and Co., London (accepted)	£27	10	0
S. Grossmith, Portsea	42	15	0
J. Southey, Southsea	44	19	3
A H. Wood, London	42	0	0
W. H. Sabine, Southsea	39	15	0
J. R. Penning, Southsea	39	5	0
Bowerman Bros, Southsea	41	7	6

BUSINESS NOTES.

Bristol.—Satisfactory trial runs have been made with the new electric tramcars.

Middlesbrough.—The Town Council have resolved to defer the question of introducing the electric light.

Bootle (Lancs.).—The Town Council have obtained a provisional order to carry out the system of lighting by electricity, and are formulating a scheme.

Scottish House-to-House Electricity Company, Limited.—The transfer books of this Company will be closed from September 19 to September 30, both days inclusive.

Royal Electric Company of Montreal.—The Bank of Montreal will pay, on and after the 1st prox., the coupons then due of the 4½ per cent. debenture loan for £120,000.

East Grinstead (Sussex).—The Guardians have ordered a letter from Messrs. Petit and Hards, asking to be allowed to give an estimate for the electric lighting at the workhouse, to be placed on the table.

Brighton.—A prolonged discussion took place at the last Town Council meeting with reference to the electric railway, delay having been caused in the construction of the road by a deviation in the plan.

Brussels.—The formation of the Compagnie des Tramways de Saint-Quentin is announced from Brussels. The capital is 2,000,000f. in 100f. shares. M. Victor Popp is at the head of the undertaking.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 15th inst. amounted to £1,278, as compared with £1,084 in the corresponding week of last year, being an increase of £194.

Sheffield.—The City Council have found that they must borrow £40,600 to complete their new town hall and provide it with fittings, including electric light fittings and some building work. This is in addition to £90,000 already borrowed.

Southend.—A project for lighting the Western Esplanade with incandescent gas lamps has been referred back by the Town Council until the committee has reported upon the desirability or otherwise of utilising electricity in the borough

Caddy and Co.—We have received a copy of the catalogue of the rocking, stationary, and forced-draught furnaces, fitted with tubular firebars to suit all classes of coal, made by Messrs. Caddy and Co., Limited, of Daybrook Ironworks, Notts.

Wolverhampton.—The Town Council have received a letter from the Local Government Board stating that an inspector would hold an enquiry respecting the application of the Corporation to borrow another £5,000 for extending the electric lighting works.

Llanelly.—Messrs. J. C. Howell and Co., electrical engineers, have applied to the Urban Council, asking if they were prepared to transfer to them their powers for lighting the town by electricity, and if so, upon what terms. The matter has been deferred.

Wakefield.—The tenders for the electricity supply works have been opened by the Electric Lighting Committee of the Town Council, and are now being analysed by Mr Robert Hammond, M.I.E E, of Ormond House, Great Trinity-lane, E.C. They number 49.

Aberdeen.—We are in receipt of a letter from the British Insulated Wire Company stating that the whole of the extensions at Aberdeen this year requiring cables have been carried out by them, and that our note in the Aberdeen number *re* extension of mains hence needs correction.

Earlston (Berwick).—Negotiations are still going on with a view to the introduction of the electric light in Earlston. The proposal has been very warmly received by the inhabitants generally, and there is a marked preference for the electric light over the proposal to purchase the gasworks.

City and South London Railway.—The returns for the week ended September 15 were £808, compared with £826 for the corresponding period of 1894, being a decrease of £18. The total receipts for the half-year 1895 are £9,316, compared with £9,402 for the corresponding period of 1894, being a decrease of £86.

Direct Spanish Telegraph Company.—The Board of the Direct Spanish Telegraph Company have decided to pay, in addition to the dividend at the rate of 10 per cent. per annum on the preference shares, an interim dividend at the rate of 4 per cent., free of income tax, on the ordinary shares, both for the half-year ending June 30.

Appointment Vacant.—An assistant demonstrator in the department of electrical engineering at the City and Guilds Technical College, Finsbury, is required. One having experience of alternate-current work preferred. Salary to commence at £80 per annum. Apply to the Principal, City and Guilds Technical College, Finsbury.

Whitehaven.—The Town Council have received several informal applications for supplies of the electric current in Duke-street and elsewhere, and the surveyor has submitted alternative schemes for laying a cable in Duke-street, and has been instructed to prepare a statement showing the available electric lighting capital and the estimated outlay against it.

Worksop.—Complaints were made at the last Urban Council meeting of the inefficiency of the gas supply, but several members were in favour of letting the gas question alone on the ground that in all probability the town would eventually adopt the electric system of lighting, and that a company was about to be formed for the purpose of introducing the electric light to Worksop.

Swansea.—The scheme for lighting the main streets by electricity, and at the same time using the plant for the purpose of destroying the town refuse, is now complete. The Corporation Committee have finally considered the report, which will be presented to the Corporation. The work, which is to be carried out under the superintendence of Mr. Manville, will cost about £50,000.

Ashton-under-Lyne.—The question of providing an electric installation for the borough is under consideration. Alderman Andrew said, at the last Town Council meeting, that the users of the light ought to bear the burden, and the general ratepayers ought not to be saddled with any part of the cost except in regard to public purposes like street-lighting and the illumination of the Town Hall.

Kettering.—The Urban Council have appointed a committee of eight members to take into consideration the supply of electricity for lighting and other purposes, and to call expert evidence if necessary, the latter not to exceed a cost of £30. Speaking in support of the motion, Mr. Gorman said he had been given to understand that if the Council did not take the question up a company would be formed in the town.

Queenstown.—The Town Commissioners have received several applications to tender for lighting the town by electricity. The Chairman said at the last meeting that it was well that the public should know that the Commissioners were strong in their determination to have the town lighted by electricity, but with a clause inserted in the agreement that after a certain number of years the plant would become the property of the town.

Aberdeen.—The Education Committee of the Governors of Gordon's College have received a letter from Mr. E. T. Ruthven Murray, formerly electrical engineer to the Corporation of Aberdeen, with reference to the electric lighting of the college. Mr. Murray explained that, after full consideration, he thought the amount mentioned in a previous letter quite sufficient to cover all outlays in connection with the introduction of the lighting. It has been agreed to give Mr. Murray an honorarium of 20 guineas for his services as engineer on the occasion of the installation.

South Staffordshire Tramways.—The last extension granted to the South Staffordshire Tramway Company for the use of steam on their lines between Darlaston and Handsworth has expired. It has been rumoured that the company have secured a further extension of several months, on the understanding that this will be the final one. It is reported that steps are being taken to convene a conference of representatives of the different corporations concerned, and this will be held at an early date, when it is expected that some arrangement will be arrived at on the subject.

Yarmouth.—The surveyor of the Town Council has reported to the Electric Lighting Committee that since the last meeting applications had been received from six customers for 238 lamps, the total number of customers now being 105 for 5,360 lamps. The income for the month of August had been £162. 7s. 8d. The expenditure amounted to £108. 18s. 9d. There had thus been earned beyond cost of production the sum of £53. 8s. 11d. Fuse-boxes and meters were required to the amount of £62. 10s. They would be paid for out of loans. The committee directed the borough surveyor to obtain the goods asked for.

Bath.—The Bath City Council have, upon the recommendation of the Lighting Committee, decided to make an application to the Board of Trade for a provisional order under the Electric Lighting Acts, 1882 to 1890, giving the authority power to take the electric lighting of the city under their own control. At present it is in the hands of a company, who some time since applied for the Council's consent to their application for the provisional order, but this was refused. Alderman Clark, who supported the recommendation of the committee, said he considered it desirable that the city should have power to supply electric energy in the same way as it supplied water.

Battersea.—The special committee appointed by the Battersea Vestry to consider the question of electrically lighting the parish have presented a report on the subject, in the course of which they state that after due enquiry and consultation with Dr. J. Hopkinson, F.R.S, they are not prepared to recommend the adoption of a scheme for utilising the dust destructor in connection with the electric light. After careful consideration they have resolved to invite competitive schemes for lighting the parish, and to offer premiums for the three best. With a view to the Vestry applying to the Board of Trade for a provisional order, the necessary notices

Digitized by Google

have been given for a statutory meeting of the Vestry to sanction such application.

Hove.—The Hove Electric Lighting Company, Limited, are prepared to receive applications for the unallotted portion of the Company's shares and 4½ per cent. debentures. The £5 shares are offered at £5. 5s. each, and the debentures at the price of £103 per £100 debenture. In addition to providing the debenture interest and all other charges, the Company paid a dividend for 1894 at the rate of 3 per cent. per annum on shares. The receipts from customers for current for the first six months of the present year are more than double the receipts for the corresponding period of the year 1894, and the directors confidently anticipate paying a satisfactory dividend for the current year.

Dewsbury.—The Town Council have resolved that the town clerk write to Mr. W. H Preece to ask that he will use all possible expedition in having all the contracts in connection with the electric lighting department brought to a speedy and final settlement. A letter has been received from the Westinghouse Electric Company, with respect to their claim for royalty under the Hopkinson patent, for the use of the three-wire system, and the town clerk was directed to make further enquiries in the matter, and endeavour to arrange for an interview on the subject between the company and Mr. Preece The Council have resolved that it cannot agree to quote a reduced price for the supply of electricity for the lighting of the post office premises.

Liverpool.—The Mersey Docks and Harbour Board give notice that during September a cable will be laid from the Formby Lightship to the Crosby Lighthouse, by means of which electrical communication will be established between the said lightship and lighthouse. In the last session of Parliament a Bill was introduced with reference to the Corporation and the Electric Supply Company's undertaking, but the session came to an end before the measure could be passed. The company's agreement with the Council would in the ordinary course of events come to an end on December 31 this year, but at a meeting of the Special Lighting Committee a communication from the company was read, and it was resolved to extend the term of the agreement for 12 months.

Huddersfield.—The town clerk (Mr. F. C. Lloyd), at the last meeting of the Town Council, defined the law with regard to rights of owners of property and land which was crossed, although not touched, by telephone and telegraph wires. The Town Clerk explained that these owners had exactly the same rights as owners whose property was touched by telephone wire appliances, and could exact sums for wayleave. There was here a question for the Corporation. Overhead wires crossing the streets, he said, were a cause of risk and annoyance to the inhabitants, and they certainly disfigured the town greatly. The Council would require to obtain further parliamentary powers very shortly, and this was one of the points that would be considered by the Parliamentary Committee.

Halifax.—Recently the Halifax Chamber of Commerce made representations to the National Telephone Company respecting complaints in the district as to the inefficiency of the service, the chief grievance being the delay experienced in obtaining trunk communication. It was suggested, among other things that more trunk lines should be laid. The general manager of the company (Mr. W. E. L. Gaine), Alderman Frankland, a director, and the local managers have met a committee of the Chamber at the Town Hall, and the various complaints were fully gone into. Mr. Gaine promised that where possible the grievances should be remedied. With regard to the trunk service, he said the postal authorities would have to be consulted before additional lines could be laid. The company, he added, was wishful to improve the service in the district, and to comply with the wishes of the Chamber.

General Electric Company, Limited.—This Company. who are the owners of Patent No. 3,664, dated February 28, 1891, and entitled "Improvements in Electrical Switches," have granted licenses for the manufacture and sale of the well-known switches called "Tumbler" or "Link" switches (with either a link movement or a heel piece) to the following firms: the Edison and Swan United Electric Light Company; Messrs. Evered and Co, Limited, of London and Birmingham; Messrs. McGeoch and Co., of London and Glasgow; Messrs. Verity and Sons, of London and Birmingham: Messrs. Bayley Bros., of Walsall; and Messrs Tucker and Co., of Birmingham. We have received the new editions of the electric bell and telephone catalogues of the General Electric Company. Both have been considerably enlarged, and no trouble or expense have evidently been spared in getting up good illustrations and descriptions of the various articles listed. In addition to the prices, illustrations, and descriptive letterpress, each list contains a carefully written practical treatise upon its particular branch and a copious index.

Folkestone.—There has been a special meeting of the Corporation to "receive the report of the Special Electric Lighting Committee appointed on September 26, 1894, on the scheme for lighting the borough by electricity, and to consider the same; and to make orders and pass resolutions with reference thereto." Councillor Baker moved that the report be adopted. It was a scheme formulated by Mr. Francis H. Medhurst to cost about £13,000. Councillor Baker went through all the points in the report, and contended that, for all practical purposes, it was as effective as Mr. Parker's scheme to cost £35,000. Councillor Payer seconded. Councillor Thompson then produced a type-written document, which he proceeded to read, interlarding it with long extracts from electrical journals. He eventually suggested, as there was no chance of their coming to a conclusion, the two schemes should be submitted to an expert. This would have involved an outlay of probably 100 guineas. It was therefore moved by Alderman Salter, and seconded by Councillor Harrison, that the matter be adjourned *sine die*, and this was carried.

Morecambe.—The Urban District Council have received the report and valuation of Mr. Parkinson, the electrical engineer appointed by the Council to value the works of the Morecambe Electric Light and Power Company, Limited, and his report on the best system of lighting the town by electricity. At the last Council meeting Mr. Parkinson explained his valuation and system of lighting Morecambe by electricity. It was resolved that an offer be made to the company for the purchase of the plant, parliamentary powers, and undertaking, excluding the gas-engines, gas apparatus, dynamos, belting, and transformers, enumerated by Mr. Parkinson in his report, for the sum of £4.125, such offer being conditional upon the Council obtaining all necessary powers and authorities and also the consent of a meeting of owners and ratepayers of the district.

Windsor.—Councillor Caley enquired, at the last Town Council meeting, if anything further had been heard respecting the electric light. Mr. Atkins (the town clerk's assistant): Nothing. Councillor Caley: Then I suggest that steps be taken immediately to see if it cannot be carried on. I suggest that the Electric Lighting Committee be called together. Alderman Dewe said the last time he saw Mr Lovegrove he said he had received no communication from Mr. Medhurst, and until they heard from him it was of no use to call the committee together. Councillor Caley said he did not know why they were waiting for Mr. Medhurst. The suggestion for him to ascertain the water power was purely his own. He thought they might get on with other matters and leave the consideration of his report until they got it. Alderman Dewe explained that the committee had an interview with Mr. Medhurst and Mr. Liardet, who told them they could save much money by adopting their proposal to use the water power. The committee were expecting a report from these gentlemen, and he could not see how the matter could be settled until that report came.

Manchester.—The Corporation have begun operations which will enable them to provide the electric light to private premises in Oxford-road as far as Whitworth Park. At present the supply of electric light goes no further than the canal bridge near Whitworth-street. It is not immediately contemplated to provide for public lighting, nor is it likely that the extension to Whitworth Park will be completed this winter. The work, however, has already been begun, and operations of a similar nature are in hand in Stretford road and in Downing-street, where it is proposed to carry the light as far as Ardwick-green. A correspondent writes to a local paper: "Permit me to protest against the bad lighting of our Comedy Theatre. From the time of opening the doors until the performance commences the light is a wretched one. When a complaint is made to the officials they reply that electric light is expensive; but seeing that the theatre is supplied with gas also, this explanation is scarcely satisfactory. I think it is only necessary to call the attention of the theatre authorities to this evil to have it remedied, for the sake of the large number of people who prefer to go early to the theatre, and who, like myself, have so far had great reason to complain."

Bury St Edmunds.—The incandescent gas light has been much pushed by a local firm and largely adopted in the shops of the town. It is interesting, however, to note that one of the first results has been the putting in of two small electric light installations, of which one probably, and the other avowedly, has been prompted by a desire to go one point better. The first is the property of a small syndicate and though not yet out of the hands of the engineers (Messrs Crampton and Co., of Cambridge), has been running some little time. It consists of a Crossley gas engine, dynamo, and accumulators, and is intended to supply several shops with light for both business and domestic purposes at a charge of 7d a unit. At present rather more than 150 incandescent lamps have been put in. The price of gas is 3s. 6d. per thousand. The second installation, which is in process of completion, is designed on different lines. It is to consist of about 70 incandescent lamps fitted in a single shop (Messrs. Plumpton and Sons), and will be run only during business hours, so that the number of lamps on will be practically constant. Gas is to be retained for domestic use. The dynamo is driven by a Crossley electric light engine, and accumulators are to be dispensed with. The work has been done by Messrs Laurence and Scott, of Norwich. Other installations are talked of. Up to the present time the Town Council has been strongly opposed to the introduction of the electric light, but now that the private consumer is taking the matter into his own hands there will almost certainly be a change of policy, and probably a scheme of public lighting.

Copper Deliveries during the first fortnight of this month exceeded the supplies by nearly 1,500 tons, so that the statistical position, the *Financial News* thinks, is still very promising for a maintenance of prices American arrivals were again agreeably small, and the imports from other quarters were but moderate. The visible stock is now 53,969 tons, against 55,432 tons at the beginning of the month.—In a copper trade circular from New York, dated September 3, it is said the general trade prospects in the United States continue of a very hopeful character. The coming fall is likely to see an unusual expansion of business transactions. As respects the copper position it is remarked that "there may not be a famine for it, but with the unprecedented demand and every prospect of an increasing consumption for years to come, the most conservative must be convinced that copper is making new history for itself. Electricity is putting in its claims in a most urgent manner, and the popular demand for electric transit will lead to the introduction of the electric railway in many new localities. These electric roads are spreading wonderfully. In the

Digitized by Google

past 20 years it is estimated that the number of miles of railway track electrically equipped in the country has increased from 7,466 to 10,363 miles. These electric railways will transform many outlying districts into centres of activity, and the end of their development is by no means in sight. Long-distance transmission of electrical power has also now become an assured success, and its introduction in various directions in the different countries of the world must have a most important bearing on copper consumption. The outlook for copper is indeed nothing short of brilliant."

Ayr.—The town of Ayr, a corrrespondent writes, is now within measurable distance of the date at which the electric light will be illuminating its principal streets, public works, shops, and many of its houses. It was at one time expected that the current would be turned on for the race meeting, but this expectation is not to be realised, and the period has had to be extended to a time limited to the end of October, when if nothing untoward occurs, it will have largely superseded gas as an illuminant. Under Mr. Hammond and his assistant, Mr. E. G. Pink, who has been appointed burgh electrical engineer, the work has been proceeding during the last 12 months. The generating works occupy a central station on the south bank of the River Ayr, about 100 yards below the railway bridge, which is within the tidal influence Part of the buildings abut on the river, from which they are protected by a concrete wall, and access is had by Mill-street. The buildings are of the usual character, including power-house, boiler-house, and offices. The principal feature is the power-house for containing the generating machinery, which is a spacious building and well lighted. The power is supplied by two boilers, 28ft. by 7ft., fitted with mechanical stokers, and each capable of supplying 200 h.p. The system upon which the installation is based is the high-tension alternating. To generate the current, there are four sets of engines in the power-house. The two principal engines each drive a 100-kilowatt alternator by Siemens and Co., Woolwich, which gives 50 amperes at 2,000 volts. The principal machines are capable of supplying light to the amount of 6,600 8-c.p. lamps, and a 50-h.p. machine 850 8-c.p. lamps. The total amount of light, measured in candle-power, is thus nearly 70,000 candles. The plant may yet be used to work a tramway between Burns's Monument and Prestwick through Ayr, a distance of about six miles.

Cardiff.—Mr. S. F. Walker writes to the *Western Mail:* "I cannot help once more warning the Cardiff County Borough Council that they stand to have even more trouble with their arc lamps during the coming winter than they had during last winter. All the conditions are the same, except that, there being more incandescent lights attached to the supply, and in particular some large buildings, the rectifiers will be even more likely to lose that current at uncertain periods than when they were first started; and, in addition, the arc lamps themselves are likely to give more trouble individually from the wear of the last nine months. Why not take the bold course that will end all their troubles and move the generating station to the centre of the town? As an instance of the different results that may be obtained from the policy I have so persistently advocated, I would instance, among others, the city of Lancaster. There an old pupil of mine is borough electrical engineer. He has laid down a station whose possible output is nearly as large as that of the Cardiff generating station; his scheduled area is considerably larger than that of Cardiff (the area over which his distribution extends); he has spent less than half the amount that has been spent in Cardiff; and he has made a profit on his first year's working, while we stand to lose £6,000. He has done this simply and solely because he has placed his generating station within his scheduled area, and has used low-tension continuous currents in place of high-tension alternating currents. We are not accustomed to look upon cathedral cities as patterns of enterprise or of good management, but in this case certainly the Chicago of the old country might take a good lesson from Lancaster as well as from other towns Few towns have so many natural advantages for the successful and economical adoption of the electric light. Hardly any town has done worse." To this Mr. Frank Baines, of London replies: "I have read with much interest the effusions of Mr. S F. Walker, as published in your columns during the past two or three years, and more particularly the last letter from his pen. It seems to me that there is only one remedy for the defective or alleged inefficient lighting in Cardiff, and that there is only one man in the world who is capable of effectually enforcing that remedy. That man is Sydney F. Walker, and the remedy is for the Corporation to make Mr. Walker a present of the generating station and plant. If this were done, nothing further would be heard from him on the choice of the alternating system in conjunction with rectifiers." At a meeting of the Lighting and Electrical Committee of the Cardiff Corporation a deputation, representing the High-street Arcade Company and the tenants of the shops therein, mentioned the desirability of lighting the arcade by electricity. It was pointed out that the substitution of the electric light for the ordinary gaslight would have a beneficial effect upon the atmospheric conditions of the arcade, and would be a great inducement to tradesmen to become consumers. a number having already signified their intention of using the light on condition that the arcade be so lighted. The committee have instructed the borough engineer to report on the cost by the next meeting. It was stated that the arcade was within the area, and that provision had been made for laying these mains in the application to the Local Government Board.

Exeter.—A report has been made by the city engineer to the sub-committee charged with investigating the details of the question as to the purchase by the City Council of the electric light undertaking. He stated that he found the steam machinery was in good order, and, with the exception of a small high-speed engine, could be economically worked. He considered that the value of the undertaking was £7,556, but recommended that an expert should be called in. Dr. Fleming was consulted, and asked to report whether the Corporation would be well advised to purchase the undertaking for £10,000, and if that sum was the proper value; and if not, whether it would be advisable for the Corporation to acquire the provisional order and the undertaking. He did not think the works as they stood were calculated to do all that would be required of a corporation which undertook electric lighting The plant, with some small possible extensions which he suggested, would not be sufficient to meet more than an additional demand for another 2,000 8 c p. lamps to be added to the circuit, and the limit of the supply capacity would be an additional 8,500 8-c.p. lamps. The general opinion he had formed of the generating station and its equipment was that the station was not laid out in the beginning with sufficient forethought and provision as to future extensions and requirements; secondly, that the general design showed a want of engineering skill, and not sufficient care in the utilisation of the available space; thirdly, that the plant selected, speaking electrically, was not up to date in its efficiency and design; fourthly, that some portion of the plant would have to be replaced by improved and more efficient machines if the undertaking was to be put on a sound basis Having regard to these circumstances, he did not think the undertaking was worth £10 000. With regard to the second question referred to him, Dr. Fleming said if the Corporation either possessed a provisional order or could obtain one he would not advise the purchase of the present electric lighting company's plant on any terms, because he did not think it was sufficiently modern or efficient to render it a desirable acquisition, nor was it capable of the extension which a corporation electric lighting station should be. At the same time he was somewhat reluctant to suggest that the Corporation should abandon the idea of undertaking the supply of electricity, because that might afterwards prove to be a mistake He had carefully considered if the works could be taken over on any terms, and whether they could be made self supporting. If certain suggestions he made were carried out, it was possible to make the gross revenue exceed the gross outlay by £200 or £250. He had made a valuation of the plants and works on the basis that the undertaking could not be of any value to the Corporation at all, unless it could be shown not to be a loss-making concern. His estimate was £7,110, to which must be added the cost of obtaining the provisional order, £426, making a total of £7,536. There is only £20 difference between the estimate of the city surveyor, Mr. D. Cameron, and that of Dr. Fleming. After considering the reports the sub-committee came to the conclusion that it was not advisable to give £10 000 for the works. Their recommendation has been considered by the Council in committee and adopted. After some discussion it was decided to recommend the Corporation to offer the company £7,500 for their undertaking. The Corporation have adopted the report of the sub-committee by 21 votes to 10, and decided that the offer should be made subject to the approval of the Board of Trade, and to the sanction of the Local Government Board to the borrowing of the money.

Tunbridge Wells.—In the course of an article on "Electric Lighting at Tunbridge Wells," in a local paper, Sir David Salomons, Bart., says: Now that the advantages which can be obtained by the adoption of the electric light are within the reach of every inhabitant of this town, it may be desirable to mention a few points in connection with this modern illuminant for the information of those who have not the time or opportunity to follow recent developments of the applications of science. A great deal has been said on the supposed extra cost of the electric light as compared with gas. The charge per unit in this town for electric energy is 6d., and if householders are careful to make use of the easy method of turning off the light on leaving a room and at other times when the light is not required, since it can be switched on again with equal ease when desired, it will be found that the cost is decidedly less than that of gas at its present price in this town, and also less than the cost of lamps and candles light for light The householder should take into consideration the fact that when he adopts the electric light, he not only dispenses with his gas bill, but also with the cost of oil and candles, and these latter are not an inconsiderable item. He must also bear in mind that, when the new illuminant is installed, he obtains a better light in his room than he did in the olden days, and that he also preserves his decorations. It is only natural that a timid body like gas shareholders should feel nervous at seeing the introduction of the electric light. This, in itself, might be taken as a sign that they believe their own wares are inferior to the new ones, but the advance of the electric light will not be stopped by any action on their part any more than was the advent of railways retarded by the coachdrivers of those days. But at least I can hold out a little comfort to the gas shareholder when I say that the gas-burners which will be replaced by the electric lamps will not seriously affect the company's returns. In private houses, the number of electric lamps which are likely to be inserted will, for the sake of convenience, be greatly in excess of the present number of gas-burners, for the reason that the sitting-rooms will use the new light where in most cases gas does not now exist. In shops no doubt the electric light will almost entirely supplant gas, owing to the greater effect obtained in the display of goods. On the other hand, gas stoves of proper construction are likely to increase in number in the town, for the very reason that the electric light makes its appearance. In the City of London, where the gas interest is vastly more powerful than at Tunbridge Wells, the attempts to damage the new

Digitized by Google

illuminant were powerless. Even the fuss which has been made over the incandescent lamp burner was of no avail. The light from such burners is injurious to the eyes, which I can personally answer for, having used it myself and been obliged to give it up. Besides this, although it is economical when calculated by candle-power, economical burners are not yet produced, and therefore the advantage on this score is a pure delusion. I have had myself experience of gas in London succeeded by electric energy sold at 8d. per unit and later at 6d. per unit. I can testify to the fact that the electric light bill when the unit was 6d. was less than the gas bill. In the City of London, although the price per unit is 8d. for the reason that there are only 5½ working days in the week instead of seven, as in other places, yet I have many testimonials showing that the electric light bill was less than that of gas in those offices and warehouses where due regard was given to turning the lamps on and off as they were required. There is, however, one point which is of great interest to householders, and appeals more forcibly to the trade and landowners of this town than perhaps any other. It is that of health. At the present time the death-rate of Tunbridge Wells is under 14 per 1,000 and I believe this can be greatly reduced by the general use of the electric light. In the case of the light given by electric incandescent lamps, the tendency to injure health and shorten life is totally absent. Supposing the electric light were to cost double the price of gas, which is not the case, there would still be a large saving in doctors' and chemists' bills, a better temper prevailing in the household, and no dread of long winter evenings. Work could be continued after dark without distress, book-bindings will remain as good fifty years after leaving the binder's hands as on the day they were bound, furniture and decorations will not be injured, and the householder will find himself richer every year due to these causes, quite apart from the enjoyment of better health, which will enable him to enter on his business duties with that vigour and clear mind which is absent from the inmate suffering from poisonous and gas-vitiated air.

PROVISIONAL PATENTS, 1895.

SEPTEMBER 9.

16826. **Improvements in the electrolysis of saline solutions.** Emile Andreoli, 18, Somerleyton-road, Brixton, London.

SEPTEMBER 10.

16866. **Improvements in arc lamps.** Edward Jesse Piper, 34, Victoria-street, Westminster.

16897. **Improvements in holders and supports for electrical candles.** Hugo Hirst and William Everett Gibson, 73, St. Stephen's-road, Upton Park, London.

16898. **An improved wall socket and plug for electric lighting and kindred purposes.** Gustav Binswanger, 73, St. Stephen's-road, Upton Park, London.

16910. **Improvements in and relating to power-transmitting mechanism for the power shafts of electric and other high-speed motors.** Daniel Stephen Regan, 77, Chancery-lane, London. (Complete specification.)

16918. **An improved junction coupling for electric lighting installation.** Hahnemann Adolphus Cutmore, 172, Queen Victoria-street, London.

16924. **Improvements in electric fire alarms.** Charles Darwin Tisdale and John Duncklee Gould, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16925. **Improvements in electric fire alarms.** Charles Darwin Tisdale and John Duncklee Gould, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

16939. **Improvements in electric locomotives.** James Devonshire, 70, Chancery-lane, London. (Edwin W. Rice, jun., United States.) (Complete specification.)

16940. **Improved electrical tool.** Fredric Joseph Warden-Stevens, 70, Chancery-lane, London.

16950. **Electrolyte baths, appliances, and system.** James Henry George, 44, Broad-street, New York, U.S.A.

16952. **Improvements in incandescence electric lamps.** Walter Rowbotham and Hymen Levetus, 45, Southampton-buildings, Chancery-lane, London.

SEPTEMBER 11.

437A. **Improvements in and connected with arc lamps.** John Brunswick Barton, 18, Southampton-buildings, Chancery-lane, London. William Jandus, United States). (Date claimed under Patents Rule 19, January 7, 1895.)

17004. **Improvements in and in the method of constructing incandescent electric lamps.** Percy Richard Julius Willis, 55, Chancery-lane, London. (Robert Greer, United States.)

SEPTEMBER 12.

17058. **Improvements in periodically ringing bells and sounding whistles, syrens, or the like, and registering the same, and in electrical apparatus therefor.** Frederick Herbert Berry, 168, Fleet-street, London.

17063. **Improvements in electric smelting.** Thomas Leopold Willson, 55, Chancery-lane, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, February 20 1895, being date of application in United States.)

SEPTEMBER 13.

17123. **Improvements in linked suspensions for electroliers, electric light pendants, and the like.** Hugo Hirst, 73, St. Stephen's-road, Upton Park, London.

SEPTEMBER 14.

17205. **Improvements in machinery or arrangements for lifting, lowering, carrying, or transporting leads, actuated by electricity.** John Audley Frederick Aspinall, 5, Market-street, Manchester. (Complete specification.)

17210 **Improvements in the manufacture of electrical resistances.** Augustus John Marquand, Emmanuel Hancock, and David Lowdon, 24, Southampton-buildings, Chancery lane, London.

SPECIFICATIONS PUBLISHED.

1891.

19071.* **Incandescent lamps.** Langhans. (Amended specification.)

1893.

6780 * **Secondary batteries.** Doubleday. (Sussmann.) (Amended specification.

1894.

12045. **Secondary batteries.** Schanschieff.

16418. **Telephonic apparatus.** Cerpaux and another.

16999. **Electric switch.** Cowper-Coles and Alliott.

17761. **Arc lamps.** Brockie.

17922. **Arc lamps.** Immler.

19877. **Electrically-heated grills.** Schlinder.

20017. **Arc lamps.** New and Mayne.

1895.

13348. **Distributing power by electricity.** Royce and Claremont.

13380. **Electric lighting.** Moskowitz and others.

13411. **Distributing power by electricity.** Royce and Claremont.

13416. **Electric lamps.** Walters.

13635. **Electric gas lighters.** Grier and others.

13978. **Stopping electrically-propelled cars.** Bonta.

14014. **Electric switch.** Jones. (Stuebner and others.)

14049. **Arc lamps.** Higham

14114. **Electrical apparatus.** Hessberger.

NOTES.

The New Taxes upon Gas and Electric Light in Italy, particulars of which were given in our issue of July 12 (page 29), enter into force on November 1, 1895.

Obituary.—Mr. Paul Prince, superintendent of the Midland Railway Signalling Department, whose death occurred on Tuesday, was the originator of some important electrical patents.

Telephony in Mexico.—A Mexican newspaper urges that the further development of the telephone industry should be stopped, "as it will ruin railways and hotels by rendering travelling unnecessary"!

Telegraphs in Nyassaland.—The *British Central Africa Gazette* states that, in addition to his administrative work, Major Forbes is charged with the completion of the Blantyre-Tanganyika telegraph line.

The Bordeaux Exhibition.—It is rather curious that the explosion of a gas-engine at the exhibition at Bordeaux should cause a serious fire to break out and totally destroy the electricity pavilion.

A Curious Accident is reported from the Grand Rapids, Michigan. A little girl was playing at the corner of a street, when a lamp trimmer threw a carbon from the top of the electric light tower. The missile fell 150ft., striking the child's right eye, and unfortunately destroying the sight.

The Lighting of the Holstein Canal.—Herr Bänsch, the engineer of the Kaiser Wilhelm Canal, has gone to Rendsburg with a view to investigating the working of the electric lighting of the waterway. A squadron of first-class ironclads is, it is stated, about to make a trial trip through the canal.

French Telephonic Courtesy.—A Reuter telegram from Paris says that during the Marquis of Salisbury's stay at Dieppe the French Government has shown the greatest courtesy to him. M. Hanotaux, the Minister for Foreign Affairs, offered to have a telephone laid between the Châlet Cecil and the British Embassy in Paris.

Telegraphs on the Amazon.—A party of English engineers have begun surveys of the Amazon for the new cable between Pará and Manáos. They are accompanied by a Mr. Reidy, who will arrange for the necessary cable stations along the river. It is expected that the work of laying the cable will be begun before the end of the year.

Electric Staff Instruments.—Major Marindin has recommended the directors of the Dublin, Wicklow, and Wexford Railway Company to make a trial of an invention which, on lines worked by the electric train-tablet, locks the starting signal at a station at danger until a tablet has been withdrawn at this station. He has no doubt that this invention could easily be made applicable to electric staff instruments.

A Narrow-Gauge Electric Locomotive.—We regret that a few errors crept into the article on this subject in our last issue. The locomotive when loaded and climbing the heaviest grade takes 45 amperes, not 450. The rail bonds have split cylinders at each end, which are expanded into contact with the web of the rail. Messrs. Holroyd Smith and Ravenshaw are to be congratulated on the way they carried out the above work at Chatham.

Lighting in Italy.—*L'Elettricità* of September 22 says that the experiments with the oxy-hydrogen light as an illuminant at Spoleto, in Perugia, are being watched with considerable interest and satisfaction. The light, which is described as being "perfectly white like sunlight and not starlike as in the case of the electric arc," is obtained by the decomposition of water by electricity, the perfection of the process being attributed to Prof. Garuti Pompeo.

The Rustchuk-Sofia Telephone was opened at the beginning of the present month. It is proposed to extend it to Bucharest. The telephone line between Sofia and Belgrade is already in course of erection, in connection with the projected Belgrade-Budapest wire. Should the Bulgarian efforts to establish the planned Sofia-Constantinople line be successful, there would then be uninterrupted telephonic communication between Berlin and the Turkish capital.

A Telephone War is said to be raging in Kansas between the Missouri and Kansas Telephone Company and the Harrison International Telephone Company. The "battlefields" are principally Topeka, Leavenworth, Wichita, and Salina. "The war has even run over into St. Joseph and Carthage, in Missouri. In Wichita the Missouri and Kansas Company has just offered telephone service at 30dol. for residence and 36dol. for business houses for a year. In Salina, telephone service is practically given away."

The Cardiff Exhibition.—The Cardiff Fine Art, Industrial, and Maritime Exhibition will be opened in May, 1896, under the patronage of her Majesty the Queen and the presidency of the Right Honourable Lord Windsor, lord-lieutenant of the county of Glamorgan, and continue open during six months. Among the sections will be one devoted to "machinery, electricity, and local and general industries," while another will embrace "scientific instruments, specimens, and inventions." The hon. secretary of the exhibition is Mr. Walter Cook, of St. Mary-street, Cardiff.

Chesterfield and Midland Counties Institution of Engineers.—A special general meeting of the members of the institution (Mr. Emerson Bainbridge, M.P., president) will be held in the Stephenson Memorial Hall, Chesterfield, on Saturday, October 12 proximo, at 3 p.m., when the president will deliver an address, and the following papers, amongst others, will be open for discussion: "Continuous-Current Dynamos and Motors: Choice of Plant, Fixing, and Driving, usual Faults and their Remedies," by Mr. Lancelot W. de Grave (adjourned from Nottingham meeting, March 16, 1895); "Photometric Value of and Notes upon Various Illuminants used in Mines," by Mr. A. H. Stokes (adjourned from Warwick meeting, July 13, 1895).

The Cost of Incandescent Lamps in Germany. The *Zeitschrift für Beleuchtungswesen* gives the following as the net cost of manufacture of electric incandescent lamps in Germany: globe 0·48d., platinum 0·96d., filament 0·24d., cement and attachment 0·24d., glass neck and vacuum tube 0·18d., total 2·1d.; working the filament 0·24d., conductors 0·12d., fixing filament on conductors 0·06d., preparing for vacuum 0·3d., vacuum 0·3d., photometry 0·12d., fixing neck and soldering 0·24d., cleaning and testing 0·12d., total 1·5d.; general expenses 0·24d., current 0·24d., gas 0·06d.—total 0·54d.; total cost per lamp, 4·14d., to which add 10 per cent. for breakages, making 4·554d. per lamp. The cost of packing and that of heating and lighting the works, together with the interest on capital, bring this up to 5·346d. per lamp.

Electricity in the Russian Army.—The Russian army authorities, *L'Etincelle Electrique* of September 20 says, have decided to establish a scientific branch of the service under the direction of a lieutenant-general, two

Digitized by Google

major-generals, and five officers of lower grades, whose business it will be to work out the applicability of electrical discoveries to war purposes. In addition, an electrotechnical school has been instituted under the direction of a major-general for the purpose of giving a 19 months' course of instruction to 35 lieutenants and sub-lieutenants of Engineers. This school will also serve to train an electrical company recruited from mechanics and from selected non-commissioned officers of Engineers, who, after passing through the school, will go back to their regiments and there be available as instructors.

Sir David Salomons and Tunbridge Wells.—An effort is being made to induce Sir David Salomons to again consent to be mayor of the borough of Tunbridge Wells. The Reception Committee of the Town Council, who organised the arrangements last year, have decided to present a memorial to Sir David, acknowledging the many good services that he has already rendered the borough, and expressing the hope that his worship may see his way to continue in office for another year. The honorary secretary has communicated with various institutions, including the Tradesmen's Association, who have unanimously decided to support the Reception Committee, and we believe that the memorial is being extensively signed by all classes. By the bye, when the mayoress formally opens the new central electric lighting station next month, all the local bodies will join in an imposing procession round the borough.

Electric Traction in London.—Every week seems to produce a new London railway scheme, the latest report being that a syndicate proposes to take over the London, Chatham, and Dover Company's Metropolitan Extension line from Ludgate-hill to Victoria in order to experiment with electric traction. The report, which seems to emanate from the City, states that the Chatham Company's Ludgate-hill-Victoria line offers a ready-made track very suitable in every way for electric power, and that it could be completely isolated from the main line, while the cost of electric equipment would be small compared with the enormous increase of traffic and of net receipts obtainable. A proposal, it is said, is about to be made to the Chatham Company to lease the section in question for a term of years, re-equip it, and work it on shares; and the projectors believe that their offer to the company will be so tempting as to ensure serious consideration.

The Federated Institution of Mining Engineers. The annual general meeting of this institution was held last week at Hanley, Mr. W. N. Atkinson, H.M. inspector of Mines for North Staffordshire, occupying the chair. Amongst the "objects of interest" shown at the gathering were the following: "Best" miners' safety lamp, with electric lighting apparatus, by Messrs. Ackroyd and Best, of Morley, near Leeds; signal bells, electric signal bells, specially designed for colliery use (damp and dust proof); telephones for colliery work, safety lamps, with Messrs. Heath and Frost's patent paraffin burners; shaft and porch safety lamps, and various mining specialties, by Mr. H. M. Edwards, of Wakefield. At the conclusion of the meeting the members were divided into two parties—one visiting the electricity works at Hanley, where they were received by Mr. E. J. Hammersley, the Mayor, and Mr. Lobley, the borough engineer, the other going for a drive through Trentham Park.

Prof. S. P. Thompson and the Finsbury Technical College.—The evening classes at the Technical College, Finsbury, will shortly recommence, when the introductory lecture of the advanced course on electrotechnics (lighting and power) will be given by Prof. S. P. Thompson on rotating magnetic fields. The subsequent lectures of this course will be given by Mr. O'Keeffe and by Prof. Thompson, who will take up special topics, such as electric meters, design of alternate-current machinery, etc. The Wednesday evening course by Prof. Thompson and Mr. E. Thomas will deal with the current, its measurement and its application to the electromagnet, etc. There will be the usual practical classes in the laboratories, and Mr. E. Rousseau will later take a laboratory class on electrotyping and electro-plating. In the department of mechanical engineering, Prof. Perry will give on Thursday evenings, in addition to the ordinary course on practical mechanics, a short special course on thermodynamics as applied in engineering.

Westminster Street-Lighting.—There was a long and well-illustrated article on this subject in a recent issue of the *Westminster Times*, in which the present unsatisfactory state of the street-lighting was commented on. It is doubtless a fact that the lighting in many of the streets of Westminster is out of date and insufficient, but the author, in dealing with proposed improvements, should not neglect the arc lighting system. He carefully compares the cost for gas and electricity where the Welsbach burners and incandescent lamps respectively are used, and draws conclusions in favour of the gaslight. The proposed arrangement of using a group of 16-c.p. incandescent lamps for large streets has been condemned again and again by the technical Press as uneconomical. The author assumed a supply at 3d. per unit and arrived at a total cost of £9 per annum for such a group giving 48 c.p. If, on the other hand, he had tried arc lighting, he could for £27 have put in an arc lamp giving at least 1,000 c.p., which could replace a considerable number of small lamp-posts, and which would give a better light than gas, and also more economy, light for light.

Electrical Progress in India.—The debate on the Electric Lighting Bill in the Bengal Legislative Council was remarkable, says a correspondent, chiefly for a "learned" discourse on the development of electricity by the Honourable Mr. C. E. Smyth, which in a lecture-hall, and delivered to students, would no doubt have been highly instructive, but wedged into a debate in the Legislative Council was singularly out of place. How, the correspondent adds, it could benefit those anxious to understand the bearings of the Bill on the civil rights of the people to be told that "the development of electric science in its application to the practical needs of human life may be considered to date from the time of Faraday, whose career ended about the middle of the present century," it is hard to understand. A commencement has at length been made with the Colombo electric tramways, the terminus of which has been fixed opposite the Grand Oriental Hotel, and near the P. and O. offices. The General Post Office at Colombo was, moreover, lighted by electricity last month, and the effect of the new illuminant on the first night is described by a local paper as "grand."

Church Electric Lighting in England.—A correspondent who, we are glad to see, signs himself "A Regular Attendant," writes from Tunbridge Wells: "The electric light, having now been used for three Sunday evenings at Mount Pleasant Congregational Church, is pronounced by all the usual worshippers with whom I have come into contact to be an unqualified success; and seeing that other churches in the town are thinking of adopting this illuminant, it may not be out of place to say what the effect is in the pulpit, gallery, and pew. The Rev. Cowper Smith has given me permission to say that he, in every respect, has received the greatest possible comfort from the introduction of the light; in fact, he does not now feel more weary on the Monday than any other morning, and

Digitized by Google

the light as arranged in the pulpit is practically perfect for reading purposes. The organist, Mr. Starmer, pronounces the light a great boon, and says that the pitch of the instrument holds good and in tune to the very end of the service without variation. The choir (which, with the organ, are situated in the gallery and opposite end to the pulpit) are more than satisfied with the extreme comfort of the evening services through the cool and pure atmosphere. The seat-holders, too, are well satisfied with the change."

Telephone Reform in France.—Telephonic communication will shortly be conducted under more favourable conditions in France. According to *L'Eclairage Electrique* of September 14, decrees have just been signed by the Minister of Posts and Telegraphs which will come into force on January 1, 1896, and which will remove from the Government regulations a number of provisions which hitherto served to harass the public and restrict the use of the telephone, to the detriment not only of the subscribers but to the finances of the State. The charge for conversations exchanged between two systems within a radius of 25 kilometres(16 miles), starting either from the house of a subscriber or a telephone office, will be reduced from 50 to 35 centimes. Similarly, the rate for a conversation over a single system, which in Paris and a great number of towns costs 50 centimes, is to be reduced to 25 centimes. The duration of a conversation will be limited to three minutes, statistics having shown that this was the average period at the higher price. The extension of the radius of communication at the reduced tariff (25 centimes) will, moreover, entail the suppression of the subsidiary systems, the existence of which has been the cause of so much complaint. These will henceforth cease to exist, both in the environs of Paris and in the departments, and all systems will be placed on the same basis.

The Telephone Service.—Following the conference at Halifax on the telephone service in the West Riding, a meeting of representatives of the Chambers of Commerce of Bradford, Leeds, Huddersfield, Wakefield, Dewsbury, Batley, Keighley, Morley, Birstall, and Cleckheaton has taken place at the Dewsbury Town Hall. The proceedings were private, but we understand that Mr. George Daniel Cullingworth, of Dewsbury, was elected to preside, and that Mr. A. Firth, of Halifax, reported what had taken place at the conference to the effect that the National Telephone Company's representatives said that it was impossible to make a reduction in the annual charge for instruments, and that as to trunk lines it had been suggested that the chambers of commerce concerned should endeavour to prevail upon the Postmaster-General to combine the areas of Bradford, Leeds, Dewsbury, Wakefield, Halifax, and Huddersfield into one, the wires to be local and not trunk lines. This was approved, and it was agreed to memorialise the Postmaster-General and to ask him to receive a deputation on the subject, the meeting in the meantime being adjourned.—The Postmaster-General's report with regard to telephones says: "The negotiations with the National Telephone Company respecting the areas within which the operations of the company are for the future to be restricted and for the settlement of an agreement for carrying into effect the policy set forth in the Treasury minute of May 23, 1892, have been brought to a conclusion, and the drafts of the formal agreements with the licensees were laid on the table of the House on August 7 last. The total amount spent out of the million authorised by the Act of 1892 was £355,678 at the end of the financial year."

Electricity and Fires.—Mr. William McDevitt, chief of the electrical department of the Philadelphia Underwriters' Association, lately gave an illustration of some of the ways in which fires may be caused by electricity. The first danger, he said, was that arising from the common practice of grounding telephone wires on gas-pipe. A bad connection is generally made—quite sufficient for telephone purposes—and, if the telephone wire be crossed with an electric light wire, the larger current meeting resistance at the ground connection heats the joints, punches a hole in the gas-pipe, and the arc formed lights the gas. Mr. McDevitt gave a demonstration of the gas and insulation on the wire burning simultaneously. He also exhibited a section of gas-pipe that had caused a fire in this way. The wires in the sockets of electric lamps are liable to touch the casing, when an arc may be formed. For this reason no drapery should be used around the lamp sockets. The advantage of utilising metal conduits with insulated lining through which to run the wire was shown, a wire outside being dangerously heated, while from that inside the conduit there was no risk. A caution was given against the rough handling of flexible cords used for electric lights as a common cause of short-circuits and fire. There were, he remarked, other dangers due to ignorance on the part of the general public of the character of the electric current. In one case on record the walls of a room were upholstered with material in which were interwoven a large number of metal threads. These were in contact with the electric light wires, and when the current was turned on the whole room was set ablaze. An obscure danger from frictional electricity has been traced. Sparks may be caused by shuffling the feet on carpet or by the rubbing of silk. Where benzene is used to clean such materials, a spark thus caused may give rise to a dangerous fire. It is believed that some benzene fires have originated in this manner. Another cause of fires is the unreliability of fuses. They are put in the line to be burnt out when an excessive current is turned on, but, like safety-valves, they do not always work. If they fail to fuse, a dangerous current may be carried along the line. To obviate this danger, Mr. McDevitt added, a standard should be adopted.

Prof. Fleming on Increased Supply Pressure.—Prof. J. A. Fleming, writing from the Electrical Engineering Laboratory, University College, W.C., contributes his quota to the St. Pancras discussion, which is reproduced in another column. He says: "The discussion on the subject of increased pressure for the electric supply and some possible objections to it has a very practical side to it. The public electric supply has up to now been given in London and most provincial towns either by the alternating-current system, in which the electric energy is delivered at a high pressure to transformers, placed in the houses or in certain special localities, by which it is transformed down to currents of lower pressure for delivery to customers, or by the continuous-current three-wire system, in which a certain electric pressure, generally of 100 or 110 volts, is maintained between the intervals of three insulated conductors laid in the ground. If, for simplicity, these three conductors are called A, B, and C, theoretically there should be 100 volts pressure between A and B and 100 between B and C, and all three should be insulated from the earth. As a matter of fact, it is difficult for the supply companies using mains of a certain type to preserve perfect insulation all over their systems of conductors, and if one of the outer conductors, say C, becomes earthed, the other outer conductor, A, will be raised to a pressure of 200 or 220 volts above the earth. All electric fittings used in houses, such as lamp sockets, switches, motors, and the like, are, even on the present systems of electric supply, exposed to the chance of

Digitized by Google

having to bear an electric pressure of 200 or 220 volts between some portions of them, and ought all to be so made and tested that they can stand this pressure safely. The question has been much debated whether there would be advantage or disadvantage in earthing the middle wire of the three-wire systems of supply; but it is clear that if any of the three-wire systems of electric supply propose to give a 200-volt pressure between each side of the system, making 400 over all, a more severe system of inspection and testing of ordinary house electric fittings will have to come into force. If, on the other hand, it is merely intended to extend in London the outer members of the three-wire system of conductors and to use 200-volt lamps in these outer districts of the supply area, then the state of affairs, electrically speaking, will be no worse than it is at present."

Technical Education.—Nowhere in Great Britain, apparently, is so much attention devoted to the very important subject of technical education as in Liverpool and its suburbs, where both the Earl of Derby and Sir A. B. Forwood, M.P., have recently been expatiating on the theme. Lord Derby, who was present at the distribution of prizes to the successful students of the Liverpool School of Science, Technology, and Art during the past session, remarked that "science is now diffused through the length and breadth of the land, and ample response is being given to the noble manner in which municipalities made grants for technical education purposes." Sir A. B. Forwood, in opening the session of the Waterloo Technical Instruction Classes the other day, remarking on the facilities afforded by towns for technical education, said that Birmingham was spending £50,000 on a central institution; Manchester, £130,000; Salford, £55,000; a poor place like West Ham, in the East of London, £40,000; Wigan, St. Helens, and Derby, £20,000 each; whilst Liverpool was having plans prepared which contemplated an outlay of £80,000. Again, at the annual award of prizes to students attending the classes of the Technical Instruction Committee of the Wavertree District Council, Mr. J. N. Stolterfoht said that a class in electricity would be commenced, and that he hoped that the committee would find this experiment a success, because if technical instruction were to be given, it should be in those things which were applicable to every-day life. The chemical class, he observed, had been a failure, and this was to be regretted, as chemistry and electricity were the two great motive powers, the great subjects of study for the improvement, he might say, of science and art in the present day; and on that account he trusted that the electricity class would be successful. Finally, so far as Liverpool is concerned, at the yearly distribution of prizes to the students of the Toxteth Park Technical Instruction Committee, it was stated, on the authority of Principal Rendall, that higher technical education at University College had been invaluably reinforced, and that an entirely new department in electrical technology had been created and maintained. The school of art in Mount-street had, moreover, been placed in a sound financial position, and the first school of architecture and the applied arts in the United Kingdom had been founded. Other centres of population are, of course, also doing excellent work in the direction of scientific education. We note especially that electric lighting now forms one of the subjects taught at the Heriot-Watt College, Edinburgh, in addition to the stereotyped electricity and magnetism and telegraphy and telephony.

Electrical Interference.—Two methods of avoiding or overcoming electrical interference were discussed by Mr. Abbott in his paper, recently read before the North-Western Electrical Association at Chicago — namely, complete metallic circuits, and the introduction of special return feeds from dangerous points. In his paper on "Additional Solutions of the Electrolytic Problem," Mr. Abbott further considers this important subject. To begin with, he disposes of the suggestion that corrosion could be avoided by operating the railway circuit as a three-wire system, pointing out, first, that a double track is essential, so that the trolley wires may serve as the outer mains, while the ground and the rails play the part of the neutral wire. Of course, this of itself would make the expedient unsatisfactory, as it would exclude all of the many single-track installations from consideration. Another objection is that it would be impracticable to arrange the load on the two sides of the railway to a complete balance, and in so far the system is out of balance the current must return through the rails and ground. Besides, as the load on the two sides of the system is constantly varying over the entire length of the road, the current in the neutral conductor will correspondingly vary, and will in this way spread the injury to underground structures over a much larger territory, and render it impracticable at any time to determine where injury is about to take place. Mr. Abbott considers Mr. Brown's arrangement of station machinery a partial solution of the problem, but he does not look upon it as a complete cure. A plan proposed by Mr. Farnham is accepted with favour by Mr. Abbott, but he does not hesitate to show his belief that it will be rejected by railway companies, owing to the expense which the system entails. He reminds the managers of railway companies, however, that it merely remains for them to face the inevitable position that they must either design railway lines in such a manner as to obviate the damage to existing underground structures, or to go out of the business. In conclusion, he points out that it is absolutely certain that the time is rapidly approaching, if it be not already at hand, when no franchises will be granted to electric railway companies that do not contain a provision fixing upon the railway companies all responsibility for injury which may later be attributable to electrolytic action. He reminds them that in many instances the damage done by existing railway companies has formed a basis for legal proceedings, in every instance to the defeat of the railway company, and he admonishes them to look the situation squarely in the face and take such steps as in the future will relieve them from disagreeable responsibilities of this kind. He concedes to the telephone companies no privileges or advantages not enjoyed by the railways, and he insists that responsibility for damages be placed wherever it belongs. The full paper is printed and illustrated in the *Western Electrician* of August 31.

Compounding Dynamos for Armature Reaction with Converters.—Since the paper by Prof. Elihu Thomson was read before the meeting of the American Institute of Electrical Engineers, at Niagara Falls, on the subject of compounding dynamos for armature reaction, there has been some discussion among electrical engineers regarding the early history of the theme. A representative of a Chicago journal recently had an interview in Boston with Dr. W. P. Freeman, who made deep researches into this matter in the pristine days of electrical invention. Dr. Freeman was asked to state, as nearly as possible, when he was able to present a practical demonstration of the converter system, and he replied: "In 1881 I perfected a machine on a principle of a compound dynamo for armature reaction which produced five arc lights or 40 incandescent lights, and I used in circuit a pole-changer and induction coils, or converters, as is better known at the present time. When the incandescent lights were used the machine delivered 2,500 volts and 15 amperes. There were two converters, each about 12in. in length, and I connected these two in

Digitized by Google

multiple circuit, and dropped the voltage, as I remember, to either 50 or 75 volts, and ran 40 incandescent lamps, a part of which were Maxim, with a filament often called 'M' or 'W.' I had this on exhibition for three months or more at my factory, 43, Center-street, New York City. A large number of capitalists came in during that time to investigate the system, and I finally made an arrangement, and sold to W. F. Jobbins, of New York City, what was known at that time as the sub-dividing device of the electric light system, reducing a high voltage to any required voltage, and which was supposed at that time and talked of as being a wild idea, and Mr. Jobbins did not consider it of much importance. I therefore added to the same agreement the sale of the thermostat invention, which I was manufacturing, for one-fifth interest in the Jobbins Manufacturing Company's Works. In 1883 I constructed two machines, one a direct-current machine and the other an alternator. These machines were practically the same as the machine I made in 1881, except the variations which were made to facilitate winding, and also to bring about a more perfect and even saturation of the magnetic flux. During that year I sold upwards of 20 of this type of machines, which were much smaller than the first two manufactured, but which produced 20 incandescent lights of 16 c.p. In 1886 I made still a further improvement upon the previous design, since when I have manufactured several hundred small machines, and on March 27, 1888, I received a patent, No. 268,737, which proves to my satisfaction that these are the fundamental principles of this system as claimed by me; and according to my patents I do not see where a multipolar-field machine can be used where only one-half of the pole-pieces are wound, without infringing upon my patent. One of the claims allowed me was 'the combination of a multipolar field magnet and multipolar iron armature corresponding in number of arms, or polar extensions, and having only half its total number of arms wound with generating conductor and commutator.' I do not consider this machine as an emergency machine, but one which is practical from every standpoint, as it can be made in all sizes, and will govern itself within 2 per cent. with a variation in speed of the armature of at least 10 per cent. without overheating."

A Year of British Telegraph Work.—According to the report of the Postmaster-General on the operations of the Department for 1894-95, during the year under review 71,589,064 telegrams of all kinds were forwarded in the United Kingdom, being an increase of 689,566, or 97 per cent. Of these, 58,907,408 were ordinary inland messages, while 5,937,715 foreign telegrams were dealt with, being an increase of 255,890; but there was, it should be noted, a decrease of 178,905 in the number of Press messages. The deficiency on this Department during the year amounted to £452,803, compared with £477,327 in the previous year. The postal and telegraph services together showed an increase of £341,000 in receipts and of £274,000 in expenditure, or a financial improvement of £67,000. The whole chapter of the telegraph service is, however, a critic says, manifestly rather a sore subject with the Post Office, which still chafes under the financial burden imposed on it by the original purchase of the telegraphs. The development of business has been extraordinary. In 1870-71, the first year after the transfer of the telegraphs to the State, the number of telegrams forwarded throughout the United Kingdom was 9,850,000. It gradually rose to 39,140,000 in 1885-86—the year in which, on October 1, 1885, the minimum charge for an inland telegram was reduced to 6d. In the following year it exceeded 50,000,000, and it now stands at over 71,500,000. Not less remarkable is the progress attained in efficiency and rapidity of transmission. One of the appendices to the report contains a brief "Historical Outline of the Telegraph Service since 1870." In this it is stated that "in 1870 a speed of from 60 to 80 words a minute was the highest that could be attained in the working of the Wheatstone automatic apparatus. At the present time a speed of 600 words per minute has become possible, and the working speed of 400 words is the fixed standard for certain circuits. . . . Two copper wires between London and Dublin are working on the duplex system at even 300 words per minute, whereas under the conditions of 1870 they would only have given about 40 words in one direction as a maximum." These and similar results are cited by the Post Office as a sufficient answer to the contention urged at the time of the transfer that the possession by the Government of a monopoly would tend to discourage invention. Many of the improvements resulting in the present rapidity of transmission have been adopted from outside, but many others have been devised within the Department, and it must be acknowledged that the Post Office is now probably one of the best schools of practical telegraphy in the world. But the financial results of this remarkable progress are considerably less satisfactory. In 1888-89 the receipts from telegraph business were £2,129,965, and the expenditure was £2,041,261; but as the annual interest on capital expended was £353,787, the resulting deficit was £265,183. In 1893-94 the receipts had risen to £2,579,206 and the expenditure to £2,757,645, while the interest on capital had fallen to £298,888, thus showing, as we have already seen, a deficit of £477,327. In 1894-95 the interest on capital was the same as in the previous year, but the receipts increased in a slightly larger proportion than the expenditure, and the deficit was thereby reduced to £452,803. Thus it appears that in the last seven years the expenditure has gradually risen in excess of receipts, so that whereas in 1888-89 there would have been a small surplus of receipts over expenditure, independently of the amount charged as interest on capital, there is no such surplus in 1894-95, but a deficit of £153,915, which, added to a charge of £298,888 for interest on capital, makes up the total deficit of £452,803. It is true that the deficit of the previous year was £25,000 larger, but, the critic remarks, it is far from satisfactory to find that, even if the interest on capital could be finally wiped out, the telegraph service would still be worked at a loss. In 1888-89 the number of telegrams was 57,765,347. The receipts from these were, as we have shown, £2,129,965, and the expenditure was £2,041,361. In 1894-95 the corresponding figures were—number of telegrams, 71,589,064; receipts, £2,675,414; and expenditure, £2,800,329. Thus, while the number of telegrams has increased by a little under 24 per cent. and the receipts by a little over 24 per cent., the expenditure has simultaneously increased by no less than 37 per cent. This result is due to various causes, among which the low rate at which Press telegrams are transmitted—practically not more than 4½d. for 100 words—is credited with a loss estimated at £300,000 per annum. "Moreover," the appendix to the report says, "new influences inimical (temporarily, if not permanently) to financial success have come into play—namely, the reduction of the tariff in 1885, the increase in the pay of the staff, and the competition of the telephone companies for local traffic." For the rest there is no little force in the concluding paragraph of the appendix already quoted: "The Post Office has to admit a deficit on the working of the telegraphs, but its 71,000,000 telegrams bear testimony to the value of the service which it renders to the public."

AN IMPROVED PORTABLE PHOTOMETER.*

BY W. H. PREECE, C.B., F.R.S., AND A. P. TROTTER, B.A., A.M.I.C.E.

When light falls upon a surface that surface is said to be illuminated. The illumination depends simply upon the light falling upon the surface, and has nothing to do with the reflecting power of the surface, just as rainfall is independent of the nature of the soil. As a rain-gauge receives the full amount of rain when it is placed horizontally, disregarding wind, and receives less when it is tilted, so a surface is fully illuminated when it faces the source of light, and is less fully illuminated when the light falls upon it at an angle. The proportion between the full rainfall or illumination and the measured rainfall or illumination varies as the cosine of the angle of incidence of the rain or of the light. This angle is 0deg. and the cosine is 1 when the rain-gauge is placed horizontally or when the light falls perpendicularly upon the surface. It would perhaps be unnecessary to call attention to these very elementary matters were it not that difference between the photometry of illumination and the ordinary photometry of candle-power is often confused.

The lighting of streets and of buildings may be specified by the maximum and minimum illumination. The primary purpose of an illumination photometer is to measure the resulting illumination produced by any arrangement of lamps, irrespective of their number, their height, or of their candle-power. Illumination photometers containing sub-standards of light have been designed by Prof. Weber,† Prof. Mascart,‡ and others. One of us described an illumination photometer before the Royal Society in 1883.§ This consisted of a box blackened within. Over the end was stretched a Bunsen screen of paper, on the middle of which was a grease spot. At a distance of 12in. was another screen of drawing paper. The grease spot was so screened that no light fell upon it, except that which was reflected from the drawing-paper screen. At the end of the box opposite the Bunsen screen was an eyepiece, consisting of a plain tube, within the box a small incandescent lamp was fixed, and in order to make a measurement of the illumination of the drawing paper screen, the current through the lamp was varied through a rheostat until the grease spot was invisible. The readings were recorded in luces, a lux being suggested by one of us at the Paris Electrical Congress, 1889, as the name for the illumination due to a carcel lamp at one metre, and equivalent to a British standard candle at 1·058ft. The only defect of this photometer was the yellowish and reddish colour of the lamp when dimmed for low readings.

In 1884 we designed a portable photometer,‖ in which the lamp could be moved towards or withdrawn from the Bunsen screen, and a mechanism was provided by which, when a pointer moved a certain distance over a uniformly divided scale, the displacement of the lamp was as the square of that distance. The Bunsen spot was viewed by Rudorff mirrors in the usual way. This instrument worked well, but the range was small, and could not be easily increased. The lamp would have to be moved to a very considerable distance from the screen for measuring the feeble illuminations met with in street-lighting.

Eight years later, one of us experimented with modifications of this instrument, and found that in ordinary street-lighting the illumination is often only equal to that due to one candle at 14ft. distance. A large number of different methods of reducing the light were tried. Many combinations of lenses, the eclipsing device used in dissolving views, photographically shaded glass screens, and other devices were used, and, finally, a white reflecting screen was inclined at different angles to a small electric lamp, and on this principle a photometer was constructed in February, 1892. It was found that the Bunsen screen could be replaced with advantage by a simple white cardboard diaphragm pierced with one or more holes.* The illumination of this diaphragm, generally in a horizontal position, was the illumination to be measured. Below this was the reflecting screen, enclosed in a box about 2ft. × 6in. × 5in., with a pair of small glow lamps and a secondary battery. The screen could be inclined towards the glow lamps by means of a chain wound up on a cam mounted on a spindle, the cam being formed so as to give an open scale. A hand, or pointer, indicated readings on a dial. Many measurements and a number of photometrical surveys of different streets and public buildings in London were made in 1892, and are recorded by means of plans with isophotal contour lines and otherwise.†

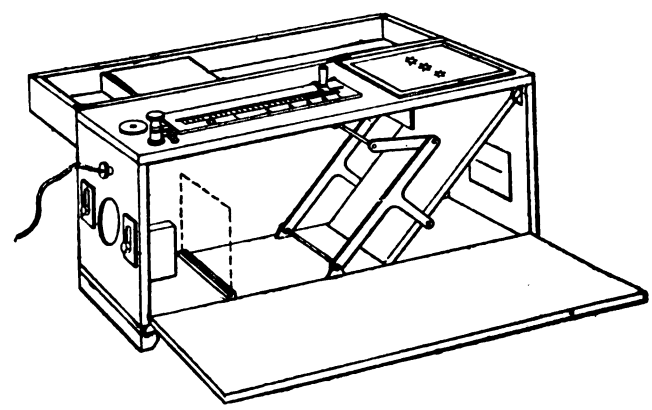

FIG. 1.

During the present year an improved form of this photometer has been constructed. The chain and cam, which allowed the instrument to be used only in a horizontal position, have been replaced by a system of levers. The object of these levers is to give an open scale. If the motion of the pointer were proportional to the angular movement of the screen, the scale would be approximately a scale of cosines. The instrument is shown in Fig. 1 with the lid open and the front let down. It measures 1ft. 3½in. by 5½in. by 9½in. high (400mm. × 140mm. × 242mm.). On the end to the left there is a red glass window, and immediately within are two 12-volt lamps (one of which is shown in Fig. 2), one of about 1 c.p., and the other of 2 c.p. It can be seen through the window if either or both of the lamps are alight. The lamps are held in special lamp-holders, capable of adjustment as to height by clamping screws. These clamping screws and the base of one of the lamp-holders are shown in Fig. 1. A switch on the top of the instrument enables either or both of the lamps to be turned on or off. At the other end of the box the reflecting screen is hung. The middle of the screen is about 11in. (28cm.) from the lamps. It is shown in Fig. 1 in its lowest position. In Fig. 2 the screen and one of the levers, together with one of the rollers on which the screen

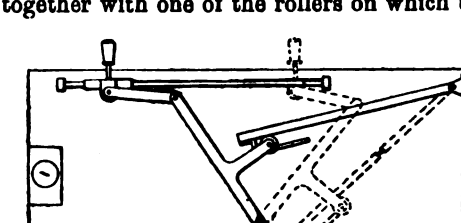

FIG. 2.

rests, and the handle by which it is moved, are shown with the screen in its highest position by full lines, and in its lowest position by dotted lines. In its highest position the filaments of the lamps are a little below the plane of the screen, no direct light from the lamps then reaches the screen, and is only faintly illuminated to about $\frac{1}{200}$th of one candle at a foot, by stray light, which is excluded as much as possible.

The diaphragm is placed horizontally immediately above the hinged screen. Three small star-shaped holes are cut in and through them; the illuminating reflecting screen can be seen. A handle carrying a pointer, moving over a graduated scale, controls the inclination of the screen by means of the levers and links. A guide attached to the back of the screen

(shown in Fig. 2) allows the instrument to be turned on its side without interfering with the working. In order to take a measurement, one or both of the lamps are turned on, and the handle is moved until the screen seen through the holes in the diaphragm matches the diaphragm in brightness. If the colour of the light outside is about the same as that of the lamps, the middle hole may be made to disappear. The observer should stand approximately in the vertical plane passing through the three holes, so that he may see that part of the screen through them which lies immediately beneath them.

Various substances have been tried for the diaphragm and screen. Thin metal painted with a whitewash made of magnesia and isinglass is perhaps the best. The diffused reflection practically follows Lambert's cosine law, but the material is easily soiled and cannot be cleaned. Bristol board, from which the glaze has been removed by a damp cloth, closely follows the cosine law within the angular range required in this case. It is important that there should be no glaze on the surface of the hinged screen, since the inclination of the lamp to the screen, and of the screen to the eye for maximum illumination, is about 45deg. But as the scale is graduated by experiment, a slight departure from the cosine law does not matter. On the other hand, it is of greater importance that the screen should be very smooth and flat. Under very feeble illuminations the light from the small lamp, making an angle of incidence very nearly 90deg., minute irregularities are easily seen, and make accurate readings difficult. For ordinary street-lighting and for general industrial photometry, a slight departure from the cosine law on the part of the diaphragm is of no practical consequence, so long as there is no perceptible glaze, for it is always observed nearly vertically and never at a large angle.

The colour difficulty is reduced, in the first instance, by the freedom of motion of the levers. The handle may be quickly moved to and fro on each side of the true reading, and the middle position may be estimated. In measuring the illumination due to arc lamps, the colour difficulty becomes troublesome. The colour of the incandescent lamp in the photometer should be approximately a mean between the colour of the standard of light wherewith the instrument is calibrated, and that of an arc lamp. This halves the difficulty which can never be entirely removed, since differently-coloured lights are not physically comparable. It may, however, be relegated entirely to the laboratory by the use of a coloured screen and diaphragm.

If the hinged screen be tinted pale blue, some of the yellow rays of the lamp in the photometer are absorbed, and the reflected rays approximate to grey—that is, to feebly illuminated white. On the other hand, if the diaphragm is tinted yellow, the white light from electric arcs or of daylight may be reduced to approximately the same colour as that of the lamp in the photometer. In the first case the brilliance of the hinged screen is reduced, and a brighter lamp would have to be used to restore the true value of the scale readings; and in the second case the brilliance of the diaphragm would be reduced, and the scale readings would be too high; but by tinting both screens the calibration of the instrument need not be disturbed. The screen being coloured pale blue and the diaphragm pale yellow there is no difficulty in obtaining disappearance of the hole in the diaphragm when illuminated by arc light or even by daylight. The selection of the colours suitable for obtaining a true measurement is based upon the mean of a number of measurements. White screens are used, and the comparison should be made in a building illuminated with a number of arc lights. A number of measurements are made with quick oscillations of the handle, and the mean is taken. Several screens and diaphragms of different tints being in readiness, pairs are tried, and a selection is made of a pair which give a good colour match,* and, if possible, the mean reading given by the white screens. A slight departure from the mean could be corrected by the use of a coefficient. It is not suggested that strongly-coloured lights can be scientifically compared in this manner, but only that the yellowish light of an incandescent lamp may be compared with the whitish light of an arc or of subdued daylight. We employed this device in 1884, and Messrs. G. W. and M. R. Patterson, the translators of Palaz's "Industrial Photometry," who have used it in connection with a Lummer-Brodhum photometer, remark* that "it can, of course, give no additional absolute accuracy to the photometric measurements; it, however, adds greatly to the comparative accuracy of the results, as it makes it possible to measure relative intensities under various conditions with great precision." But it should be observed that the selection of the tints may be made at leisure, and under favourable laboratory conditions, and by thus avoiding all colour trouble during ordinary use of the photometer, a very considerable gain in precision is secured.

FIG. 3.

The scale is 5½in. (137mm.) long, and is shown in Fig. 3. With the smaller of the two lamps the highest reading is equivalent to one candle at a foot, with the larger lamp it is twice this illumination. The oscillations of the handle generally extend at first over two scale divisions, and after three or four oscillations their amplitude may be reduced to about one scale division. The half of a scale division may be estimated except at the highest part of the scale, which is slightly contracted. The precision is about 2 or 3 per cent. The contraction of the upper part of the scale is intentional, and is caused by the arrangement of the levers.

In case of renewal of the lamps, it is very important that other lamps should be placed in exactly the same optical position in the photometer; otherwise the scale would have to be recalibrated. In order to fix the height of the lamps, which is the only adjustment necessary, a sheet-metal screen, shown by dotted lines in Fig. 1, is placed in a holder attached to the floor of the photometer. Two small holes are drilled in this screen, and a white paper screen having a black horizontal line is fastened to the end of the box (see Fig. 1) opposite to the lamps. The hinged screen being lifted by the levers out of the way, "pinhole images" of the filaments are thus thrown on to this screen, and the lamps being set (see Fig. 2) so that the single horseshoe filament appears nearly closed up, the dark line between its two limbs is made to fall on the black horizontal line. The images being magnified, considerable accuracy is possible.

Although the principal object of this photometer, as of those which preceded it, is the measurement of illumination, it is sometimes desirable to measure the candle-power of a lamp in the street without removing it from its position. By the use of a graduated arc, such measurements can be made with the present photometer. A quadrant is fastened to the side of the photometer, and a pin at the centre, from which the quadrant is struck, acts as a gnomon. A spirit-level on the top of the instrument being adjusted, the angle of incidence may be read in degrees on the quadrant, and at the same time the cosine of this angle may be read on an adjacent scale. It is necessary to find the slant height or direct distance from the source of light to the photometer.

To measure the vertical height of the light, set the photometer so that the shadow falls on 45deg. Measure the distance from the pin to the lamp horizontally, and from the pin to the ground vertically. The sum of these distances is the height of the actual source of light. This can be measured to about 2 per cent.—say, 3in. in 12ft. 6in. To find the slant height at any distance, the height of the light being known, divide the height of the lamp above the photometer by the cosine of the angle of incidence, the quotient is the slant height required; or the horizontal distance may be measured, and the square of this distance added to the square of the height of the light. This gives the square of the slant height. To find the candle-power, the illumination in units of a candle at a foot being observed, the light from other lamps being carefully screened, the slant height being known. Multiply the

* Owing to the Purkinge effect, an exact colour match cannot be maintained throughout the whole range. The holes in the diaphragm look yellowish under strong illumination, and bluish under feeble illumination.

* "A Treatise on Photometry," Palaz, American translation, Appendix, p. 312.

Digitized by Google

illumination by the square of the slant height, and divide by the cosine of the angle of incidence.

On hilly ground it is necessary to know the height of the lamp above the photometer at each point of measurement. It is best, in that case, merely to record the angles, and afterwards to find the tangents. The horizontal distance between the photometer and the lamp-post, divided by the tangent, gives the required height.

It may be observed that when the square of the slant height in feet is equal to the cosine of the angle of incidence, the scale graduated in units of a candle at a foot becomes a scale of candle-power, and when the square of the distance in feet is 10, 100, or 1,000 times the cosine, the multipliers 10, 100, or 1,000 may be used to convert it into a scale of candle-power. The square of the slant height being known, the photometer may be tilted until the required cosine is indicated by the shadow of the pin. If the slant height is measured by the sum of the squares of the horizontal distance and of the height, the square is at once obtained.

We have calibrated our photometers, either by standard candles or by sub-standard incandescent lamps supplied from secondary batteries, or by the amyl-acetate standard lamp or Hefner unit. This standard, which is well recognised in physical work, is 0·877 of a standard cable, or a standard candle is 14 per cent. more than an amyl-acetate lamp. Placed at 1ft. distance from, and perpendicular to, the diaphragm, the photometer being placed on its side, the illumination is 0·877 of a candle at a foot. If it is brought to a distance of 11¼in. ($\sqrt{0{\cdot}877}$ft.), it is equivalent to one candle at a foot. But this distance and position is inconvenient. If it is placed at a distance of 1ft., and at an angle of incidence of 55° 10′, the illumination on the diaphragm is one-half of a candle at a foot, since cos 55° 10′ = ·57 and ·57 × ·877 = 5. A mark is therefore made at this angle on the quadrant, and is inscribed H.U. = ½ c.p. Considerable experience with the use of small incandescent lamps supplied from portable secondary batteries has given us great confidence in this kind of secondary standard of candle-power. The battery is always freshly charged before each evening's work, and is discharged for half an hour before use. The lamps are only turned while an observation is being taken.

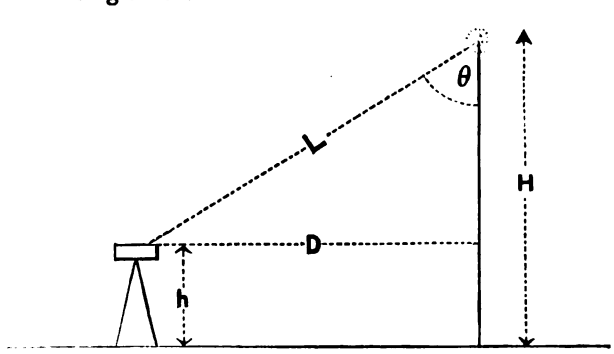

FIG. 4.

The 1883 photometer was arranged to be held in the hand; our 1884 photometer stood on a tripod about 2ft. 6in. from the ground. The street measurements made in 1892 were all made with a photometer placed on the ground, the diaphragm being about 6in. from the pavement. The proper height for an illumination photometer is a matter of opinion. When the photometer is placed on the ground, the large number of measurements required for a thorough photometric survey of a street or empty building can be quickly made. For some purposes—for example, an exhibition or a church—a stand is necessary; the calculations of candle-power become rather more tedious.

The various observed and computed quantities may be expressed as follows (see Fig. 4):

D = horizontal distance from photometer to lamp-post;
L = slant height from photometer to light;
H = height of light above the ground;
h = height of the photometer diaphragm from the ground;
θ = angle of incidence;
cf^2 = illumination of units of a candle at a foot;
$c.p.$ = candle-power.

$$H - h = D \div \tan \theta.$$

$$L = (H - h) \div \cos \theta.$$

$$= \sqrt{D^2 + (H - h)^2}.$$

$$c.p. = \frac{cf^2 + L^2.}{\cos \theta.}$$

The following is an example of the measurement of the illumination and candle-power in the case of a street lamp:

D	θ	cf^2	tan θ	cos θ	H − h	H	L	L^2	$cf^2 \times \cos \theta$	$c.p.$
20	66°	0·025	2 25	0·407	8·9	11·9	21·8	475	0 0614	29

NOTES ON THE LOCAL ORIGIN OF THE AURORA BOREALIS.*

BY W. H. WOOD.

The author found that calculations based on the cosmical theory of the aurora borealis gave results inconsistent with the facts of observation by placing the objects at such great distances from the observers as to preclude the light from reaching them. Also he found that the streamers do not show any variation in angular amplitude, nor in the intensity of the light at the various observing stations however distant or near to the assumed region of verticality, but the objects, on the contrary, present the same appearance as to distance from each and all those places. It is often objected against these facts that the observations are not carried out scientifically. It can be shown, however, that a display of aurora borealis is formed in a number of centres over a given tract of country. The various auroral figures constitute local groups having many features in common, but which can be differentiated, and their identity disestablished by the presence of a physical order of differences permeating the group and by the variable factors. A comparison of the radiant points of the streamers obtained from a set of observations, will show a remarkable difference in the amount and in the direction of the inclination of the streamers at each place of observation, proving the distinct group. Again, the time of maximum phase has been observed to travel across England from the east coast to the coast of Ireland in 2½ hours, the earliest phase commencing at the east coast and falling 10 minutes later in a series of successive stages across the country. The time of maximum phase at one place has been found to coincide with the time of minimum phase at another, maximum being defined as the period of the greatest number of auroral figures in sight, and the minimum phase marking a period of their absence. An ocular proof of the above was stated as follows: An auroral object visible in Manchester failed to be simultaneously seen at Birmingham, and also could not be seen 5½ miles north of Birmingham. The streamers also vanish under telescopic view, indicating dispersed points of light near at hand. Clouds and rain usually follow displays of the aurora, as reported from all stations. This the author considers due to electrical discharges. As an experiment in support of this, if a column of steam has its shadow cast on a whitewashed wall, and a current of electricity is passed through the steam, the shadow will be noticed to deepen and assume an orange-brown colour. This change is due to the coalescence of the minute particles of the water in the vapour. This is analogous to the change effected in the rain-clouds region by the aurora. Spectroscopic examination of the aurora shows indices of oxy-hydrocarbonic acid gas and argon corresponding to an electrical condition of moist air.

The author concludes that the plane of illumination is at right angles to the direction of the horizontal current, the plane being illuminated on the south side only in these northern latitudes.

PRESIDENTIAL ADDRESS TO THE BRITISH ASSOCIATION.

BY SIR DOUGLAS GALTON, K.C.B., D.C.L., F.R.S.

(Concluded from page 289.)

Physics.—If we turn to the sciences which are included under physics, the progress has been equally marked. In optical science, in 1831, the theory of emission as contrasted with the undulatory theory of light was still under discussion. Young, who was the first to explain the phenomena due to the interference of the rays of light as a consequence of the theory of waves, and Fresnel, who showed the intensity of light for any relative position of the interference waves, both had only recently passed away. The investigations into the laws which regulate the conduction and radiation of heat, together with the doctrine of latent and of specific heat, and the relations of vapour to air, had all tended to the conception of a material heat, or caloric, communicated by an actual flow and emission. It was not till 1834 that improved thermometrical appliances had enabled Forbes and Melloni to establish the polarisation of heat, and thus to lay the foundation of an undulatory theory for heat similar to that which was in progress of acceptation for light. Whewell's report, in 1832, on magnetism and electricity shows that these branches of science were looked upon as cognate, and that the theory of two opposite electric fluids was generally accepted. In magnetism, the investigations of Hansteen, Gauss, and Weber in Europe, and the observations made under the Imperial Academy of Russia over the vast extent of that empire, had established the existence of magnetic poles, and had shown that magnetic disturbances were simultaneous at all the stations of observation. At their third meeting the association urged the Government to establish magnetic and meteorological observatories in Great Britain and her colonies and dependencies in different parts of the earth, furnished with proper instruments, constructed on uniform principles, and with provisions for continued observations at those places. In 1839 the British Association had a large share in inducing the Government to initiate the valuable series of experiments for determining the intensity, the declination, the dip, and the periodical variations of the magnetic needle which were carried on for several years, at numerous selected stations over the surface of the globe, under the directions of Sabine and Lefroy.

In England systematic and regular observations are still made at Greenwich, Kew, and Stonyhurst. For some years past similar observations by both absolute and self-recording instruments have also been made at Falmouth—close to the home of Robert Were Fox, whose name is inseparably connected with the early history of terrestrial magnetism in this country—but under such great financial difficulties that the continuance of the work is seriously jeopardised. It is to be hoped that means may be forthcoming to carry it on. Cornishmen, indeed, could found no more fitting memorial of their distinguished countryman, John Couch Adams, than by suitably endowing the magnetic observatory in which he took so lively an interest. Far more extended observation will be needed before we can hope to have an established theory as to the magnetism of the earth. We are without magnetic observations over a large part of the southern hemisphere. And Prof. Rücker's recent investigations tell us that the earth seems, as it were alive, with magnetic forces, be they due to electric currents or to variations in the state of magnetised matter; that the disturbances affect not only the diurnal movement of the magnet, but that even the small part of the secular change which has been observed, and which has taken centuries to accomplish, is interfered with by some slower agency. And, what is more important, he tells us that none of these observations stand as yet upon a firm basis, because standard instruments have not been in accord; and much labour, beyond the power of individual effort, has hitherto been required to ascertain whether the relations between them are constant or variable.

In electricity, in 1831, just at the time when the British Association was founded, Faraday's splendid researches in electricity and magnetism at the Royal Institution had begun with his discovery of magneto-electric induction, his investigation of the laws of electro-chemical decomposition, and of the mode of electrolytical action. But the practical application of our electrical knowledge was then limited to the use of lightning-conductors for buildings and ships. Indeed, it may be said that the applications of electricity to the use of man have grown up side by side with the British Association. One of the first practical applications of Faraday's discoveries was in the deposition of metals and electroplating, which has developed into a large branch of national industry, and the dissociating effect of the electric arc for the reduction of ores, and in other processes, is daily obtaining a wider extension. But probably the application of electricity which is tending to produce the greatest change in our mental, and even material condition, is the electric telegraph and its sister, the telephone. By their agency not only do we learn, almost at the time of their occurrence, the events which are happening in distant parts of the world, but they are establishing a community of thought and feeling between all the nations of the world which is influencing their attitude towards each other, and, we may hope, may tend to weld them more and more into one family. The electric telegraph was introduced experimentally in Germany in 1833, two years after the formation of the association. It was made a commercial success by Cooke and Wheatstone in England, whose first attempts at telegraphy were made on the line from Euston to Camden Town in 1837, and on the line from Paddington to West Drayton in 1838. The submarine telegraph to America, conceived in 1856, became a practical reality in 1861 through the commercial energy of Cyrus Field and Pender, aided by the mechanical skill of Latimer Clark, Gooch, and others, and the scientific genius of Lord Kelvin. The knowledge of electricity gained by means of its application to the telegraph largely assisted the extension of its utility in other directions. The electric light gives, in its incandescent form, a very perfect hygienic light. Where rivers are at hand the electrical transmission of power will drive railway trains and factories economically, and might enable each artisan to convert his room into a workshop, and thus assist in restoring to the labouring man some of the individuality which the factory has tended to destroy. In 1843 Joule described his experiments for determining the mechanical equivalent of heat. But it was not until the meeting at Oxford, in 1847, that he fully developed the law of the conservation of energy, which, in conjunction with Newton's law of the conservation of momentum, and Dalton's law of the conservation of chemical elements, constitutes a complete mechanical foundation for physical science.

Who, at the foundation of the association, would have believed some far-seeing philosopher if he had foretold that the spectroscope would analyse the constituents of the sun and measure the motions of the stars; that we should liquefy air and utilise temperatures approaching to the absolute zero for experimental research; that, like the magician in the "Arabian Nights," we should annihilate distance by means of the electric telegraph and the telephone; that we should illuminate our largest buildings instantaneously, with the clearness of day, by means of the electric current; that by the electric transmission of power we should be able to utilise the Falls of Niagara to work factories at distant places; that we should extract metals from the crust of the earth by the same electrical agency to which, in some cases, their deposition has been attributed? These discoveries and their applications have been brought to their present condition by the researches of a long line of scientific explorers, such as Dalton, Joule, Maxwell, Helmholtz, Hertz, Kelvin, and Rayleigh, aided by vast strides made in mechanical skill. But what will our successors be discussing 60 years hence? How little do we yet know of the vibrations which communicate light and heat! Far as we have advanced in the application of electricity to the uses of life, we know but little even yet of its real nature. We are only on the threshold of the knowledge of molecular action, or of the constitution of the all-pervading ether. Newton at the end of the seventeenth century, in his preface to the "Principia," says: "I have deduced the motions of the planets by mathematical reasoning from forces, and I would that we could derive the other phenomena of nature from mechanical principles by the same mode of reasoning. For many things move me, so that I somewhat suspect that all such may depend on certain forces by which the particles of bodies through causes not yet known are either urged towards each other according to regular figures, or are repelled and recede from each other, and these forces being unknown philosophers have hitherto made their attempts on Nature in vain. In 1848 Faraday remarked: 'How rapidly the knowledge of molecular forces grows upon us, and how strikingly every investigation tends to develop more and more their importance! A few years ago magnetism was an occult force, affecting only a few bodies; now it is found to influence all bodies, and to possess the most intimate relation with electricity, heat, chemical action, light, crystallisation, and through it the forces concerned in cohesion. We may feel encouraged to continuous labours, hoping to bring it into a bond of union with gravity itself." But it is only within the last few years that we have begun to realise that electricity is closely connected with the vibrations which cause heat and light, and which seem to pervade all space—vibrations which may be termed the voice of the Creator calling to each atom and to each cell of protoplasm to fall into its ordained position, each, as it were, a musical note in the harmonious symphony which we call the universe.

Meteorology.—At the first meeting, in 1831, Prof. James D. Forbes was requested to draw up a report on the state of meteorological science, on the ground that this science is more in want than any other of that systematic direction which it is one great object of the association to give. Prof. Forbes made his first report in 1832, and a subsequent report in 1840. The systematic records now kept in various parts of the world of barometric pressure, of solar heat, of the temperature and physical conditions of the atmosphere at various altitudes, of the heat of the ground at various depths, of the rainfall, of the

Digitized by Google

prevalence of winds, and the gradual elucidation not only of the laws which regulate the movements of cyclones and storms, but of the influences which are exercised by the sun and by electricity and magnetism, not only upon atmospheric conditions, but upon health and vitality, are gradually approximating meteorology to the position of an exact science. England took the lead in rainfall observations. Mr. G. J. Symons organised the British rainfall system in 1860 with 178 observers—a system which until 1876 received the help of the British Association. Now Mr. Symons himself conducts it, assisted by more than 3,000 observers, and these volunteers not only make the observations, but defray the expense of their reduction and publication. In foreign countries this work is done by Government officers at the public cost. At the present time a very large number of rain-gauges are in daily use throughout the world. The British Islands have more than 3,000, and India and the United States have nearly as many; France and Germany are not far behind; Australia probably has more—indeed, one colony alone, New South Wales, has more than 1,100. The storm warnings now issued under the excellent systematic organisation of the Meteorological Committee may be said to have had their origin in the terrible storm which broke over the Black Sea during the Crimean War, on November 27, 1855. Leverrier traced the progress of that storm, and seeing how its path could have been reported in advance by the electric telegraph, he proposed to establish observing stations which should report to the coasts the probability of the occurrence of a storm. Leverrier communicated with Airy, and the Government authorised Admiral FitzRoy to make tentative arrangements in this country. The idea was also adopted on the Continent, and now there are few civilised countries north or south of the equator without a system of storm warning.*

Biological Science.

Botany.—The earliest reports of the association which bear on the biological sciences were those relating to botany. In 1831 the controversy was yet unsettled between the advantages of the Linnean, or artificial system, as contrasted with the natural system of classification. Histology, morphology, and physiological botany, even if born, were in their early infancy. Our records show that von Mohl noted cell division in 1835, the presence of chlorophyll corpuscles in 1837, and he first described protoplasm in 1846. Vast as have been the advances of physiological botany since that time, much of its fundamental principles remain to be worked out, and I trust that the establishment, for the first time, of a permanent section for botany at the present meeting will lead the association to take a more prominent part than it has hitherto done in the further development of this branch of biological science.

Animal Physiology.—In 1831 Cuvier, who during the previous generation had, by the collation of facts followed by careful inductive reasoning, established the plan on which each animal is constructed, was approaching the termination of his long and useful life. He died in 1832; but in 1831 Richard Owen was just commencing his anatomical investigations and his brilliant contributions to palæontology. The impulse which their labours gave to biological science was reflected in numerous reports and communications, by Owen and others, throughout the early decades of the British Association, until Darwin propounded a theory of evolution which commanded the general assent of the scientific world. For this theory was not absolutely new. But just as Cuvier had shown that each bone in the fabric of an animal affords a clue to the shape and structure of the animal, so Darwin brought harmony into scattered facts, and led us to perceive that the moulding hand of the Creator may have evolved the complicated structures of the organic world from one or more primeval cells. Richard Owen did not accept Darwin's theory of evolution, and a large section of the public contested it. I well remember the storm it produced—a storm of praise by my geological colleagues, who accepted the result of investigated facts; a storm of indignation such as that which would have burned Galileo at the stake from those who were not yet prepared to question the old authorities; but they diminish daily. We are, however, as yet only on the threshold of the doctrine of evolution. Does not each fresh investigation, even into the embryonic stage of the simpler forms of life, suggest fresh problems?

Anthropology.—The impulse given by Darwin has been fruitful in leading others to consider whether the same principle of evolution may not have governed the moral as well as the material progress of the human race. Mr. Kidd tells us that Nature as interpreted by the struggle for life contains no sanction for the moral progress of the individual, and points out that if each of us were allowed by the conditions of life to follow his own inclination, the average of each generation would distinctly deteriorate from that of the preceding one; but because the law of life is ceaseless and inevitable struggle and competition, ceaseless and inevitable selection and rejection, the result is necessarily ceaseless and inevitable progress. Evolution, as Sir William Flower said, is the message which biology has sent to help us on with some of the problems of human life, and Francis Galton urges that man, the foremost outcome of the awful mystery of evolution, should realise that he has the power of shaping the course of future humanity by using his intelligence to discover and expedite the changes which are necessary to adapt circumstances to man, and man to circumstances. In considering the evolution of the human race, the science of preventive medicine may afford us some indication of the direction in which to seek for social improvement. One of the early steps towards establishing that science upon a secure basis was taken in 1835 by the British Association, who urged upon the Government the necessity of establishing registers of mortality showing the causes of death "on one uniform plan in all parts of the King's dominions, as the only means by which general laws touching the influence of causes of disease and death could be satisfactorily deduced." The general registration of births and deaths was commenced in 1838. But a mere record of death and its proximate cause is insufficient. Preventive medicine requires a knowledge of the details of the previous conditions of life and of occupation. Moreover, death is not our only or most dangerous enemy, and the main object of preventive medicine is to ward off disease. Disease of body lowers our useful energy. Disease of body or of mind may stamp its curse on succeeding generations. The anthropometric laboratory affords to the student of anthropology a means of analysing the causes of weakness, not only in bodily, but also in mental life. Mental actions are indicated by movements and their results. Such signs are capable of record, and modern physiology has shown that bodily movements correspond to action in nerve centres as surely as the motions of the telegraph indicator express the movements of the operator's hands in the distant office. Thus there is a relation between a defective status in brain power and defects in the proportioning of the body. Defects in physiognomical details, too finely graded to be measured with instruments, may be appreciated with accuracy by the senses of the observer, and the records show that these defects are, in a large degree, associated with a brain status lower than the average in mental power. A report presented by one of your committees gives the results of observations made on 100,000 school-children examined individually in order to determine their mental and physical condition for the purpose of classification. This shows that about 16 per 1,000 of the elementary school population appear to be so far defective in their bodily or brain condition as to need special training to enable them to undertake the duties of life, and to keep them from pauperism or crime. Many of our feeble-minded children, and much disease and vice, are the outcome of inherited proclivities. Francis Galton has shown us that types of criminals which have been bred true to their kind are one of the saddest disfigurements of modern civilisation; and he says that few deserve better of their country than those who determine to lead celibate lives through a reasonable conviction that their issue would probably be less fitted than the generality to play their part as citizens. These considerations point to the importance of preventing those suffering from transmissible disease, or the criminal, or the lunatic, from adding fresh sufferers to the teeming misery in our large towns. And in any case, knowing as we do the influence of environment on the development of individuals, they point to the necessity of removing those who are born with feeble minds, or under conditions of moral danger, from surrounding deteriorating influences. These are problems which materially affect the progress of the human race, and we may feel sure that, as we gradually approach their solution, we shall more certainly realise that the theory of evolution, which the genius of Darwin impressed on this century, is but the first step on a biological ladder which may possibly eventually lead us to understand how in the drama of creation man has been evolved as the highest work of the Creator.

Bacteriology.—The sciences of medicine and surgery were largely represented in the earlier meetings of the association before the creation of the British Medical Association afforded a field for their more intimate discussion. The close connection between the different branches of science is causing a revival in our proceedings of discussions on some of the highest medical problems, especially those relating to the spread of infectious and epidemic disease. It is interesting to contrast the opinion prevalent at the foundation of the association with the present position of the question. A report to the association in 1834 by Prof. Henry on contagion says: "The notion that contagious emanations are at all connected with the diffusion of animalculæ through the atmosphere is at variance with all that is known of the diffusion of volatile contagion." Whilst it had long been known that filthy conditions in air, earth, and water fostered fever, cholera, and many other forms of disease, and that the disease ceased to spread on the removal of these conditions, yet the reason for their propagation or

* It has often been supposed that Leverrier was also the first to issue a daily weather map, but that was not the case, for in the Great Exhibition of 1851 the Electric Telegraph Company sold daily weather maps, copies of which are still in existence, and the data for them were, it is believed, obtained by Mr. James Glaisher, F.R.S., at that time superintendent of the Meteorological Department at Greenwich.

Digitized by Google

diminution remained under a veil. Leeuwenhoeck in 1680 described the yeast cells, but Schwann in 1837 first showed clearly that fermentation was due to the activity of the yeast cells; and, although vague ideas of fermentation had been current during the past century, he laid the foundation of our exact knowledge of the nature of the action of ferments, both organised and unorganised. It was not until 1860, after the prize of the Academy of Sciences had been awarded to Pasteur for his essay against the theory of spontaneous generation, that his investigations into the action of ferments* enabled him to show that the effects of the yeast cell are indissolubly bound up with the activities of the cell as a living organism, and that certain diseases, at least, are due to the action of ferments in the living being. In 1865 he showed that the disease of silk-worms, which was then undermining the silk industry in France, could be successfully combated. His further researches into anthrax, fowl cholera, swine fever, rabies, and other diseases proved the theory that those diseases are connected in some way with the introduction of a microbe into the body of an animal; that the virulence of the poison can be diminished by cultivating the microbes in an appropriate manner; and that when the virulence has been thus diminished their inoculation will afford a protection against the disease. Meanwhile it had often been observed in hospital practice that a patient with a simple-fractured limb was easily cured, whilst a patient with a compound fracture often died from the wound. Lister was thence led, in 1865, to adopt his antiseptic treatment, by which the wound is protected from hostile microbes. These investigations, followed by the discovery of the existence of a multitude of micro-organisms and the recognition of some of them—such as the bacillus of tubercle and the comma bacillus of cholera—as essential factors of disease; and by the elaboration by Koch and others of methods by which the several organisms might be isolated, cultivated, and their histories studied, have gradually built up the science of bacteriology. Amongst later developments are the discovery of various so-called antitoxins, such as those of diphtheria and tetanus, and the utilisation of these for the cure of disease. Lister's treatment formed a landmark in the science of surgery, and enabled our surgeons to perform operations never before dreamed of, whilst later discoveries are tending to place the practice of medicine on a firm scientific basis; and the science of bacteriology is leading us to recur to stringent rules for the isolation of infectious disease, and to the disinfection (by superheated steam) of materials which have been in contact with the sufferer. These microbes, whether friendly or hostile, are all capable of multiplying at an enormous rate under favourable conditions. They are found in the air, in water, in the soil; but, fortunately, the presence of one species appears to be detrimental to other species, and sunshine, or even light from the sky, is prejudicial to most of them. Our bodies, when in health, appear to be furnished with special means of resisting attacks, and so far as regards their influence in causing disease the success of the attack of a pathogenic organism upon an individual depends, as a rule, in part at least, upon the power of resistance of the individual. But notwithstanding our knowledge of the danger arising from a state of low health in individuals, and of the universal prevalence of these micro-organisms, how careless we are in guarding the health conditions of everyday life! We have ascertained that pathogenic organisms prevade the air. Why, therefore, do we allow our meat, our fish, our vegetables, our easily contaminated milk, to be exposed to their inroads, often in the foulest localities? We have ascertained that they pervade the water we drink, yet we allow foul water from our dwellings, our pigsties, our farmyards, to pass into ditches without previous clarification, whence it flows into our streams and pollutes our rivers. We know the conditions of occupation which foster ill-health. Why, whilst we remove outside sources of impure air, do we permit the occupation of foul and unhealthy dwellings? The study of bacteriology has shown us that although some of these organisms may be the accompaniments of disease, yet we owe it to the operation of others that the refuse caused by the cessation of animal and vegetable life is reconverted into food for fresh generations of plant and animals. These considerations have formed a point of meeting where the biologist, the chemist, the physicist, and the statistician unite with the sanitary engineer in the application of the science of preventive medicine.

Engineering.

Sewage Purification.—The early reports of the association show that the laws of hydrostatics, hydrodynamics, and hydraulics necessary to the supply and removal of water through pipes and conduits had long been investigated by the mathematician. But the modern sanitary engineer has been driven by the needs of an increasing population to call in the chemist and the biologist to help him to provide pure water and pure air. The purification and the utilisation of sewage occupied the attention of the British Association as early as 1864, and between 1869 and 1876 a committee of the association made a series of valuable reports on the subject. The direct application of sewage to land, though effective as a means of purification, entailed difficulties in thickly-settled districts, owing to the extent of land required. The chemical treatment of sewage produced an effluent harmless only after having been passed over land, or if turned into a large and rapid stream, or into a tidal estuary, and it left behind a large amount of sludge to be dealt with. Hence it was long contended that the simplest plan in favourable localities was to turn the sewage into the sea, and that the consequent loss to the land of the manurial value in the sewage would be recouped by the increase in fish life. It was not till the chemist called to his aid the biologist, and came to the help of the engineer, that a scientific system of sewage purification was evolved. Dr. Frankland many years ago suggested the intermittent filtration of sewage, and Mr. Baldwin Latham was one of the first engineers to adopt it. But the valuable experiments made in recent years by the State Board of Health in Massachusetts have more clearly explained to us how by this system we may utilise micro-organisms to convert organic impurity in sewage into food fitted for higher forms of life. To effect this we require, in the first place, a filter about 5ft. thick of sand and gravel, or, indeed, of any material which affords numerous surfaces or open pores. Secondly, that after a volume of sewage has passed through the filter, an interval of time be allowed, in which the air necessary to support the life of the micro-organisms is enabled to enter the pores of the filter. Thus the system is dependent upon oxygen and time. Under such conditions the organisms necessary for purification are sure to establish themselves in the filter before it has been long in use. Temperature is a secondary consideration. Imperfect purification can invariably be traced either to a lack of oxygen in the pores of the filter, or to the sewage passing through so quickly that there is not sufficient time for the necessary processes to take place. And the power of any material to purify either sewage or water depends almost entirely upon its ability to hold a sufficient proportion of either sewage or water in contact with a proper amount of air.

Smoke Abatement.—Whilst the sanitary engineer has done much to improve the surface conditions of our towns, to furnish clean water, and to remove our sewage, he has as yet done little to purify town air. Fog is caused by the floating particles of matter in the air becoming weighted with aqueous vapour; some particles, such as salts of ammonia or chloride of sodium, have a greater affinity for moisture than others. You will suffer from fog so long as you keep refuse stored in your towns to furnish ammonia, or so long as you allow your street surfaces to supply dust, of which much consists of powdered horse manure, or so long as you send the products of combustion into the atmosphere. Therefore, when you have adopted mechanical traction for your vehicles in towns you may largely reduce one cause of fog; and if you diminish your black smoke, you will diminish black fogs. In manufactories you may prevent smoke either by care in firing, by using smokeless coal, or by washing the soot out of the products of consumption in its passage along the flue leading to the main chimney-shaft. The black smoke from your kitchen may be avoided by the use of coke or of gas. But so long as we retain the hygienic arrangement of the open fire in our living-rooms I despair of finding a fireplace, however well constructed, which will not be used in such a manner as to cause smoke, unless, indeed, the chimneys were reversed and the fumes drawn into some central shaft, where they might be washed before being passed into the atmosphere. Electricity as a warming and cooking agent would be convenient, cleanly, and economical when generated by water power, or possibly wind power, but it is at present too dear when it has to be generated by means of coal. I can conceive, however, that our descendants may learn so to utilise electricity that they, in some future century, may be enabled by its means to avoid the smoke in their towns.

Mechanical Engineering. — In other branches of civil and mechanical engineering, the reports in 1831 and 1832 on the state of this science show that the theoretical and practical knowledge of the strength of timber had obtained considerable development. But in 1830, before the introduction of railways, cast iron had been sparingly used in arched bridges for spans of from 160 to 200 feet, and wrought iron had only been applied to large-span iron bridges on the suspension principle, the most notable instance of which was the Menai Suspension Bridge, by Telford. Indeed, whilst the strength of timber had been patiently investigated by engineers, the best form for the use of iron girders and struts was only beginning to attract attention, and the earlier volumes of our *Proceedings* contained numerous records of the researches of Eaton Hodgkinson, Barlow, Rennie, and others. It was not until 20 years later that Robert Stephenson and William Fairbairn erected the tubular bridge at Menai, followed by the more scientific bridge erected by Brunel at Saltash. These have now been entirely

* In speaking of ferments one must bear in mind that there are two classes of ferments: one, living beings, such as yeast—"organised" ferments, as they are sometimes called; the other the products of living beings themselves, such as pepsin, etc.—"unorganised" ferments. Pasteur worked with the former, very little with the latter.

Digitized by Google

eclipsed by the skill with which the estuary of the Forth has been bridged with a span of 1,700ft. by Sir John Fowler and Sir Benjamin Baker. The development of the iron industry is due to the association of the chemist with the engineer. The introduction of the hot blast by Neilson, in 1829, in the manufacture of cast iron has effected a large saving of fuel. But the chemical conditions which affect the strength and other qualities of iron, and its combination with carbon, silicon, phosphorus, and other substances, had at that time scarcely been investigated. In 1856 Bessemer brought before the British Association at Cheltenham his brilliant discovery for making steel direct from the blast furnace, by which he dispensed with the laborious process of first removing the carbon from pig iron by puddling and then adding by cementation the required proportion of carbon to make steel. This discovery, followed by Siemens's regenerative furnace, by Whitworth's compressed steel, and by the use of alloys, and by other improvements too numerous to mention here, have revolutionised the conditions under which metals are applied to engineering purposes. Indeed, few questions are of greater interest, or possess more industrial importance, than those connected with metallic alloys. This is especially true of those alloys which contain the rarer metals, and the extraordinary effects of small quantities of chromium, nickel, tungsten, and titanium on certain varieties of steel have exerted profound influence on the manufacture of projectiles and on the construction of our armoured ships.

Of late years, investigations on the properties and structure of alloys have been numerous, and among the more noteworthy researches may be mentioned those of Dewar and Fleming on the distinctive behaviour, as regards the thermo-electric powers and electrical resistance, of metals and alloys at the very low temperatures which may be obtained by the use of liquid air. Prof. Roberts-Austen, on the other hand, has carefully studied the behaviour of alloys at very high temperatures, and by employing his delicate pyrometer has obtained photographic curves which afford additional evidence as to the existence of allotropic modifications of metals, and which have materially strengthened the view that alloys are closely analogous to saline solutions. In this connection it may be stated that the very accurate work of Heycock and Neville on the lowering of the solidifying points of molten metals, which is caused by the presence of other metals, affords a valuable contribution to our knowledge. Prof. Roberts-Austen has, moreover, shown that the effect of any one constituent of an alloy upon the properties of the principal metal has a direct relation to the atomic volumes, and that it is consequently possible to foretell, in a great measure, the effect of any given combination. A new branch of investigation, which deals with the micro-structure of metals and alloys, is rapidly assuming much importance. It was instituted by Sorby in a communication which he made to the British Association in 1864, and its development is due to many patient workers, among whom M. Osmond occupies a prominent place. Metallurgical science has brought aluminium into use by cheapening the process of its extraction ; and if by means of the wasted forces in our rivers, or possibly of the wind, the extraction be still further cheapened by the aid of electricity, we may not only utilise the metal or its alloys in increasing the spans of our bridges, and in affording strength and lightness in the construction of our ships, but we may hope to obtain a material which may render practicable the dreams of Icarus and of Maxim, and for purposes of rapid transit enable us to navigate the air.

Long before 1831 the steam-engine had been largely used on rivers and lakes, and for short sea passages, although the first Atlantic steam service was not established till 1838. As early as 1820 the steam-engine had been applied by Gurney, Hancock, and others to road traction. The absurd impediments placed in their way by road trustees, which, indeed, are still enforced, checked any progress. But the question of mechanical traction on ordinary roads was practically shelved in 1830, at the time of the formation of the British Association, when the locomotive engine was combined with a tubular boiler and an iron road on the Liverpool and Manchester Railway. Great, however, as was the advance made by the locomotive engine of Robert Stephenson, these earlier engines were only toys compared with the compound engines of to-day which are used for railways, for ships, or for the manufacture of electricity. Indeed, it may be said that the study of the laws of heat, which have led to the introduction of various forms of motive power, are gradually revolutionising all our habits of life. The improvements in the production of iron, combined with the developed steam-engine, have completely altered the conditions of our commercial intercourse on land ; whilst the changes caused by the effects of these improvements in shipbuilding, and on the ocean carrying trade, have been, if anything, still more marked. At the foundation of the association all ocean ships were built by hand, of wood, propelled by sails and manœuvred by manual labour ; the material limited their length, which did not often exceed 100ft., and the number of English ships of over 500 tons burden was comparatively small. In the modern ships steam power takes the place of manual labour. It rolls the plates of which the ship is constructed, bends them to the required shape, cuts, drills, and rivets them in their place. It weighs the anchor ; it propelled the ship in spite of winds or currents ; it steers, ventilates, and lights the ship when on the ocean. It takes the cargo on board and discharges it on arrival. The use of iron favours the construction of ships of a large size, of forms which afford small resistance to the water, and with compartments which make the ship practically unsinkable in heavy seas, or by collision. Their size, the economy with which they are propelled, and the certainty of their arrival, cheapens the cost of transport. The steam-engine, by compressing air, gives us control over the temperature of cool-chambers. In these not only fresh meat, but the delicate produce of the Antipodes, is brought across the ocean to our doors without deterioration. Whilst railways have done much to alter the social conditions of each individual nation, the application of iron and steam to our ships is revolutionising the international commercial conditions of the world ; and it is gradually changing the course of our agriculture, as well as of our domestic life.

But great as have been the developments of science in promoting the commerce of the world, science is asserting its supremacy even to a greater extent in every department of war. And perhaps this application of science affords at a glance, better than almost any other, a convenient illustration of the assistance which the chemical, physical, and electrical sciences are affording to the engineers. The reception of warlike stores is not now left to the uncertain judgment of "practical men," but is confided to officers who have received a special training in chemical analysis, and in the application of physical and electrical science to the test by which the qualities of explosives, of guns, and of projectiles can be ascertained. For instance, take explosives. Till quite recently black and brown powders alone were used, the former as old as civilisation, the latter but a small modern improvement adapted to the increased size of guns. But now the whole family of nitro-explosives are rapidly superseding the old powder. These are the direct outcome of chemical knowledge ; they are not mere chance inventions, for every improvement is based on chemical theories, and not on random experiment. The construction of guns is no longer a haphazard operation. In spite of the enormous forces to be controlled and the sudden violence of their action, the researches of the mathematician have enabled the just proportions to be determined with accuracy ; the labours of the physicist have revealed the internal conditions of the materials employed, and the best means of their favourable employment. Take, for example, Longridge's coiled-wire system, in which each successive layer of which the gun is formed receives the exact proportion of tension which enables all the layers to act in unison. The chemist has rendered it clear that even the smallest quantities of certain ingredients are of supreme importance in affecting the tenacity and trustworthiness of the materials. The treatment of steel to adapt it to the vast range of duties it has to perform is thus the outcome of patient research. And the use of the metals—manganese, chromium, nickel, molybdneum—as alloys with iron has resulted in the production of steels possessing varied and extraordinary properties. The steel required to resist the conjugate stresses developed, lightning fashion, in a gun necessitates qualities that would not be suitable in the projectile which that gun hurls with a velocity of some 2,500ft. per second against the armoured side of a ship. The armour, again, has to combine extreme superficial hardness with great toughness, and during the last few years these qualities are sought to be attained by the application of the cementation process for adding carbon to one face of the plate, and hardening that face alone by rapid refrigeration.

The introduction of quick-firing guns from ·303 (*i.e.*, about one-third) of an inch to 6in. calibre has rendered necessary the production of metal cartridge-cases of complex forms drawn cold out of solid blocks or plate of the material ; this, again, has taxed the ingenuity of the mechanic in the device of machinery, and of the metallurgist in producing a metal possessed of the necessary ductility and toughness. The cases have to stand a pressure at the moment of firing of as much as 25 tons to the square inch—a pressure which exceeds the ordinary elastic limits of the steel of which the gun itself is composed. There is nothing more wonderful in practical mechanics than the closing of the breech openings of guns, for not only must they be gas-tight at these tremendous pressures, but the mechanism must be such that one man by a single continuous movement shall be able to open or close the breech of the largest gun in some 10 or 15 seconds. The perfect knowledge of the recoil of guns has enabled the reaction of the discharge to be utilised in compressing air or springs by which guns can be raised from concealed positions in order to deliver their fire, and then made to disappear again for loading; or the same force has been used to run up the guns automatically immediately after firing, or, as in the case of the Maxim gun, to deliver in the same way a continuous stream of bullets at the rate of 10 in one second. In the manufacture of shot and shell cast iron has been almost superseded by cast and wrought steel, though the hardened Palliser projectiles still hold their place. The forged-steel projectiles are produced by methods very similar to those used in the manu-

Digitized by Google

facture of metal cartridge-cases, though the process is carried on at a red heat and by machines much more powerful.

In every department concerned in the production of warlike stores electricity is playing a more and more important part. It has enabled the passage of a shot to be followed from its seat in the gun to its destination. In the gun, by means of electrical contacts arranged in the bore, a time curve of the passage of the shot can be determined. From this the mathematician constructs the velocity curve, and from this, again, the pressures producing the velocity are estimated, and used to check the same indications obtained by other means. The velocity of the shot after it has left the gun is easily ascertained by the Boulangé apparatus. Electricity and photography have been laid under contribution for obtaining records of the flight of projectiles and the effects of explosions at the moment of their occurrence. Many of you will recollect Mr. Vernon Boys's marvellous photographs showing the progress of the shot driving before it waves of air in its course. Electricity and photography also record the properties of metals and their alloys as determined by curves of cooling. The readiness with which electrical energy can be converted into heat or light has been taken advantage of for the firing of guns, which in their turn can, by the same agency, be laid on the object by means of range-finders placed at a distance and in advantageous and safe positions; while the electric light is utilised to illumine the sights at night as well as to search out the objects of attack. The compact nature of the incandescent lamp, the brightness of the light, the circumstance that the light is not due to combustion and therefore independent of air, facilitates the examination of the bore of guns, the insides of shells, and other similar uses—just as it is used by a doctor to examine the throat of a patient.

Influence of Intercommunication afforded by British Association on Science Progress.

The advances in engineering which have produced the steam-engine, the railway, the telegraph, as well as our engines of war, may be said to be the result of commercial enterprise rendered possible only by the advances which have taken place in the several branches of science since 1831. Having regard to the intimate relations which the several sciences bear to each other, it is abundantly clear that much of this progress could not have taken place in the past, nor could further progress take place in the future, without intercommunication between the students of different branches of science. The founders of the British Association based its claims to utility upon the power it afforded for this intercommunication. Mr. Vernon-Harcourt (the uncle of your present general secretary), in the address he delivered in 1832, said: "How feeble is man for any purpose when he stands alone—how strong when united with other men! It may be true that the greatest philosophical works have been achieved in privacy, but it is no less true that these works would never have been accomplished had the authors not mingled with men of corresponding pursuits, and from the commerce of ideas often gathered germs of apparently insulated discoveries, and without such material aid would seldom have carried their investigations to a valuable conclusion." I claim for the British Association that it has fulfilled the object of its founders, that it has had a large share in promoting intercommunication and combination. Our meetings have been successful because they have maintained the true principles of scientific investigation. We have been able to secure the continued presence and concurrence of the master-spirits of science. They have been willing to sacrifice their leisure, and to promote the welfare of the association, because the meetings have afforded them the means of advancing the sciences to which they are attached. The association has, moreover, justified the views of its founders in promoting intercourse between the pursuers of science, both at home and abroad, in a manner which is afforded by no other agency. The weekly and sessional reunions of the Royal Society and the annual soirées of other scientific societies promote this intercourse to some extent, but the British Association presents to the young student during its week of meetings easy and continuous social opportunities for making the acquaintance of leaders in science, and thereby obtaining their directing influence. It thus encourages, in the first place, opportunities of combination, but, what is equally important, it gives at the same time material assistance to the investigators whom it thus brings together. The reports on the state of science at the present time, as they appear in the last volume of our *Proceedings*, occupy the same important position, as records of science progress, as that occupied by those reports in our earlier years. We exhibit no symptom of decay.

Science in Germany fostered by the State and Municipalities.

Our neighbours and rivals rely largely upon the guidance of the State for the promotion of both science teaching and of research. In Germany the foundations of technical and industrial training are laid in the Realschulen, and supplemented by the higher technical schools. In Berlin that splendid institution, the Royal Technical High School, casts into the shade the facilities for education in the various polytechnics which we are now establishing in London. Moreover, it assists the practical workman by a branch department, which is available to the public for testing building materials, metals, paper, oil, and other matters. The standards of all weights and measures used in trade can be purchased from or tested by the Government Department for Weights and Measures. For developing pure scientific research and for promoting new applications of science to industrial purposes the German Government, at the instance of von Helmholtz, and aided by the munificence of Werner von Siemens, created the Physikalische Technische Reichsanstalt at Charlottenburg. This establishment consists of two divisions. The first is charged with pure research, and is at the present time engaged in various thermal, optical, and electrical and other physical investigations. The second branch is employed in operations of delicate standardising to assist the wants of research students—for instance, dilatation, electrical resistances, electric and other forms of light, pressure gauges, recording instruments, thermometers, pyrometers, tuning-forks, glass, oil-testing apparatus, viscosity of glycerine, etc. Dr. Kohlrausch succeeded Helmholtz as president, and takes charge of the first division. Prof. Hagen, the director under him, has charge of the second division. A professor is in charge of each of the several sub-departments. Under these are various subordinate posts, held by younger men, selected for previous valuable work, and usually for a limited time. The general supervision is under a council, consisting of a president, who is a privy councillor, and 24 members, including the president and director of the Reichsanstalt; of the other members, about 10 are professors or heads of physical and astronomical observatories connected with the principal universities in Germany. Three are selected from leading firms in Germany representing mechanical, optical, and electric science, and the remainder are principal scientific officials connected with the Departments of War and Marine, the Royal Observatory at Potsdam, and the Royal Commission for Weights and Measures. This council meets in the winter, for such time as may be necessary, for examining the research work done in the first division during the previous year, and for laying down the scheme for research for the ensuing year; as well as for suggesting any requisite improvements in the second division. As a consequence of the position which science occupies in connection with the State in Continental countries, the services of those who have distinguished themselves either in the advancement or in the application of science are recognised by the award of honours; and thus the feeling for science is encouraged throughout the nation.

Assistance to Scientific Research in Great Britain.

Great Britain maintained for a long time a leading position among the nations of the world by virtue of the excellence and accuracy of its workmanship, the result of individual energy; but the progress of mechanical science has made accuracy of workmanship the common property of all nations of the world. Our record shows that hitherto, in its efforts to maintain its position by the application of science and the prosecution of research, England has made marvellous advances by means of voluntary effort, illustrated by the splendid munificence of such men as Gassiot, Joseph Whitworth, James Mason, and Ludwig Mond; and, whilst the increasing field of scientific research compels us occasionally to seek for Government assistance, it would be unfortunate if by any change voluntary effort were fettered by State control.

The following are the principal voluntary agencies which help forward scientific research in this country: the Donation Fund of the Royal Society, derived from its surplus income. The British Association has contributed £60,000 to aid research since its formation. The Royal Institution, founded in the last century, by Count Rumford, for the promotion of research, has assisted the investigations of Davy, of Young, of Faraday, of Frankland, of Tyndall, of Dewar, and of Rayleigh. The City companies assist scientific research and foster scientific education both by direct contributions and through the City and Guilds Institute. The Commissioners of the Exhibition of 1851 devote £6,000 annually to science research scholarships, to enable students who have passed through a college curriculum and have given evidence of capacity for original research to continue the prosecution of science, with a view to its advance or to its application to the industries of the country. Several scientific societies, as, for instance, the Geographical Society and the Mechanical Engineers, have promoted direct research, each in their own branch of science, out of their surplus income; and every scientific society largely assist research by the publication, not only of its own proceedings, but often of the work going on abroad in the branch of science which it represents. The growing abundance of matter year by year increase the burden thus thrown on their finances, and the Treasury has recently granted to the Royal Society £1,000 a year, to be spent in aid of the publication of scientific papers not necessarily limited to those of that society. The Royal Society has long felt the importance to scientific research of a catalogue of all papers and publications relating to pure and applied science, arranged systematically both as to authors' names and as to

Digitized by Google

subject treated, and the society has been engaged for some time upon a catalogue of that nature. But the daily increasing magnitude of these publications, coupled with the necessity of issuing the catalogue with adequate promptitude, and at appropriate intervals, renders it a task which could only be performed under international co-operation. The officers of the Royal Society have therefore appealed to the Government to urge foreign Governments to send delegates to a conference to be held next July to discuss the desirability and the scope of such a catalogue, and the possibility of preparing it.

The universities and colleges distributed over the country, besides their function of teaching, are large promoters of research, and their voluntary exertions are aided in some cases by contributions from Parliament in alleviation of their expenses. Certain executive departments of the Government carry on research for their own purposes, which in that respect may be classed as voluntary. The Admiralty maintains the Greenwich Observatory, the Hydrographical Department, and various experimental services; and the War Office maintains its numerous scientific departments. The Treasury maintains a valuable chemical laboratory for Inland Revenue, Customs, and agricultural purposes. The Science and Art Department maintains the Royal College of Science, for the education of teachers and students from elementary schools. It allows the scientific apparatus in the national museum to be used for research purposes by the professors. The Solar Physics Committee, which has carried on numerous researches in solar physics, was appointed by and is responsible to this department. The department also administers the Sir Joseph Whitworth engineering research scholarships. Other scientific departments of the Government are aids to research, as, for instance, the Ordnance and the Geological Surveys, the Royal Mint, the Natural History Museum, Kew Gardens, and other lesser establishments in Scotland and Ireland; to which may be added, to some extent, the Standards Department of the Board of Trade, as well as municipal museums, which are gradually spreading over the country. For direct assistance to voluntary efforts the Treasury contributes £4,000 a year to the Royal Society for the promotion of research, which is administered under a Board whose members represent all branches of science. The Treasury, moreover, contributes to marine biological observatories, and in recent years has defrayed the cost of various expeditions for biological and astronomical research, which in the case of the "Challenger" expedition involved very large sums of money.

In addition to these direct aids to science, Parliament, under the Local Taxation Act, handed over to the county councils a sum, which amounted in the year 1893 to £615,000, to be expended on technical education. In many country districts, so far as the advancement of real scientific technical progress in the nation is concerned, much of this money has been wasted for want of knowledge. And whilst it cannot be said that the Government or Parliament have been indifferent to the promotion of scientific education and research, it is a source of regret that the Government did not devote some small portion of this magnificent gift to affording an object-lesson to county councils in the application of science to technical instruction, which would have suggested the principles which would most usefully guide them in the expenditure of this public money. Government assistance to science has been based mainly on the principle of helping voluntary effort. The Kew Observatory was initiated as a scientific observatory by the British Association. It is now supported by the Gassiot trust fund, and managed by the Kew Observatory Committee of the Royal Society. Observations on magnetism, on meteorology, and the record of sun-spots, as well as experiments upon new instruments for assisting meteorological, thermometrical, and photographic purposes, are being carried on there. The committee has also arranged for the verification of scientific measuring instruments, the rating of chronometers, the testing of lenses and of other scientific apparatus. This institution carries on to a limited extent some small portion of the class of work done in Germany by that magnificent institution, the Reichsanstalt at Charlottenburg, but its development is fettered by want of funds. British students of science are compelled to resort to Berlin and Paris when they require to compare their more delicate instruments and apparatus with recognised standards. There could scarcely be a more advantageous addition to the assistance which Government now gives to science than for it to allot a substantial annual sum to the extension of the Kew Observatory, in order to develop it on the model of the Reichsanstalt. It might advantageously retain its connection with the Royal Society, under the committee of management representative of the various branches of science concerned, and of all parts of Great Britain.

Conclusion.

The various agencies for scientific education have produced numerous students admirably qualified to pursue research; and at the same time almost every field of industry presents openings for improvement through the development of scientific methods. For instance, agricultural operations alone offer openings for research to the biologist, the chemist, the physicist, the geologist, the engineer, which have hitherto been largely overlooked. If students do not easily find employment, it is chiefly attributable to a want of appreciation for science in the nation at large. This want of appreciation appears to arise from the fact that those who nearly half a century ago directed the movement of national education were trained in early life in the universities, in which the value of scientific methods was not at that time fully recognised. Hence our elementary, and even our secondary and great public schools, neglected for a long time to encourage the spirit of investigation which develops originality. This defect is diminishing daily.

There is, however, a more intangible cause which may have had influence on the want of appreciation of science by the nation. The Government, which largely profits by science, aids it with money, but it has done very little to develop the national appreciation for science by recognising that its leaders are worthy of honours conferred by the State. Science is not fashionable, and science students—upon whose efforts our progress as a nation so largely depends—have not received the same measure of recognition which the State awards to services rendered by its own officials, by politicians, and by the army and by the navy, whose success in future wars will largely depend on the effective applications of science.

The reports of the British Association afford a complete chronicle of the gradual growth of scientific knowledge since 1831. They show that the association has fulfilled the objects of its founders in promoting and disseminating a knowledge of science throughout the nation. The growing connection between the sciences places our annual meeting in the position of an arena where representatives of the different sciences have the opportunity of criticising new discoveries and testing the value of fresh proposals, and the presidential and sectional addresses operate as an annual stock-taking of progress in the several branches of science represented in the sections. Every year the field of usefulness of the association is widening. For, whether with the geologist we seek to write the history of the crust of the earth, or with the biologist to trace out the evolution of its inhabitants, or whether with the astronomer, the chemist, and the physicist we endeavour to unravel the constitution of the sun and the planets or the genesis of the nebulæ and stars which make up the universe, on every side we find ourselves surrounded by mysteries which await solution. We are only at the beginning of work.

I have, therefore, full confidence that the future records of the British Association will chronicle a still greater progress than that already achieved, and that the British nation will maintain its leading position amongst the nations of the world, if it will energetically continue its voluntary efforts to promote research, supplemented by that additional help from the Government which ought never to be withheld when a clear case of scientific utility has been established.

ADDRESS TO THE MATHEMATICAL AND PHYSICAL SECTION OF THE BRITISH ASSOCIATION.

BY PROF. W. M. HICKS, M A, D SC., F.R S., PRESIDENT OF THE SECTION.

In making a choice of subject for my address, the difficulty is not one of finding material but of making selection. The field covered by this section is a wide one. Investigation is active in every part of it, and is being rewarded with a continuous stream of new discoveries and with the growth of that co-ordination and correlation of facts which is the surest sign of real advancement in science. The ultimate aim of pure science is to be able to explain the most complicated phenomena of Nature as flowing by the fewest possible laws from the simplest fundamental data. A statement of a law is either a confession of ignorance or a mnemonic convenience. It is the latter if it is deducible by logical reasoning from other laws. It is the former when it is only discovered as a fact to be a law. While, on the one hand, the end of scientific investigation is the discovery of laws; on the other, science will have reached its highest goal when it shall have reduced ultimate laws to one or two, the necessity of which lies outside the sphere of our cognition. These ultimate laws—in the domain of physical science at least—will be the dynamical laws of the relations of matter to number, space, and time. The ultimate data will be number, matter, space, and time themselves. When these relations shall be known, all physical phenomena will be a branch of pure mathematics. We shall have done away with the necessity of the conception of potential energy, even if it may still be convenient to retain it; and—if it should be found that all phenomena are manifestations of motion of one single continuous medium—the idea of force will be banished also, and the study of dynamics replaced by the study of the equation of continuity.

Before, however, this can be attained, we must have the working drawings of the details of the mechanism we have to deal with. These details lie outside the scope of our bodily senses; we cannot see, or feel, or hear them, and this, not because they are unseeable, but because our senses are too coarse-grained to transmit impressions of them to our mind. The ordinary methods of investi-

Digitized by Google

gation here fails us; we must proceed by a special method, and make a bridge of communication between the mechanism and our senses by means of hypotheses. By our imagination, experience, intuition, we form theories; we deduce the consequences of these theories on phenomena which come within the range of our senses, and reject or modify and try again. It is a slow and laborious process. The wreckage of rejected theories is appalling; but a knowledge of what actually goes on behind what we can see or feel is surely, if slowly, being attained. It is the rejected theories which have been the necessary steps towards formulating others nearer the truth. It would be an extremely interesting study to consider the history of these discarded theories; to show the part they have taken in the evolution of truer conceptions, and to trace the persistence and modification of typical ideas from one stratum of theories to a later. I propose, however, to ask your attention for a short time to one of these special theories—or, rather, to two related theories—on the constitution of matter and of the ether. They are known as the vortex atom theory of matter, and the vortex sponge theory of the ether. The former has been before the scientific world for a quarter of a century—since its first suggestion by Lord Kelvin in 1867; the second for about half that time. In what I have to say I wish to take the position, not of an advocate for or against, but simply as a prospector attempting to estimate what return is likely to be obtained by laying down plant to develop an unknown district. This is, in fact, the state of these two theories at present. Extremely little progress has been made in their mathematical development, and until this has been done more completely we cannot test them as to their powers of adequately explaining physical phenomena.

The theory of the rigid atom has been a very fruitful one, especially in explaining the properties of matter in the gaseous state; but it gives no explanation of the apparent forces which hold atoms together, and in many other respects it requires supplementing. The elastic solid ether explains much, but there are difficulties connected with it—especially in connection with reflection and refraction—which decide against it. The mathematical rotational ether of MacCullagh is admirably adapted to meet these difficulties, but he could give no physical conception of its mechanism. Maxwell and Faraday proposed a special ether for electrical and magnetic actions. Maxwell's identification of the latter with the luminiferous ether, his deduction of the velocity of propagation of light and of indices of refraction in terms of known electrical and magnetic constants, will form one of the landmarks in the history of science. This ether requires the same mathematical treatment as that of MacCullagh. Lord Kelvin's gyrostatic model of an ether is also of the MacCullagh type. Lastly, we have Lord Kelvin's labile ether, which again avoids the objections to the elastic solid ether. In MacCullagh's type of ether the energy of the medium when disturbed depends only on the twists produced in it. This ether has recently been mathematically discussed by Dr. Larmor, who has shown that it is adequate to explain all the various phenomena of light, electricity, and magnetism. To this I hope to return later. Meanwhile, it may be borne in mind that the vortex sponge ether belongs to MacCullagh's type.

Already, before a formal theory of a fluid ether had been attempted, Lord Kelvin had proposed his theory of vortex atoms. The permanence of a vortex filament with its infinite flexibility, its fundamental simplicity with its potential capacity for complexity, struck the scientific imagination as the thing which was wanted. Unfortunately, the mathematical difficulties connected with the discussion of these motions, especially the reactions of one on another, have retarded the full development of the theory. Two objections in chief have been raised against it—viz., the difficulty of accounting for the densities of various kinds of matter—and the fact that in a vortex ring the velocity of translation decreases as the energy increases. There are two ways of dealing with a difficulty occurring in a general theory—one is to give up the theory, the other is to try and see if it can be modified to get over the difficulty. Such difficulties are to be welcomed as means of help in arriving at greater exactness in details. It is a mistake to submit too readily to crucial experiments. The very valid crucial objection of Stokes to MacCullagh's ether is a case in point. It drew away attention from a theory which, in the light of later developments, gives great hope of leading us to correct ideas. As Larmor has pointed out, this objection vanishes when we have intrinsic rotations in the ether itself. A special danger to guard against is the importation into one theory of ideas which have grown out of one essentially different. This remark has reference to the apparent difficulty of decrease of velocity with increased energy.

Maxwell was, I believe, the first to point out the difficulty of explaining the masses of the elements on the vortex atom hypothesis. To me it has always appeared one of the greatest stumbling-blocks to the acceptance of the theory. We have always been accustomed to regard the ether as of extreme tenuity, as of a density extremely though not infinitely smaller than that of gross matter, and we carry in our minds that Lord Kelvin has given an inferior limit of about 10^{-19}. There are two directions in which to seek a solution. The first is to cut the knot by supposing that the atoms of gross matter are composed of filaments whose rotating cores are of much greater density than the ether itself. The second is to remember that Lord Kelvin's number was obtained on the supposition of elastic solid ether, and does not necessarily apply to the vortex sponge. Unfortunately, however, for the first explanation, the mathematical discussion* shows that a ring cannot be stable unless the density of the fluid outside the core is equal to, or greater than, that inside. This instability also cannot be cured by supposing an additional circulation added outside the core. Unless, therefore, some modification of the theory can be made to secure stability, this idea of dense fluid cores must be given up.

We seem, therefore, forced back to the conclusion that the density of the ether must be comparable with that of ordinary matter. The effective mass of any atom is not composed of that of its core alone, but also of that portion of the surrounding ether which is carried along with it as it moves through the medium. Thus a rigid sphere moving in a liquid behaves as if its mass were increased by half that of the displaced liquid. In the case of a vortex filament the ratio of effective to actual mass may be much larger. In this explanation the density of the matter composing an atom is the same for all, whilst their masses depend on their volumes and configurations combined. Now, the configuration alters with the energy, and this would make the mass depend to some extent at least on the temperature. However repugnant this may be to current ideas, we are not entitled to deny its possibility, although such an effect must be small or it would have been detected. Such a variation, if it exists, is not to be looked for by means of the ordinary gravitation balance, but by the inertia or ballistic balance. The mass of the core itself remains, of course, constant, but the effective mass—that which we can measure by the mechanical effects which the moving vortex produces—is a much more complicated matter, and requires much fuller consideration than has been given to it.

The conditions of stability allow us to assume vacuous cores or cores of less density than the rest of the medium. If we do this, then the density of the ether itself may be greater than that of gross matter. Until, however, we meet with phenomena whose explanation requires this assumption, it would seem preferable to take the density everywhere the same. In this case the density of the ether must be rather less than the apparent density of the lightest of any of the elements, taking the apparent density to mean the effective mass of a vortex atom per its volume. This will probably be commensurable with the density of the matter in its most compressed state, and will lie between ·5 and 1—comparable, that is to say, with the density of water. Larmor, from a special form of hypothesis for a magnetic field in the rotationally elastic ether, is led to assign a density of the same order of magnitude. If the density be given it is easy to calculate the intrinsic energy per cubic centimetre in the medium. The velocity of propagation of light in a vortex sponge ether, as deduced by Lord Kelvin, is ·47 time the mean square velocity of the intrinsic motion of the medium. This gives for the mean square velocity $6{\cdot}3 \times 10^{10}$cm. per second. If we follow Lord Kelvin and use for comparison the energy of radiation per cubic centimetre near the sun, or, say, 1·8 erg per cubic centimetre, the resulting density will be 10^{-21}. The energy per cubic centimetre in a magnetic field of 15,000 C.G.S. units is about one joule. If we take this for comparison we get a density of 10^{-14}. But the intrinsic energy of the fluid must be extremely great compared with the energy it has to transmit. If it were a million times greater the density would still only amount to 10^{-8}—comparable with the density of the residual gas in our highest vacua. To account for the density of gross matter on the supposition that it is built up out of the same material as the ether leads to a density between ·5 and 1. This gives the enormous energy of 10^{14} joules per cubic centimetre. In other words, the energy contained in one cubic centimetre of the ether is sufficient to raise a kilometre cube of lead one metre high against its weight. Thus the difficulty in explaining the mass of ordinary matter seems to reduce itself to a difficulty in believing that the ether possesses such an enormous store of energy. It may be that there are special reasons against such a large density. Larmor refers to the large forcives which would be called into play by hydrodynamical motions. Perhaps an answer to this may be found in the remark that where all the matter is of the same density the motions are kinematically deducible from the configuration at the instant, and are independent of the density. It is only where other causes act, such, *e.g.*, as indirectly depend on the mean pressure of the fluid or where vacuous spaces occur, that the actual value of the density may modify the measurable forcives.

Ever since Prof. J. J. Thomson proved that a vortex atom theory of matter is competent to serve as a basis of a kinetic theory of gases it has been urged by various persons as a fatal objection that the translation velocity of the atoms falls off as the temperature rises. I must confess this objection has never appealed to me. Why should not the velocity fall off? The velocity of gaseous molecules has never been directly observed, nor has it been experimentally proved that it increases with rise of temperature. We have no right to import ideas based on the kinetic theory of hard discrete atoms into the totally distinct theory of mobile atoms in continuity with the medium surrounding them. Doubtless the molecules of a gas effuse through a small orifice more quickly as the temperature rises, but it is natural to suppose that a vortex ring would do the same as its energy increases. To make the objection valid, it is necessary to show that a vortex ring passing through a small tube, comparable with its own diameter, would pass through more slowly the greater its energy. It is not, however, necessarily the case that in every vortex aggregate the velocity decreases as the energy increases. The mathematical treatment of thin vortex filaments is comparatively easy, and little attention has been paid to other cases. Let us attempt to trace the life history as to translation velocity and energy

* An error in the expression on page 768 of "Researches in the Theory of Vortex Rings," *Phil. Trans.*, part ii., 1885, vitiates the conclusion there drawn. If this be corrected the result mentioned above follows. See also Basset, *Treatise on Hydro-dynamics*, § 338, and *Amer. Jour. Math.*

Digitized by Google

of a vortex ring. We start with the energy large; the ring now has a very large aperture, and has a very thin filament. As the energy decreases the aperture becomes smaller, the filament thicker, and the velocity of translation greater. We can trace quantitatively the whole of this part of its history until the thickness of the ring has increased to about four times the diameter of the aperture, or perhaps a little further. Then the mathematical treatment employed fails us or becomes very laborious to apply. Till 18 months ago this was the only portion of its history we could trace. Then Prof. J. M. Hill published his beautiful discovery of the existence of a spherical vortex. This consists of a spherical mass of fluid in vortical motion and moving bodily through the surrounding fluid, precisely as if it were a rigid sphere. This enables us to catch a momentary glimpse, as it were, of our vortex ring some little time after it has passed out of our ken. The aperture has gone on contracting, the ring thickening, and altering the shape of its cross-section in a manner whose exact details have not yet been calculated. At last we just catch sight of it again as the aperture closes up. We find the ring has changed into a spherical ball, with still further diminished energy and increased velocity. We then lose sight of it again, but it now lengthens out, and towards the end of its course approximates to the form of a rod moving parallel to its length through the fluid with energy and velocity which again can be approximately determined. In this part of its life the velocity of translation decreases with decrease of energy. I believe it will be found, when the theory is completely worked out, that the spherical atom is the stage where this reversal of property takes place.

Even in the ring state, however, the change of velocity with energy is very small; much smaller, I think, than is generally recognised. When the energy is increased to 20 times that of the spherical vortex, the velocity is only diminished to two-thirds its previous value. If at ordinary temperatures, say 27deg. C., the vortex was in the spherical shape, then at 3,000deg. C. its velocity of translation would only have been reduced to four-fifths its value at the lower temperature, whilst the aperture of the ring would have a radius about 1·4 time that of the sphere. At 2,000deg. C. the velocity would not differ by much more than one-twentieth from its original value. In fact, near the spherical state the alteration in velocity of translation is very slow. It is therefore possible, that if the atoms of matter be vortex aggregates, the state in which we can experimentally test our theory is just that in which the mathematical discussion fails us. Other modifications tend to diminish this change of velocity. I will refer here to three only. The first is that of hollow vortices. We must not, however, postulate vacuous atoms without any rotational core at all; for in this case we should probably lose the essential property of permanence. The question has not been fully investigated, but there can be little doubt but that by diminishing the energy of a completely hollow vortex we can cause it to disappear. We can certainly create one in a perfect fluid. Secondly, J. J. Thomson has shown that if a molecule be composed of linked filaments, the energy increases as the components move further apart. In such a case an extra supply of energy goes to expanding the molecule, and less, if any, to increasing the aperture. Lastly, a modification of the atomic motion, to which I shall refer later, and which seems called for to explain the magnetic rotation of the plane of polarisation of light, will also tend to lessen the change of size, and therefore change of velocity with change of energy, even if it does not reverse the property.

If we pass on to consider how a vortex atom theory lends itself to the explanation of physical and chemical properties of matter independently of what may be called ether-relations, we find that we owe almost all our knowledge on this point to the work of Prof. J. J. Thomson, which obtained the Adams prize in 1882. This, however, is confined to the treatment of thin vortex rings, still leaving a wide field for future investigation in connection with thick rings and with vortex aggregates which produce no cyclosis in the surrounding medium. His work is an extremely suggestive one. He shows that such a theory is capable not only of explaining the gaseous laws of a so-called perfect gas, but possibly also the slight deviations therefrom. Quite as striking is his explanation of chemical combination—an explanation which flows quite naturally from the theory. A vortex filament can be linked on itself; two or more can be linked together, like helices drawn on an anchor-ring; or, lastly, several can be arranged together like parallel rings successively threading one another. In the latter case, for such an arrangement to be permanent, the strengths of each ring must be the same, and, further, not more than six can thus be combined together. The linked vortices will be in permanent combination on account of their linkedness; the other arrangement may be permanent if subject to no external actions. If, however, they are disturbed by the presence of other vortices they may break up. When atoms are thus combined to form a compound, a certain number of molecules will always be dissociated. The compound will be permanent when the ratio of the average paired time to the unpaired time of any atom is large. Thomson considers every filament to be of the same strength. Then an atom consisting of two links will behave like a ring of twice the strength, one of three links, of three times the strength, and so on. On this theory chemical compounds are to be regarded as systems of rings, not linked into one another but close together, and all engaged in the operation of threading each other. The conditions for permanence are: (1) the strength of each ring must be the same, (2) the number must be less than six. Now apply this. H and Cl have equal linkings, therefore equal strength. Consequently, we can have molecules of HCl, or any combinations up to six atoms per molecule, although the simpler one is most likely. O has twice the linking, therefore the strength double. Hence one of H and one of O cannot revolve in permanent connection. We require first to arrange two of H together to form one system. This system has the same strength as O, and can therefore revolve in permanent connection, and we get the water molecule. Or we may take two of the O atoms and one of the double H molecule, and they can form a triple system of three rings threading one another in permanent connection, and we get the molecule H_2O_2. This short example will be sufficient to indicate how the theory gives a complete account of valency.

The energy of rings thus combined is less than when free; consequently they are stable, and the act of combination sets free energy. Further, Thomson points out that for two rings to combine their sizes must be about the same when they come into proximity; consequently, combination can only occur between two limits of temperature corresponding to the energies within which the radii of both kinds of rings are near an equality. We can easily extend Thomson's reasoning to explain the combination of two elements by the presence of a third neutral substance. Call the two elements which are to combine A and B, and the neutral substance C. The radii of A and B are to be supposed too unequal to allow them to come close enough together to combine. If, now, at the given temperature the C atom has a radius intermediate to those of A and B, it is more nearly equal to each than they are to one another; C picks up one of A, and after a short time drops it; A will leave C with its radius brought up, say, to closer equality with it. The same thing happens with the B atoms, and they leave C with their radii brought down to closer equality with it. The result is that A and B are brought into closer equality with one another, and if this is of sufficient amount they can combine, and do so, while C remains as before and apparently inert. Thomson's theory of chemical combination applies only to thin rings. Something analogous may hold also for thick rings, but it is clearly inapplicable to vortex aggregates similar to that of Hill's. We are not confined, however, to this particular kind of association of vortex atoms in a molecule. For instance, I have recently found that one of Hill's vortices can swallow up another and retain it inside in relative equilibrium. The matter requires fuller discussion, but it seems to open up another mode of chemical combination.

A most important matter which has not yet been discussed at all is the relation between the mean energy of the vortex cores, and the energy of the medium itself when the atoms are close enough to affect each other's motions (as in a gas). The fundamental ideas are quite different from those underlying the well-known kinetic theory of gases of hard atoms. Nevertheless, many of the results must be very similar, based as both are on dynamical ideas. Whether it will avoid certain difficulties of the latter, especially those connected with the ratio of the specific heats, remain to be seen. The first desideratum is the determination of the equilibrium of energy between vortices and medium, and before this is done it is useless to speculate further in this region.

A vortex atom theory of matter carries with it the necessity of a fluid ether. If such a fluid is to transmit transversal radiations, some kind of quasi elasticity must be produced in it. This can be done by supposing it to possess energetic rotational motions whose mean velocity is zero, within a volume whose linear dimension is small compared with the wave-length of light, but whose velocity of mean square is considerable. That an ether thus constituted is capable of transmitting transverse vibrations I showed before this section at the Aberdeen meeting of the association by considering a medium composed of closely-packed discrete small vortex rings. Lord Kelvin at the Manchester meeting discussed the question much more thoroughly and satisfactorily, and deduced that the velocity of propagation was $\sqrt{2/3}$ times the velocity of mean square of the turbulent motion. We can make little further progress until we know something of the arrangement of the small motions which confer the quasi-rigidity. This may be completely irregular and unsteady, or arranged in some definite order of steady motions. I am inclined to the view that the latter is nearer the truth. In this case we should expect a regular structure of small cells in which the motions are all similar. By the word cell I do not mean a small vessel bounded by walls, but a portion of the fluid in which the motion is a complete system in itself. Such a theory might be called a cell theory of the ether. The simplest type, perhaps, is to suppose the medium spaced into rectangular boxes, in each of which the motion may be specified as follows. Holding the box with one set of faces horizontal the fluid streams up in the centre of the box, then turns round, flows down the sides and up the centre again. In fact, it behaves like a Hill's vortex squeezed from a spherical into a box form. Each box has thus rotational circulation complete in itself. The six adjoining compartments have their motion the same in kind but in the reverse direction, and so on. In this way we get continuous and energetic small motions throughout the medium, and the state is a stable one. If there is a shear, so that each cell becomes slightly rhomboidal, the rotational motions inside tend to prevent it, and thus propagate the disturbance, but the cells produce no effect on the general irrotational motion of the fluid, at least when the irrotational velocities are small compared with those of the propagation of light. In this case the rate at which the cells adjust themselves to an equilibrium position is far quicker than the rate at which this equilibrium distribution is disturbed by the gross motions. The linear dimensions of the cells must be small compared with the wave lengths of light. They must probably be small also compared with the atoms of gross matter, which are themselves small compared with the same standard.

We may regard each cell as a dynamical system by itself, into which we pour or take away energy. This added energy will depend only on the shape into which the box is de-formed. We may then, for our convenience in considering the gross motions of

Digitized by Google

the medium as a whole—*i.e.*, our secondary medium—regard these as interlocked systems, neglect the direct consideration of the motions inside them, but regard the energy which they absorb as a potential function for the general motion. This potential function will contain terms of two kinds, one involving the shear of the cells, and this shear will be the same as the rotational deformation in the secondary medium. The second will depend on alterations in the ratios of the edges of the cells, including other changes of form involving no rotations. The former will give rise to waves of transversal displacements. The second cannot be transmitted as waves, but may produce local effects.

If a continuous solid be placed in such a medium, the cells will rearrange themselves so as to keep the continuity of their motions. The cells will become distorted (but without resultant shear), and a static stress will be set up. We have then to deal with the primary stuff itself whose rotation gives a structure to the ether, and the structural ether itself. The former we may call the primary medium. The ether which can transmit transversal disturbances, and which is built up out of the first, we may call the secondary medium. Whether an atom of matter is to be considered as a vortical mass of the primary or of the secondary medium is a matter to be left open in the present state of the theory.

At the Bath meeting of this association I sketched out a theory of the electrical action of a fluid ether in which electrical lines of force were vortex filaments combined with an equivalent number of hollow vortices of the same vortical strength. An electric charge on a body depended on the number of ends of filaments abutting on it, the sign being determined by the direction of rotation of the filament looked at from the body. This theory gave a complete account of electrostatic actions, both quantitatively and qualitatively, and a more speculative one as to currents and magnetism. I could only succeed in proving at that time that if the filaments were distributed according to the same laws as electric lines of force, the distribution would be one of equilibrium. Larmor has recently proved that this is also the necessary distribution for any type of a rotationally elastic ether, and consequently also for this particular case. Currents along a wire were supposed to consist of the ends of filaments running along it, with disappearance of the hollow companions, the filaments producing at the same time a circulation round the wire. A magnetic field was thus to be produced by a flow of the ether, but probably with the necessary accompaniment of rotational elements in it. This latter, however, was clearly wrong, because each kind of filament would produce a circulation in opposite directions. The correct deduction would have been to lay stress on the fact that the field is due to the motion through the stationary ether of the vortex filaments, the field being perpendicular to the filament and to its direction of motion. This motion would doubtless produce stresses in the cell-ether due to deformations of the cells, and be the proximate cause of the mechanical forces in the field. In any case, it is not difficult to show that a magnetic field cannot be due to an irrotational flow of the ether alone. To prove this, consider a straight conductor moving parallel to itself and perpendicular to a uniform magnetic field. There exists a permanent potential difference between its ends. If, however, the field consists of a flow of ether, the effect is the same as if the conductor is at rest, and the direction of the magnetic field shifted through an angle. But this is the case of a conductor at rest in a field, and there is therefore no potential difference between the ends. Hence a magnetic field must consist of some structure across which the conductor cuts. A field may possibly demand a flow of the ether, but, if so, it must carry in it some structure definitely oriented at each point to the direction of flow. Such electrostatic and magnetic fields produce states of motion in the medium, but no bodily flow in it; consequently we ought not to expect an effect to be produced on the velocity of transmission of light through it

The fundamental postulate underlying this explanation of electric action is that when two different kinds of matter are brought into contact a distribution of vortex filaments in the neighbourhood takes place, so that a larger number stretch from one to the other than in the opposite direction—the distinction between positive and negative ends being that already indicated. To see how such a distribution may be caused, let us consider each vortex atom to be composed of a vortical mass of our secondary medium or cell-structure ether. The atom is much larger than a cell, and contains practically an infinite number of them. It is a dynamical system of these cells with equilibrium of energy throughout its volume. The second atom is a dynamical system with a different equilibrium of energy. Where they come into contact there will be a certain surface rearrangement, which will show itself as a surface distribution of energy in a similar manner to that which exists between a molar collection of one kind of molecules in contact with one of another, and which shows itself in the phenmenon which we call surface tension. In the present case the effect may take place at the interface of two atomic systems in actual contact, or be a difference effect between the two interfaces of the ether and each atom when the latter are sufficiently close. The surface effect we are now considering shows itself as contact electricity. Such a distribution of small vortex filaments, stretching from one atom to another, will tend to hold them together. We therefore get an additional cause for aggregation of atoms. This does not exclude the others already referred to. They may all act concurrently, some producing one effect, some another—one combining. perhaps, unknown primitive atoms into elements, one elements into chemical compounds, and another producing the cohesion of matter into masses.

On this theory, the difference between a conductor and a dielectric is that in a dielectric the ends of the filaments cannot pass from atom to atom, possibly because the latter never come into actual contact. In a conductor, however, we are to suppose that the atomic elements can do so. When a current is flowing, a filament and its equivalent hollow stretch between two neighbouring atoms, they are pulled into contact (or their motions bring them into contact), the hollow disappears, and the rotational filament joins its two ends and sails away as a small neutral vortex ring into the surrounding medium, or returns to its function as an ether cell. The atoms, being free, are now pulled back to perform a similar operation for other filaments. The result is that the atoms are set into violent vibrations, causing the heating of the conductor. When, however, the metal is at absolute zero of temperature there is no motion, the atoms are already in contact, and there is no resistance, as the observation of Dewar and Fleming tends to show. Further, as the resistance depends on the communication of motion from molecule to molecule, we should expect the electrical conductivity of a substance to march with its thermal conductivity. Again, on this theory the resistance clearly increases with increase of distance between atoms—*i.e.*, with increase of temperature. On the contrary, in electrolytic conduction the same junction of filament ends is brought about, not by oscillations of molecule to molecule, but by disruption of the molecule and passage of atom to atom. In this case conduction is easier the more easily a molecule is split up, and thus resistance decreases with increase of temperature. To explain the laws of electrolysis it is only necessary to assume that the strength of all filaments are the same. A similar hypothesis, as we have seen, lies at the basis of J. J. Thomson's explanation of chemical combination, although it is not necessarily the case that we are dealing with the same kind of filaments. It is evident that the theory easily lends itself to his views as to the mechanism of the electric discharge through gases. The *modus operandi* of the production of the mechanical forcive on a conductor carrying a current in a magnetic field and of electro-dynamic induction is not clear. Probably the full explanation is to be found in the stresses produced in the ether owing to the deformation of the cells by the passage of the filaments through them. The fluid moves according to the equation of continuity without slip, and subject to the surface conditions at the conductors. This motion, however, distorts the cells, and stresses are called into play. Any theory which can explain the mechanical forcives and also Ohm's law, must, on the principles of the conservation of energy, also explain the induction of currents.

The magnetic rotation of the plane of polarisation of light does not depend on the structure of the ether, or on the magnetic field itself, but is a result of the atomic configuration of the matter in the field modified by the magnetism. It is generally recognised as caused by something in the field rotating round the direction of the magnetic lines of force. Now, the vortex atom, as usually pictured, is incapable of exhibiting this property. It is, however, an interesting fact, and one which I hope to demonstrate to this section during the meeting, that a vortex ring can have two simultaneous and independent cyclic motions—one the ordinary one, and another which is capable of producing just the action on light which shows itself as a rotation of the plane of polarisation. The motion is rather a complicated one to describe without a diagram, but an idea of its nature may be obtained by considering the case of a straight cylindrical vortex. The ordinary straight vortex consists, as everyone knows, of a cylinder of fluid revolving like a solid and surrounded by a fluid in irrotational motion. In the core the velocity increases from zero at the axis to a maximum at its surface. Thence it continuously decreases in the outer fluid as the distance increases. Everywhere the motion is in a plane perpendicular to the axis. Let us now consider a quite different kind of vortical motion. Suppose the fluid is flowing along the core like a viscous fluid through a pipe; the velocity is zero at the surface and a maximum at the axis Everywhere it is parallel to the axis, the vortex lines are circles in planes perpendicular to the axis, and concentric with it. Since the velocity at the surface of the core is zero, the surrounding fluid is also at rest. Now superpose this motion on the previous one, and it will be found to be steady. If a short length of this vortex be supposed cut off, bent into the shape of a circle and the ends joined, we shall have a very rough idea of the compound vortex ring of which I speak. I say a very rough idea, because the actual state of motion in a ring vortex or a Hill's vortex is not quite so simple as the analogy might lead one to think.

Now, a compound vortex atom of this kind is just what we want to produce rotation of the plane of polarisation of light. The light passing through such a vortex has the direction of vibration twisted in the wave front. In ordinary matter no such rotation is produced, because the various atoms are indifferently directed, and they neutralise each other's effects. Let, however, a magnetic field be produced, and they will range themselves so that, on the average, the primary* circulations through the apertures will point in the direction of the field. Consequently the average direction of the secondary spin will be in planes perpendicular to this, and will rotate the plane of polarisation of any light whose wave front passes them. The rotation is produced only on the light which is transmitted through the vortex. The rotation observed is a resultant effect. In fact, it is clear that in the case of refraction the optical media belong to the type in which every portion transmits the light, and not to the type in which refraction is produced by opaque bodies embedded in the ether. The atoms are only opaque if they contain vacuous cores. The question of the grip of the particles on the ether does not enter, but difference

* "Primary" refers to the motion as usually understood; "secondary," to the superposed, as explained above.

Digitized by Google

of quality—showing itself in refraction and dispersion—is due to difference in average rotational quasi-elasticity produced by the atomic circulations, and possibly absorption is due to precessional and nutational motion set up by the secondary spins. These, however, are perhaps rather vague speculations.

Instead of attempting to invent ethers, to deduce their properties from their specifications, and then seeing whether they fit in with experience, we may begin half way. We may assume different forms for the function, giving the energy of the medium when disturbed, apply general dynamical methods, and distinguish between those which are capable of explaining the phenomena we are investigating and those which are not. Invention is then called upon to devise a medium for which the desired energy function is appropriate. This was the method applied by MacCullagh to the luminiferous ether. He obtained an algebraical form of the energy-function which completely satisfied the conditions for a luminiferous ether; its essential property being that the energy depended only on the rotational displacements of its small parts. He was unable, however, to picture a stable material medium which would possess this property. We recognise now that such a medium is possible if the rotational rigidity is produced by intrinsic motions in the small parts of the medium of a gyrostatic nature. In a most masterly manner Larmor has recently investigated by general dynamical methods the possibility of explaining electric and magnetic phenomena by means of the same energy function. Electric lines of force are rotational filaments in the ether,* similar in fact to those I suggested at Bath, whilst a magnetic field consists of a flow of the ether. The same difficulty in accounting for electro-dynamic induction arises, but the general form of the equations for the electro-dynamic and magnetic fields are the same as those generally received. Towards the end of this paper he is led to postulate a theory of electrons whose convection through the ether constitutes an electric current. Two rotating round each other are supposed to produce the same effect as a vortex ring. The mass of ordinary matter is attributed to the electric inertia of these electrons. The electron itself is a centre or nucleus of rotational strain. If I express a doubt as to the possibility of the existence of these nuclei as specified, I do so with great diffidence.† Whether they can or cannot exist, however, the general results of the investigation are not affected. Since this paper was published Larmor has read a second one on the same subject before the Royal Society, developing further his theory of the electron. The publication of this will be awaited with interest. It is impossible in an address such as this to go *seriatim* into the numerous points which he takes up and illuminates, because the mathematical treatment of the general question does not lend itself easily to oral exposition even to an audience composed of professed mathematicians. There is no doubt but that this paper has put the theory of a rotationally elastic ether—and with it that of a fluid vortex ether—on a sounder basis, and will lead to its discussion and elucidation by a wider circle of investigators.

One further class of physical phenomena yet remains—viz., those of gravitation. The ether must be capable of transmitting gravitational forces as well as electric and optical effects. Does the rotational ether give any promise of doing this? No satisfactory explanation of gravitation on any theory has yet been offered. Perhaps the least unsatisfactory is that depending on the vortex atom theory of matter, which attributes it to pulsations of hollow vortex atoms. But this necessitates that they should all pulsate with the same period and in the same phase. It is very difficult to conceive how this can happen, unless, as Larmor suggests, all matter is built up of constant elements like his electrons, whose periods are necessarily all alike. It is possible that the vortex cell theory of the ether, of which I have already spoken, may suffice to explain gravitation also. The cells, besides their rotational rigidity, have, in addition, as we saw, a peculiar elasticity of form. To get an idea of how this theory may account for weight, let us suppose the simplest case where all the cells are exactly alike, and the medium is in equilibrium. Now suppose one of the cells begins to grow. It forces the medium away on all sides; the cells will be distorted in some definite way, and a strain set up. Further, this strain will be transmitted from the centre, so that the total amount across any concentric sphere will be the same. Stresses will therefore be set up in the whole medium. If a second cell begins to grow at another place it will produce also a state of strain, the total strain depending on the presence of both. The stresses called into play in the medium will produce a stress between the bodies, but it is questionable whether it would be inversely as the square of the distance. Whether it would be an attraction or repulsion can only be determined by mathematical investigation. The problem is quite determinate, though probably a very difficult one, and would be of mathematical interest quite apart from its physical importance. Since apparently the phenomena of gravitation have no direct interaction with those of light and electricity, whilst the mind rejects the possibility of two different media occupying the same space, we seem driven to look for it in an independent structure of the same medium. Such a structure is already to our hands, with its effects waiting to be determined. It may well be that it may prove to be the cause we are seeking.

The rapid survey I have attempted to make is no doubt a medley of suppositions and inferences combined with some sound deductions. This is the necessary consequence of a prospecting survey in a region whose surface has been merely scratched by pioneers. My object has been to show that this theory of an ether based on a primitive perfect fluid is one which shows very promising signs of being able to explain the various physical phenomena of our material universe. Probably—nay, certainly—the explanations suggested are not all the true ones. Some will have to be given up, others modified with further knowledge. We cannot proceed to particularise in our secondary hypotheses until we know more about the properties of such media as we have been considering. Every special problem solved in vortex motion puts us in a position to form clearer ideas of what can and what cannot happen. The whole question of vortex aggregates and their interactions is practically untouched, and a rich field is open for mathematical investigation in this portion only of the subject. In all cases, whether a fluid ether is an actual fact or not, the results obtained will be of special interest as types of fluid motion. It is at present a subject in which the mathematicians must lead the attack. I shall have attained my object in choosing this subject for my address if by it I can induce some of our younger mathematicians to take it up and work out its details.

ON SOME NEW METHODS FOR THE DELINEATION OF ALTERNATE-CURRENT WAVE-FORMS.*

BY JAMES MARK BARR, W. BECKIT BURNIE, AND C. RODGERS, B.SC.

With the progress of alternate-current research it becomes more and more necessary to have a reliable, rapid, and accurate means of determining the wave-forms of currents and potential differences. The method now generally in use—namely, the determining of a number of points on the curve and subsequent drawing of a line through these points—though accurate, is tedious, and requires a skilled experimenter. What we need is an apparatus which will automatically record the shape of the wave.

Some years ago Dr. Frölich attempted to use an optical arrangement for showing the shape of the wave. This apparatus consisted of a telephone receiver, the coil of which carried the alternating current, and to the diaphragm of which a mirror was fixed. The diaphragm vibrated with the variations of the current, and a beam of light reflected from the mirror at any moment indicated by its deflection the intensity of the current in the coil of the receiver. This beam of light fell upon a revolving mirror, which imparted to it an independent motion at right angles to that due to the vibrations of the telephone diaphragm. By this means there was traced upon a screen a luminous wave-form. Had this arrangement worked satisfactorily, the wave-form could have been photographed and a permanent record instantaneously obtained, but it was rendered totally useless for ordinary frequencies by errors due to the inertia of the moving parts.

This morning we propose to describe an apparatus which we believe overcomes these difficulties, and automatically records with great rapidity the wave-form. We employ a combination of two motions at right angles of a spot of light relatively to a screen; an ordinary contact disc is used, but the contact brush is slowly and continuously moved through its successive angular positions. Contact is thus made each time at a slightly different position of the armature. Thus, the potential difference at each contact differs slightly from that at the preceding contact. This potential difference is used to charge a condenser across the terminals of which is connected either a reflecting electrometer or a high-resistance galvanometer. The deflection of the instrument so used follows the value of the potential difference of the wave-form to be determined, and accurately follows it, for the mean rate of variation of the potential difference between the terminals of the condenser is exceedingly small in comparison with the rate of change of the E.M.F. to be investigated. This deflection gives us one of the component motions. The other motion of the light spot is made to be proportional to the angular movement of the contact brush.

Fig. 1 shows the arrangement of the contact disc and accessories, a galvanometer being used, for which an electrometer might be substituted. In this diagram, for the sake of clearness, the vulcanite foundation work is omitted and the brass only shown. Our motor having four poles, we have used two knife-edge contacts placed diametrically opposite, which give us one contact per wave. D_1 is the contact disc, which is rigidly fixed to the shaft of the dynamo or motor, and to it are attached the knife-edges just mentioned. The rings, D_2 and D_3, and the rods and brushes, B_1 and B_4, are mounted on one piece of vulcanite loose upon the shaft, and are revolved slowly. The brush B_1 is joined to the ring D_2, with which the brush B_2 is in permanent connection, so that when the brush B_1 makes contact with the knife-edges the condenser, C, is charged to the potential difference between the terminals, T_1 T_2. The con-

* The necessity that the filaments shall be in pairs does not seem to be recognised. This is, however, essential. Moreover, if the complementary circulations of the filaments between, say, a plate condenser be placed otherwhere than in the same region, the filaments, between the plates must rotate as a whole—that is, an electric field would always be combined with the magnetic one.

† It would appear that the same results would flow if two particles oppositely electrified—*i.e.*, joined by two complementary filaments, as already described—were to rotate round each other.

* Paper read at the meeting of the British Association at Ipswich.

Digitized by Google

denser is throughout the whole revolution of the disc D_1 discharging through the galvanometer, G, by way of B_3, B_4, B_5, and the resistance, R. As the brushes, B_1 and B_4, are moved slowly round, a succession of charges passes through the galvanometer, the value of each of which is proportional to the instantaneous E.M.F., and the required movement of the galvanometer is obtained. The relative movement of the spot of light at right angles to that due to the galvanometer may be produced in a variety of ways—by a moving screen, by a revolving mirror, or, as in the apparatus which we have constructed, by an oscillating mirror. This mirror is shown in Fig. 2, which is a plan of the general arrangement, and is marked M. Mechanically connected with the disc, D_2 D_3 (Fig. 1), and moving with the same angular velocity, is a cam, marked K, which is shown in Fig. 2. The mirror, M, is pivoted about a horizontal axis, and is oscillated by the arm, *a*, which bears on the cam. The arm is kept pressed against the working edge of the cam by the spring, S. If the edge of the cam is properly shaped, the horizontal motion of the spot of light in synchronism with the angular motion of the brush is obtained.

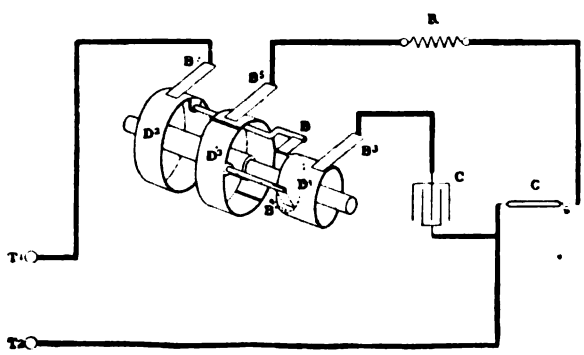

FIG. 1.

We have now two motions at right angles, and by combining them during the oscillation of the mirror, M, in one direction we cause the spot to trace out a wave-form on the screen, P. The spot of light, however, during the return oscillation would trace the wave reversed, and interfere with the true wave image. In order to prevent this, the ring D_3 (Fig. 1) is discontinuous, so that the brush B_5, during the return oscillation, breaks contact with the galvanometer circuit, and the spot draws the zero line. By placing a piece of sensitised paper or a sensitive plate on the screen a permanent record of the course of the spot is obtained. The angular velocity of the moving brushes may be made so small that a well-damped instrument even of long period may be used. For use with an ordinary electrometer, the plane mirror may be made to oscillate about a horizontal axis and a curve drawn, the zero line of which is vertical. The cam may be dispensed with, and the screen itself moved either horizontally or vertically with gearing, or a cylinder covered with sensitive paper may be attached to the

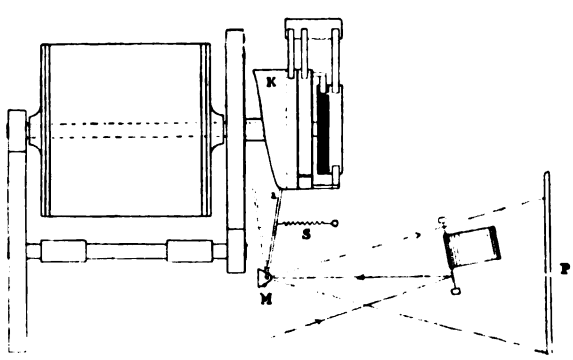

FIG. 2.

moving brushes, and the deflection of this made to move the spot axially on the cylinder. But there are certain disadvantages attached to this method of experimenting which made us decide to construct the apparatus with the cam. There have been brought out lately several methods for building up current and E.M.F. wave-shapes. In using this apparatus during the process of building up wave-forms, the required shape may be drawn upon the screen and the course of the spot of light observed, it being noted wherein it differs from that curve, and steps being taken to ensure a close coincidence. With the form of apparatus in which the cam is not used, this process is more difficult.

A short time ago Dr. Fleming published a new and ingenious method of plotting wave-forms with polar co-ordinates, and of directly obtaining therefrom the root mean square value. Our apparatus may be easily modified so as to obtain a record of one of these polar waves. For this purpose, the slow-moving disc must be mounted on the extreme end of the shaft, and a sensitised screen must be fitted thereon. The instrument must be so placed that the zero position of the spot of light is on the centre of the disc and the deflection along one of the radii. The curve traced will then be of the required form. By a system of mirrors it would be possible to obtain the same result with the screen fixed, but this appears to offer no special advantages.

The galvanometer which we have up to the present used with our apparatus is of the Ayrton-Mather type with a horizontal coil, but no silver tube for damping. The coil is wound with 260 turns of wire, 1·4 mils in diameter, with a resistance of 400 ohms. The period is small, being about ten-fiftieths of a second. The damping is effected by a light glass arm dipping into an oil vessel, the height of which can be adjusted. An electrometer would have been preferable, but it is difficult to obtain an electrometer of sufficiently small period. For tracing the wave very slowly an electrometer may be used, but one of the advantages of our method over the methods in ordinary use is the rapidity with which the wave may be traced. In many experiments there is a variation of speed with time, against the effects of which it is necessary to guard, but in tracing a wave in a few seconds no appreciable variation of speed can take place. We have here a photograph of a potential difference wave-form taken by means of this apparatus. As the experiments were performed after the closing of the college, the only current available was that from a small four-pole motor transformer. The consequence is that there is a series of steps in the wave due to the commutator segments which were comparatively few in number. This, of course, gives a wave-form not so nice in appearance as an ordinary sine wave, but it is so much the more a severe test of our apparatus.

In determining the curve by the ordinary method the irregularities would not have been so clearly seen unless an exceedingly large number of points had been taken. The spot of light was rather unsatisfactory, there being a small auxiliary spot by the side of the main spot. This small spot traced a

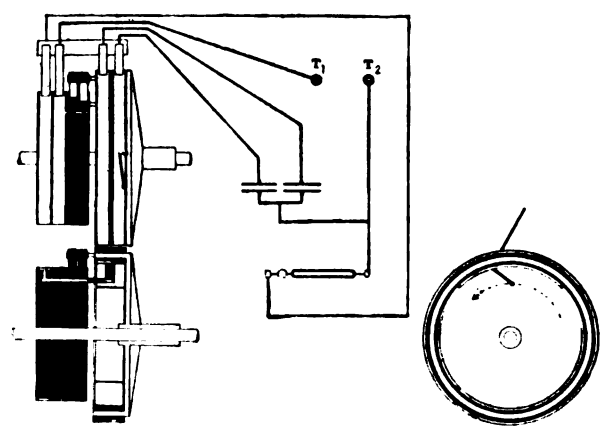

FIG. 3.

curve itself which can be distinctly seen on the photograph, and which detracts somewhat from the clearness. We should much have liked to show a smooth wave-form taken with this apparatus and a satisfactory spot of light, but the constructive work was finished only last Saturday, and we have not had time to perform many experiments with it. If the spot of light were made to trace out the wave-form sufficiently rapidly, the curve would appear as a continuous luminous line. This can be effected with the apparatus as it now stands with high frequencies. With low frequencies, however, that is impossible. For instance, with a frequency of 80 alternations per second we obtain 80 contacts per wave. But since, for the line to appear continuous, the slow-moving disc must make at least five revolutions per second, the number of contacts cannot exceed eight per complete period, or four per half wave—an obviously insufficient number.

We have here (Fig. 3) a diagram illustrating a method by which this difficulty is overcome. As before, the apparatus consists of two discs—one moving at the speed of the motor and the other a slow-moving one. The slow-moving disc carries two collecting rings, two brushes, and an internal four-part commutator. Each collecting ring is connected to a pair of opposite commutator segments, and the slow disc carries two brushes which bear on the fast disc and are connected one to each collecting ring. The fast disc also carries two collecting rings, one connected to the knife-edge and the other to the fast-revolving brush which bears on the four-part commutator of the slow-moving disc. The two brushes carried by the slow-moving disc are slightly in advance the one of the other, and the slow-moving disc is rotated so as to have a definite speed relation to the fast disc. The two condensers are charged in rapid succession as the knife-edges pass the brushes, and during the remainder of the half revolution are discharged in succession

Digitized by Google

through the four-part commutator, the fast-revolving brush, and the galvanometer. The effect is to get twice as many discharges through the galvanometer per wave as is obtained with the apparatus shown in Fig. 1. Three or more condensers can be used, the total number of contacts per wave obtained being proportional to the number of condensers used. For all ordinary purposes, however, the apparatus with one condenser will be found most convenient.

In conclusion, we must acknowledge our indebtedness to Prof. Ayrton and Mr. Mather for their kind advice, and to Mr. W. Duddell, one of our fellow-students, for his help during the construction of the apparatus.

INDIAN THUNDERSTORMS.*

BY PROF. MICHIN SMITH.

The author's experience has been most gained in the Madras district. At certain seasons of the year a marked constant recurrence of sheet lightning at dusk was noticed. The display was always near the horizon in the west or south-westerly direction. The author considered the reason of the low position of the lightning is because it takes place in the upper part of the clouds. An overhead storm, then, does not show any display of lightning. Analysing the matter further, he found that the wind was usually off the land all day, and that the time at which storms occurred varied with the time at which the S.W. wind springs up off the sea. If this is late, the storm is late, or does not occur at all. The conclusion from this is that the storms occur where the land and sea winds meet. The land winds are usually dry and more or less dusty, while the sea-breezes are moist. The author exhibited some good photographs of the two parallel clouds formed where the winds met. The frequency of the lightning flashes between the clouds was very high, often exceeding 150 flashes per minute. The author considered that the winds from the land were usually highly electrified negatively, and that the sea-breezes were positively electrified. These storms do no damage, as the whole of the discharges are aerial or between clouds.

COMPANIES' MEETINGS AND REPORTS.

BRUSH ELECTRICAL ENGINEERING COMPANY, LIMITED.

The sixth annual general meeting of this Company was held on the 23rd inst., at Cannon-street Hotel, E.C.

The **Chairman** (Mr. J. B. Braithwaite, jun.), who presided, in moving the adoption of the report and accounts (a copy of which appeared in our last issue), referring first to the balance-sheet, called attention to the fact that the amount of the Company's capital remained unchanged, while the creditors had been reduced during the year from £72,000 to £44,888 ; but the loans and overdrafts from bankers had increased from £25,000 to £78,000. The provision for depreciation on property, patents, and goodwill remained the same as last year. The contingent liability in respect of uncalled capital had been reduced from £39,697 to £5,547, which was not likely to be called up, and had, therefore, practically disappeared. On the other side of the account the item of property, patents, and goodwill had been increased by £2,487 by additions to plant during the year, and now stood at £288,874, after deducting the usual sum for amortisation of lease. Having referred to other items in the balance-sheet he remarked that the chief item which would attract their attention was the increase of the loan from the bankers from £25,000 to £78,000. Of this difference £27,000 was owing to their having reduced the amount due to their creditors from £72,000 to £44,888, and the remainder was owing to the increase of their shares and debentures in other companies, practically representing the difference between the £39,697 liability on shares they had last year and the £5,547 which they now had. Their gross profit for the past year had been £37,858, being nearly £20,000 less than that of the previous year. This decrease was owing entirely to the difficulties which had occurred in connection with their contract with the City of London Electric Lighting Company. On the other hand, their general charges had been £17,020, compared with £19,974 in the previous year. With reference to buildings and plant, their chief engineer, Mr. Raworth, had certified that these had been maintained in an efficient condition. The item of bank interest and commission, £2,227, would disappear on the issue of the additional amount of debenture stock they were now proposing to make. Last year he had stated that the loan of £25,000 from the bankers was likely to be a temporary matter, and, therefore, it was not worth while to issue additional capital to liquidate it. What he said with regard to that applied with equal force to the amount which they now owed their bankers of £78,000, and for that reason they did not propose to make any permanent addition to the capital account of the Company. They would see from the figures he would give them that it would be unwise to saddle themselves with a permanent charge for the additional £105,000 of debenture stock which they proposed to issue. On the other side of the balance-sheet they had assets more or less liquid, and which might easily come in in the form of cash for shares to the amount of £61,000, while the balance of debtors over creditors was £96,000, and the stock was worth £100,000, making a total of £257,000. Of course, he did not hope to see anything like the whole of that sum come into cash, because if they realised the whole of their stock and the whole of the difference between debtors and creditors it would mean that their business had practically come to an end. At the same time the balance of debtors over creditors was very much larger than it would be in a normal year's trading, owing to the fact of the heavy retention funds which they were obliged to allow to remain on some of their municipal lighting contracts. However, it was reasonable to suppose that the balance might be reduced to £50,000, in which case they would have £50,000 in cash, which, in addition to the shares and debentures which they were constantly realising, would give them sufficient to redeem the whole amount of the debenture stock they were now proposing to issue. They proposed, therefore, to make the new stock redeemable at 105 per cent. at six months' notice at any time, and he thought it probable that unless some very unexpected extension of their business took place in the course of the next two or three years the whole or a considerable portion of that debenture stock would be redeemed. With reference to dividend, under the articles of association, the preference shares were a first charge over the ordinary shares to the extent of a full 6 per cent. dividend from the net profits of the year, but they were not cumulative as from one year to another. During this year they had earned £7,400 net, of which the preference shareholders had received £5 400. There was, therefore, another £2,000 odd to come to them which he hoped they would receive next year, in addition to their ordinary dividend of 6 per cent. Having dealt with the accounts and balance-sheet of the Company, the Chairman continued : Of course the first question you will want to hear about is the circumstances in connection with the contract with the City of London Electric Lighting Company, which has unfortunately turned what would have been the best year in the Company's existence into the worst. That only illustrates the disadvantages, in some ways, of having contracts of such very great magnitude. But it may be a matter of satisfaction to the shareholders to know that, apart from the City of London Electric Lighting Company's contract, the past year has been the best in the history of the Company. We have made more profits than we have ever done before, apart from that one contract, and I think it is due to the shareholders to know that, because otherwise they might consider that this large drop in the profits was due to a falling off in our business generally, or, any rate, to our not being able to conduct the business at a profit. This unfortunate result is entirely due to the extraordinary and unforeseen circumstances which have arisen in connection with the contract I have referred to. I do not think I am at liberty to go into exact details, but I think I can give you in very general terms sufficient reasons to enable you to understand the position in which we have been placed. The contract with the City of London Electric Lighting Company was one of considerable magnitude, amounting in all to somewhere about £300,000, and under that contract the decision of all points connected with it was left absolutely to the engineer of the City of London Electric Lighting Company for the time being. That, of course, is a very usual provision, and no doubt would have been perfectly satisfactory under ordinary circumstances, but we have been unfortunate enough to have no less than three engineers in the course of the existence of that contract, each of whom, as he was appointed, became practically a supreme judge as to whether the contract was being carried out satisfactorily or not. Now, I need hardly tell you gentlemen, that among electrical engineers, each has his own particular views, and therefore you will readily understand that the change of engineers which took place in the City of London Electric Lighting Company in December last year was a very unfortunate thing for us when it turned out that the new engineer had very different ideas of what the obligations under the contract were to those which his predecessor had had. We have done the very best we could under the difficult circumstances in which we have been placed. In view of the fact that the engineer is made supreme judge, there was practically no alternative before us but to accept the altered view of what were the obligations under the contract, or resort to an exceedingly expensive lawsuit ; and I hope you will give us credit for having, under the circumstances, made the best arrangement we could, although the result has been to have an exceedingly serious effect upon our profits for the past year. We have therefore endeavoured to adjust matters with the new engineer of the City of London Electric Lighting Company on the basis that he wishes, and that having been accomplished, work under the contract is again proceeding. With regard to the general prospects of our Company, we are in the fortunate position of having our works fully occupied with orders for some months in advance During the year we have carried out and opened central stations for electric lighting for the Municipalities of Worcester and of Leicester, and we have also opened for the County of London and Brush Provincial Company a station for the supply of electricity to Dover. All those works have turned out entirely satisfactorily, and we have work of a similar character in hand in our shops for St. Luke's, Clerkenwell, and Wandsworth,

* Abstract of paper read at the meeting of the British Association at Ipswich.

Digitized by Google

for the County of London and Brush Provincial Company, and for various other stations up and down the country, so that as regards the electrical shops we are full of orders and have plenty of work in hand. With reference to our car-shops, we are also full of orders there at the present time. We have been building locomotives and rolling-stock for the Beira Railway, about which undertaking some of you may have heard a good deal; it is one of the new railways that has been constructed for the opening up of South Africa. We have also in hand at the present time a large number of cars for the Rouen Tramways Company, which are being equipped with electricity. With regard to the engine building side of our works, there again we have carried out a considerable number of orders. We have already sold about 35,000 h.p. of engines, and our chief engineer, Mr. Raworth, has just introduced a new enclosed high-speed engine, from which we hope great things in the future. It is an engine which will be equally suited for electrical work and all other kinds of work to which steam-engines are generally put; we certainly hope it will bring considerable additional orders into our engine-shop, and that it will give us an engine which we can manufacture at a very considerable profit. After all, the chief duty we have towards our shareholders is to find articles which, in the present severe state of competition, we can manufacture at a reasonable profit, and we believe this new engine will be one of those articles. With regard to electric traction—for electric traction is a thing that we must look to very largely in the future, to keep our electrical engineering shops full—up to the present time we may say that in Great Britain it has been practically a dead letter. If you go into the United States of America or Canada you will find that even small villages have their electric tramways and electric railways of different kinds. I suppose in the States now there are literally thousands of miles of tramways worked by electricity, whereas in this country the electric tramways which are at present open can be counted on the fingers of one hand. At the same time, the thin end of the wedge has been introduced into this country, and I have no doubt that when the three or four important tramway works that are now in course of construction are opened, and the public realise the immense convenience and the immense acceleration of travel which are due to the adaptation of electricity for the working of their tramways, we shall see a very great rush of electric tramway business in this country. With reference to the working of railways by electricity, we have in England two specimens of a railway worked entirely by electricity. These are the City and South London Railway, running from the Monument to Stockwell, and the Liverpool Overhead Railway, both of which are working perfectly satisfactorily, and, as you know, there are two other important electric railways in course of construction, one belonging to the City and South London, and the other the Central London Railway, which will run from Liverpool-street to Shepherd's Bush, by way of Holborn and Oxford-street. These will be worked entirely by electricity, so you see that electric traction, even in this country, is beginning to take hold, and when we read in the American papers that the first locomotive turned out for the Baltimore and Ohio Railroad Company has drawn a freight tram weighing 1,200 tons at the rate of 15 miles an hour, and on a speed test the other day is reported to have attained a rate of 61 miles an hour without any difficulty. I think we may say the electrical industry has an enormous future before it in the direction of electric traction. Electric lighting is a firmly established industry, and is not likely to retrograde, but electric traction offers a comparatively new field, and in that direction I look to a large amount of work for our well-equipped car-sheds at Loughborough. I do not know that there is any other matter to which I need call your attention at present. One subject I might be allowed to mention, and that is that having regard to the position in which the Company has been placed by these unprecedented circumstances in connection with the City of London contract, myself and my colleagues feel it would be the right thing for us to forego half our fees in the ensuing year. That, I think, will indicate our desire to do our best for the Company in every way.

Mr. B. H. Van Tromp seconded the adoption of the report.

Mr. Ward asked whether the directors would endorse the statement that the shares and debentures in other companies to the amount of £60,000 were of full value, as the auditors in their report stated that they had not verified the market value of them. The report presented to the shareholders was the most unsatisfactory one they had ever had. In a trading company one naturally expected every now and then to have a loss, but in this case it was not a loss in trading in the ordinary sense. He could not help thinking that the directors had made a considerable blunder in allowing all matters to be referred to the engineer of the company for which they were doing work. He imagined that there should have been an umpire in case of disputes, instead of leaving it virtually in the power of the people for whom they did work to pay what they liked. Shareholders were naturally anxious to know whether the other contracts which the Company had in hand contained similar stipulations, and he hoped that the directors would be very careful in future as to the manner in which contracts were entered into.

Mr. Lamont asked if the Board could throw any light upon the fact that for a week or two before the issue of the report the shares had been going down.

Mr. Maclean enquired why an interim dividend had been paid on the ordinary shares, when, as it turned out, the preference shareholders were entitled to the whole of the profits.

The **Chairman**, in reply, said that the question of the shares and debentures in other companies was a matter to which both the directors and the auditors had given great attention. Rather more than half the total amount of £61,000—some £35,000—consisted of shares which were quoted upon the London Stock Exchange, and with regard to those he might say he should be considerably disappointed if, when they realised them, they did not make a substantial profit of some £4,000 or £5,000 on their sale. With regard to the remaining £25,000, those shares and debentures were mostly connected with undertakings in which the Company had been interested in the past. He thought he might say that in every case those undertakings were in an improving position, and in many instances the Company were in receipt of dividends from them. In the case of a similar undertaking which stood in their books for some years, they had realised its shares during the past year, and had made a handsome profit upon them. But some of those shares were valuable to the Company apart from their actual market value, inasmuch as they gave them a controlling interest in companies which supplied this Company with orders. He thought he might say that, after very anxious consideration on the point, the Board believed that the shares were well worth the figure at which they stood in the balance-sheet. With regard to the conditions of the City contract, he was not responsible for the negotiation of that contract, which was made before he became chairman of the Company, but he thought it was very probable he should have done the same had he been in the place of their then manager. It was impossible to foresee that they would have a change of engineers three times within as many years, and the circumstances were so extraordinary and unprecedented that he did not think any reasonable amount of foresight could have prevented the present difficulty. He quite agreed that it was a most unsatisfactory form of contract, for he always felt that there was a very real risk in having as sole arbitrator some gentleman who might not be very illustrious in either the electrical or engineering world; but it was the same form as that usually adopted, and was identical with the Company's municipal contracts. He would also point out that if they did not take contracts on those terms, other competitors would be only too glad to get them. With reference to there having been some apparent leaking out on the market of the probable purport of the directors' report, he could only say that this had been a matter of extreme annoyance to the managers and the directors, and to himself particularly. They were engaged in investigating the matter, but as yet without tracing anything. It was extremely annoying, because it seemed to imply that those "in the know" had been taking advantage of their knowledge to realise shares at better prices than would be possible after the report was issued. Naturally, the directors had done nothing such as had been suggested; he personally had increased his holding, because he considered their shares to be much below their intrinsic value. Regarding the interim dividend, of course when that was paid everything was proceeding entirely satisfactorily; the whole of the loss that had arisen had occurred in the second half of the financial year. He imagined the shareholders would desire that no interim dividend should be paid on the ordinary shares in the future; at any rate, that was the course the Board would probably adopt unless the shareholders instructed them to the contrary.

In answer to a question as to whether the Company had any representatives on the Board of the City of London Company, the **Chairman** replied in the negative. Originally, he said, they had two representatives—the late Duke of Marlborough (then chairman of the Brush Company) and himself. When the Duke of Marlborough died, he was not replaced, and he (the speaker), who was then their only representative, felt it his duty to withdraw from the Board of that company, not especially in connection with their contract—although he felt they had been badly treated by the City Company—but because he dissented entirely from the policy the present engineer was carrying out, in the interests of the City of London Company itself.

The resolution was carried, and Messrs. E. Woods and A. Ayres, the retiring directors, were re-elected, as were also the auditors, Messrs. Cooper Bros. and Co.; and the chairman having accepted a suggestion that a circular should be issued to the shareholders about January showing the progress of the Company, the meeting closed with the usual votes of thanks.

HALIFAX AND BERMUDAS CABLE COMPANY, LIMITED.

The report for the year ending June 30 states that the cable receipts were £4,202, as compared with £3,463 in 1893-4, the increase being due to the improvement in the general business condition of the Bermudas. The result of the working was a profit of £1,023, as compared with £329, which will reduce the debit to capital to £3,870. The cable worked with complete efficiency and its electrical condition continues excellent. The directors are glad to be able to announce that they at last obtained the assent of all the holders of the debentures to such a modification of the trust deed as permits of the application of the sinking fund to purchases or drawings. Accordingly offers for the sale of debentures to the trustees were invited in June, when £11,200 of debentures were acquired and cancelled at a cost of £10,216. It is intended to apply the sinking fund in June and December. The reduction of the capital outstanding permits of the extinguishment of the debit to capital account of £3,870, and the writing down of the capital expenditure by £7,330.

Agency.—Girdlestone and Co., of 16, Davies-street, Berkeley-square, London, W., have been appointed sole London agents for Messrs. J. P. Hall and Co., of Blackriding Ironworks, Oldham, for the sale of their specialities in dynamos, engines, turbines, projectors, etc

BRITISH ASSOCIATION PAPERS.

We have made this week's issue almost entirely a report of British Association papers in order to get rid of all recollections of that meeting as far as possible at the earliest moment. Our readers will be able to judge of the merits of the papers, and no doubt will pick up crumbs of information here and there. It is somewhat unsatisfactory to know that several papers on electrical topics were unread for want of time, and the more so, as some papers were undoubtedly given too much time. Indeed, the whole of the sections seem a little unbusinesslike in this way. A paper read early in the day too often is discussed for a length of time out of all proportion to its value. Our experience—if it is worth recording—is that, on the whole, the discussions on the papers were tame and unprofitable. In 90 per cent. of cases the speakers did not speak to the papers at all, but launched out into some phase of the question wholly unconnected with the paper, and generally without possibility of even the remotest connection with the subject-scope of the paper. This, with all due diffidence in saying it, was due entirely to the various presidents. The difficulty of presiding over a sectional meeting is great, and the difficulties are made greater by laxity of authors and of organisation. If a president is to keep the discussion within touch of the subject-matter of a paper, he must know the subject-matter of the paper; hence he should at any rate be provided with a pretty full abstract, if not with a complete copy of the paper. Under present conditions it is absolutely impossible for the president to become perfectly acquainted with the scope of the paper while it is being read. In the anxiety of each section to get a sufficiency of papers it too often happens that in the end too many are obtained, some of which could have been better unwritten, as they may cause better papers to be thrown out or given in pantomime. Fewer and better papers and real discussions should be the cry, if the British Association is to continue to exist. We do not know whether a plethora of papers in Section A led to the discussion on "Magnetic Units" being postponed to the morning of the last day of the meeting, but such postponement was fatal to real discussion. The set speakers had their say, and that was about all. Many men interested in the question were either absent or refrained from taking part in a discussion that could not possibly lead to anything practical. A catch vote at the end of a meeting in a section where probably fully one-half the few hearers had neither part nor parcel in the question, is not a good way to induce English or foreign writers to accept the suggestion of new units. Again, we might ask if Section A is *the* section to put even the suggestion to the vote? As we understand it, Section A is composed largely of doctrinaires—largely of students who sit at the feet of learned Gamaliels, and have no views save those of the Gamaliels at whose feet they sit — while Section G is composed far more largely of practical men—men who have had experience in carrying out large works and of organising factories. It is just

Digitized by Google

possible that the members of Section G could say, We do in practice feel the need of this or that unit, of this or that definition; while all that Section A can say is, You ought to feel the need of it. In our view, then, the suggestion of an extension or change of units should not be the work of one section, but the combined work of all the sections which are interested, theoretically or practically, in the subject. Section A should have combined with Sections C and G in this matter. We are not here entering upon a discussion of the desirability or the undesirability of new units, new substantives, or new definitions. We are simply concerned with the question whether, as carried out under the auspices of Section A at Ipswich, the matter brought forward by Dr. Lodge is advanced. Further, we are somewhat of the opinion that the British Association has lost the lead in this matter. Several international congresses have been held and international agreements made. It seems, then, that if extensions are to come, the extensions should be the result of further international agreement before being recommended for adoption. There would be no objection, perhaps, to the British Association recommending certain new departures to the next international congress, whenever and wherever that may be. If, as one or two speakers suggested, the whole of the present system has to be thrown overboard sooner or later, what is the use of tinkering? These academic discussions may or may not add to the reputation of individuals, but, like a good many other things of an academic nature, they have no permanent value.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

MUNICIPAL ELECTRICAL ENGINEERS.

SIR,—The first few opening lines of the leading article in your current issue on the above subject led me to anticipate some little support from your journal for our newly-formed association, especially when I had reached the point where you claim to have previously advocated the formation of such an association.

Your argument from that point, however, renders the title an absolute misnomer, for the remainder of the article savours very strongly of personal attack, notwithstanding the "saving clause" at the end.

Let me say at once, as one of the municipal electrical engineers, that I consider this portion of your article most inopportune. You have entirely overlooked the fact that the secretary is appointed *pro tem*, and whether or no one may agree with you that as a permanent appointment the official should be above suspicion and entirely unconnected with trade, the personalities introduced into your argument are beside the point, and are not only to be regretted, but condemned. In the case to which you allude no error has been committed, as you surmise. On the contrary, the committee were unanimous that no other person could so well serve the immediate interests of the association as the gentleman appointed. In this decision, although as yet I have had nothing to do with the association, nor was present at the meeting, I entirely concur; and the gentleman in question, in accepting the appointment, gives an advantage to the association which is of the utmost importance in this stage of its existence. Again, your insinuating assumptions of child-like innocence, on the one hand, and of utter unscrupulousness, on the other hand, are so painfully hypercritical as to disgust the readers for whose edification (?) it is intended. For instance, I have yet to know the committee and the member of it who could possibly make the engineer's life a burden, let alone a shame, because he belonged to an association whose secretary was connected with some trade concern. If an engineer, municipal or otherwise, were not perfectly straight in his business dealings his life would be a burden and a shame under any circumstances, but the direful possibility you conjure up is, thank goodness, no more than a grossly ludicrous idea.

Are you aware that municipal electrical engineers do not conduct their business, nor entirely exist, to please individual members of their committees? There are higher considerations by far which regulate their actions and assign to them their value, but of such things your article writer appears to be an entire stranger.

Municipal electrical engineers must feel deeply indebted to your opinion of them, and will, I am sure, anticipate further help of a similarly disinterested character.

In conclusion, I do not think municipal electrical engineers "less used to the ways of this wicked world" than are men of other professions, or they would be taking your article as written purely in the interest of themselves and their association.—Yours, etc., ALFD. H. GIBBINGS.

[This letter of Mr. Gibbings's is delightful. It shows our article touched a sore, and has caused some wincing. Perhaps Mr Gibbings will enlighten the public, and especially the councils which engage and employ electrical engineers, how it comes that a man wholly unconnected with municipal work, except as a commercial traveller to sell goods, comes to be mixed up officially with the formation of a municipal electrical engineers' association? When we find a bank manager mixed up with the formation of what purports to be an important company, it requires little foresight to know his reasons for being so mixed up. Does Mr. Gibbings imagine the "wicked world" is for a moment misled by the term "secretary *pro tem.*"? It wants to know, you know, what business an outsider has in the councils at all, and why he who cannot well know the "higher considerations by far which regulate their actions and assigns to them their value," because he is an outsider and not an insider, is to formulate and guide the actions of the embryo society. Mr. Gibbings's letter shows that his knowledge of the ways of this wicked world is comparatively small. When he has had a few more years' experience of the funny doings of councils and committees he will probably be able to tell another tale. But enough of this banter. Mr. Gibbings may think what he pleases, but the fact remains that an outsider has been appointed—*pro tem.*, if you like—and such appointment was an error. As for ourselves, we have no personal bias one way or the other. We know there is a deep-rooted objection among municipal electrical engineers to the course pursued, and we have given effect to the views of a large number of such engineers.—ED. *E. E.*]

SIR,—With reference to your leader upon "Municipal Electrical Engineers," published in your number of September 20, 1895, as you remark, the subjects that interest the central-station engineers and their assistants are such as can only be discussed properly by members having no trade connections whatever, and all the members must be free from any taint of being connected with any house in the trade; but there would, in my opinion, be no objection to any officers of a technical paper becoming members of such a society.

The gentleman to whom you allude, in conjunction with myself, discussed the question, and the matters above referred to were fully appreciated by us at the time; but the question of starting such a society required someone in a position to feel the pulse of my brother engineers, and this thankless task was accepted by our friend under discussion, but with the knowledge that when the society was under way, he would retire as a matter of course. It is very exceptional to find one of our kidney capable of sparing the time to promote in this manner such a society.

For the sake of the engineers who are not yet aware of the proposals that are in the air, and also to elicit an expression of opinion upon the matter, I will briefly state the principal features discussed so far, and which have met with cordial support:

1. That the society shall meet during the year a given

Digitized by Google

number of times to be determined upon, on each occasion at some town or district, with the idea of viewing an electricity works.

2. That the chairman shall be the chief engineer or manager of the electricity works to be visited on such occasions.

3. That a dinner shall wind up the day, for which each member shall contribute his share of the expenses—the chairman being entertained by the remainder of the members.

4. Discussion to be absolutely under the control of the chairman.

5. No set papers, but criticisms to be made, if possible, upon the works lately under inspection.

6. The society to be empowered to order the printing of any details of interest and to circulate them amongst its members, orders for such to be carried by vote at one of such meetings.

There are a lot of other questions, of course, that require discussion, but such questions should be left over until a meeting of the society took place.

With a view of clearing the ground to a certain extent, and also to bring the matter to a head, I suggest that a committee of, say, four members of our profession, be chosen to confer together, and to issue the necessary circulars, with a view of bringing the matter under the notice of all our brothers, and to accept and appoint as members *pro tem.* all chief engineers or managers who apply for membership. When the further details as to subscriptions and mode of procedure shall be determined upon, then all applications for membership from assistants shall be taken into consideration. Any *pro tem.* member not withdrawing at this time shall be considered a member, and to be liable to the subscription arranged to be paid.

It will be seen that, owing to the proposed arrangements for the society's meetings, etc., the subscription should be merely nominal, as any expenditure will be voted upon by all the members at their meetings before the dinner, as then the business will not be unnecessarily delayed. The expenditure in the case will be entirely under the control of the members.

I hope, Sir, that this question will receive the support from all my brother-workers that I believe the subject merits, and that the discussion, if any, that may arise will promote the object in view.

I shall be pleased to receive letters from any electricity works managers or chief engineers, with any suggestions they would like to make upon the subject, and whom they, in their opinion, think would be the best four members, being all engineers or managers of electricity works, who would be likely to meet their views as regards the formation of the society; I will then analyse the names, and will write to those four receiving the greatest support, and try and arrange a meeting to take place as soon as possible.

I have taken the initiative in this matter well knowing that many members of our profession are much more competent to deal with it than I am. At the same time I shall be only too pleased to do all in my power to advance its prospects.—Yours, etc., J. E. STEWART.

Corporation Electric Lighting Station, Full-street,
Derby, September 25, 1895.

[Mr. Stewart having taken a keen interest in this matter, why not, instead of waiting for letters, take the further action and ask, say, Messrs. Baynes, Hesketh, and Talbot, as men of a representative character, to confer with him, and prepare a circular to be sent to all municipal electrical engineers.—ED. *E. E.*]

SOME USES OF CURVES IN ELECTRICAL PRACTICE.

BY H. H. SIMMONS, A.I.E.E.

(Continued from page 243.)

A further use for the straight line O I is at once obvious. If we have a dynamo whose characteristic is given by the curve V, in Fig. 13, we can very readily find what the dynamo will do when working on a given resistance by drawing such a line, O I, as will represent that resistance. The effect of any change in resistance is equally quickly seen.

Being in possession of the characteristic curve, O V, we can draw lines to represent resistances of, say, 3·5, 4, and 5 ohms—viz., I_0, I_1, and I_2—and we find these cut the curve at the points P_0, etc., respectively, showing that when the dynamo is working on these resistances it will give 42 volts 12 amperes, 45 volts 11·25 amperes, and 50 volts 10 amperes respectively. The lines I_3 and I_5 show that we can get 56 volts with a current of either 4·2 or 8·2 amperes, according as the resistance is either 13·3 or 6·82 ohms. The maximum of 59 volts is obtained on a resistance of 9·83 ohms with a current of six amperes.

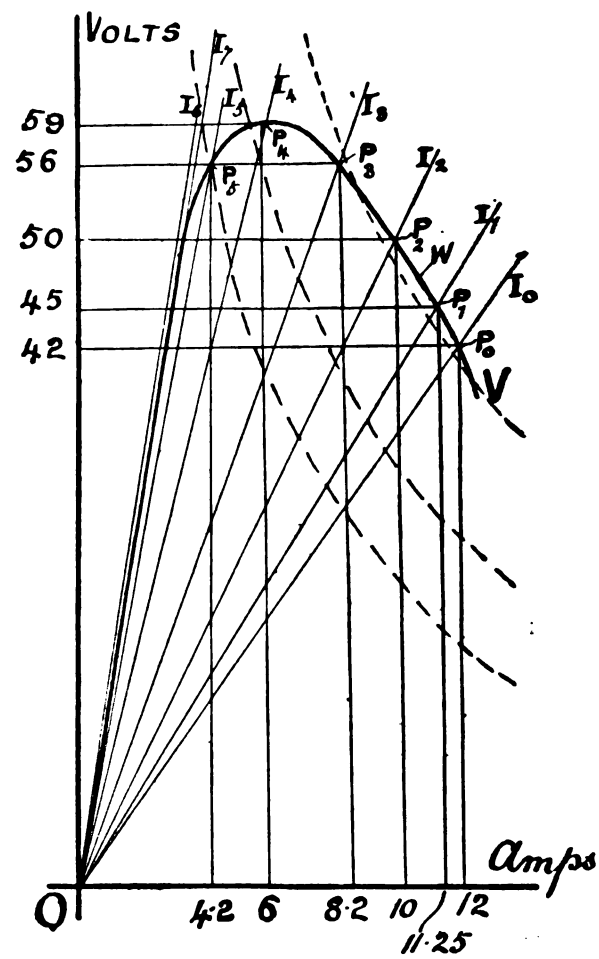

FIG. 13.

I_7 is seen as a straight line coinciding with a considerable length of the curve; this shows the resistance represented—viz., 15·5 ohms—to be an unsuitable one, or rather that the dynamo will not work well on it; the conditions being obviously very unstable when any current and voltage, from nothing up to 3·2 amperes at 49·5 volts, can be obtained from the machine on this one resistance. Also, any drop in speed would have the effect of stopping all current in the circuit. This is seen by reference to I_6, which represents a resistance of 14 ohms and which lies right outside the curve, not cutting it in any point at all. Now any decrease in speed lowers the whole characteristic, for with a given current flowing in the magnet coils and armature the internal E.M.F. will be directly proportional to the speed, since the field resulting from the magnets and armature will be the same for the same current. To obtain a new characteristic from the old for a new speed, therefore, we have only at every point to add the volts wasted in the machine to the terminal volts at the first speed, and reduce this total internal E.M.F. in proportion to the speeds, and then again deduct the volts used in the machine. This will give us the terminal voltage at every point for the new speed: If the speed be less, the voltage at every current value will also be less, and this will throw I_7 into the same condition as I_6—viz., right outside the curve. From this we see that if we are working on a resistance at the position of I_5 we run the risk, in the

Digitized by Google

event of a drop in speed, of having a total stoppage of current in the circuit until the speed again rises.

The dotted curves are curves of constant horse-power—*i.e.*, the product of the volts and amperes at any point or all points on one of these curves is the same. The point of maximum power is evidently about the region of the point W.

(To be continued.)

NOTES ON A RECENT DEATH FROM LIGHTNING STROKE AT SHOEBURYNESS, ESSEX.

BY DAVID T. KEY, M.R.C.S. (ENG.), L.S A., SURGEON-CAPTAIN VOLUNTEER MEDICAL STAFF.

During the recent meeting of the National Artillery Association at Shoeburyness, where I was doing duty as camp surgeon, the following fatality occurred. On Tuesday, August 6, 1895, at 6.50 p.m., a man, whilst walking with a female companion along the footpath leading from South Shoebury to Shoeburyness railway station, was struck by lightning and killed instantly. He was a London cab-driver, single, aged 30, had been in the army, and was an army reserve man at the time of his death. The footpath is about 6ft. in width, having on one side a shallow ditch and a row of tall old elm trees, and on the other an iron railing about 5ft. high, the rails forming a row of pointed spikes 6in. long above a horizontal bar. The tree nearest to the deceased was the last of the row. It was to the man's left hand, and the woman was between him and the railings They were walking. There had been no rain for about three-quarters of an hour. Deceased was perfectly dry. I saw him within four minutes of his death. He had fallen on his face diagonally across the path, with his head towards the tree. His face was livid and suffused with blood. His eyes were closed; yellow mucus was exuding. He was quite dead, so I had him placed on a small ladder and removed at once, as there were still frequent flashes of lightning, a possible source of danger to onlookers. There was probably a rise of temperature, for I observed the body was very warm to the touch, and there was a very powerful smell of burnt hair and flesh. His companion was thrown against the railings, but did not fall. She was able to answer my questions, but was very pale. She said she felt heat on the left side of her face. Her left ear was filled with *debris* of hair. On examining the body at 8.30 a.m. next morning, in conjunction with Surgeon-Colonel Coats, A M.S., garrison surgeon, the body was found to be well nourished, muscular, and well developed. Rigor mortis was well marked. On examining the head the point of probable entrance of the electric fluid was found to be at the vertex, almost central; slightly to the left of the central line showed an oval excavation in the hair about 1in. No wound was apparent. The hair was all singed short over the left side of the head. The left eye brow, eyelashes, and left side of the moustache were practically gone. Fluid was escaping from the left ear. On tracing the burns on the left cheek and under the left lower jaw several large ones were found on the left thorax and sternum; thence centrally over the abdomen. The hair of the pubes was all singed short; the scrotum was swollen and livid; thence along the inner side of the right thigh and calf over the internal malleolus, the point of exit of fluid being at the inner and central point of the right heel. The burns were of various sizes and interrupted, the largest being that on the sternum, about 1½in. in diameter. The surface of the burns was dried. The epidermis was entirely destroyed and gone. On examining the clothing, the hat was found to be in small shreds, but the coat and waistcoat were very slightly damaged A blue woollen jersey was not much damaged. The shirt (grey flannel) was split in the same direction as the burns, and a merino undervest next the skin was split in the line of the burns two-thirds from above downwards—the edges of this crumbled when handled, but were not charred black. There was a hole through the watch pocket. The trousers were split into long vertical ribbons in both legs, but more especially along the line of burns. The right pocket was blown to shreds (there had been about 14s. silver money in this, which was picked up at the time of removing the body). The drawers were very much torn. The boots were of the front lace-up pattern, the soles and heels of which were entire, but some brass nails had started in the sole of the right boot. Half of the inner uppers of each boot was entirely gone; also the metal eyelet holes. The right boot was blown off the foot entirely at the time of the accident. The collar and cuffs were in shreds. The necktie (a bow) was split in two in the middle. The tree showed a spiral interrupted track of the lightning, the bark being broken off The lightning apparently left the tree about 10ft. from the ground, and four days later I observed just below this point one small thin twig (only) about 2ft. long, the leaves on which had withered. This would correspond to a point about 18in. above the man's head. The following articles were found on the deceased: money—besides the silver—in left-hand breast coat pocket, inside, thirty-seven sovereigns and twenty-eight half-sovereigns in a common leather jaw-opening purse which had a metal rim and closed by two small knobs. The coins (nearly all) were wrapped in separate pieces of thin paper and the purse tied up in a handkerchief, In the waistcoat pocket, on the right side, a silver match-box containing two unignited wax matches and silver Geneva watch (no chain) were found. There was also a gold ring on one of the fingers. A pocket knife was also found. With regard to the condition of the coins, two half-sovereigns were slightly fused and adhering together; one sovereign was partially fused on one side as though a splash of metal had been thrown on it. Many more of the gold coins showed traces of fusion of the milling of the edges only; several of the silver coins also showed similar fusion of the edges The watch (open-faced) had a hole ¼in in diameter through the outer case by the hinge, and on opening this there was a splash of metal on the rim of the dome, and another on the bow. The watch had stopped at 6.55, but could be wound up. The steel hair-spring would not recoil, as probably it had lost its temper. The watch glass was broken. The ring and knife showed nothing. The metal rim of the purse had a small point of fusion on one side—inside – and the purse also had a hole through one side of the leather.

It would be interesting to know whether the base of the skull was fractured, as fluid was seen issuing from the left ear and not from the right one; whether from the apparent direction of the electric fluid in the line of the left pneumogastric nerve this would sooner affect the heart's stoppage; and, also, whether the deceased received the whole of the discharge or whether any passed over the woman's head to the pointed railings. There can be but little doubt that the gold attracted the lightning. Had deceased not been immediately under the tree his head would probably not have been struck first, but the gold would have received the discharge direct. The path of the lightning also should be noted—from the largest burn on the *left* chest (close to the heart's apex) through the watch pocket to the gold, thence to the *right* trousers pocket, touching the watch on its way, and giving a slight radiation towards the match-box. A violent explosive force was expended in the right trousers pocket so as to blow it to pieces and throw the silver coins towards and under the railings, where most of them were picked up at the time of removing the body. The next greatest force was expended in the right boot so as to blow away the adjacent inner sides of both boots. I gave evidence at the inquest, but the coroner would not give me leave to make a post-mortem examination, which no doubt would have added still more to what has been to me a case of great interest.—*The Lancet.*

TELEGRAPH LEARNERS' INSTRUMENTS.

The postal telegraph authorities and the railway companies all over the country are constantly requiring recruits for the manipulation of telegraph instruments. To become a telegraph operator one need know nothing of electricity, though of course such knowledge is not to be despised. To work the Morse instrument it is necessary to be able to manipulate the "tapper key" with facility and speed, tapping out the dots and dashes which constitute the symbols representing letters and words. Another class of instrument is the single-needle telegraph, Fig. 2, in which the depression of the right or left pedal moves the needle to one side or the other: a movement of

Digitized by Google

the needle to the left or right corresponding respectively with the dot and the dash of the Morse instrument. To attain speed and certainty in signalling requires a great deal of practice, and the necessity arises for instruments whereon one can acquire this facility at home.

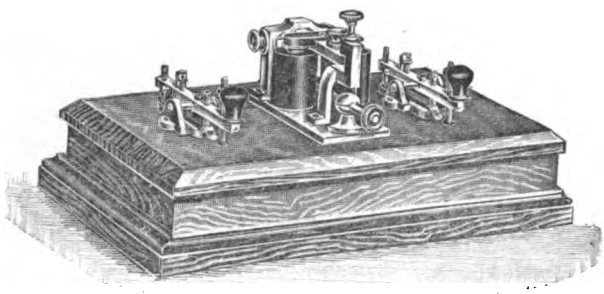

FIG. 1.

The instruments of Mr. Morris, of King's Lynn, fulfil the requirements of learners in a very effective manner. The instruments correspond outwardly in every respect with the actual apparatus as used by the Postal Telegraphs; but they are dummies so far as electrical action is concerned, the working being purely mechanical. The keys of the Morse instrument (Fig. 1) are connected with the armature of the sounder, and the pedals of the single-needle instrument with the needles, by very ingenious and simple arrangements of levers. The Morse instrument shown in Fig. 1 enables two persons to practise at the same time on the same sounder, one signalling to the other and *vice versâ*. For the same purpose the single-needle instrument (Fig. 2) has another dial and pair of pedals at the back. A simpler form of Morse instrument is provided with one key only.

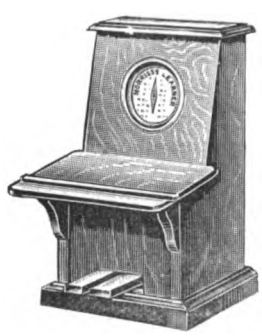

FIG. 2.

The doing away with all electrical fitting, and the absence of batteries, enables these instruments to be turned out at low prices, which are insignificant when compared with their educational value to the aspiring telegraph operator.

W. PERREN MAYCOCK, M.I.E.E.

[If we recollect rightly, some 15 years ago or so Mr. Volk, of Brighton, put upon the market, not dummy instruments, but workable needle instruments, eminently suitable for telegraphic learners. We could never understand why the sale of these instruments, or, rather, the production of these instruments, was dropped. The sale, we believe, was very good. Probably Mr. Volk sold them at too cheap a rate, and found work in other directions paid better.—ED. *E. E.*] .

PROBABLE PROJECTION LIGHTNING FLASHES.*

BY ERIC STUART BRUCE, M.A. (OXON), FELLOW OF THE ROYAL METEOROLOGICAL SOCIETY.

The revelations of the self-taken photographs of lightning flashes have of recent years caused us to modify our ideas concerning the appearance of lightning, and the varied forms displayed foretell that a future classification will be no easy task. The object of the present paper is to suggest the possibility of a kind of flash which may be called a projection flash, the existence of which species would by no means tend to make the work of classifying simpler.

When we view the effects of a distant thunderstorm over a large area such as the surface of the sea, sometimes a bank of clouds, sometimes the whole horizon, appears lit up with a sheet of light. This species of lightning we call sheet lightning, and we may compare this effect to my flashing this incandescent electric lamp, so that its flashes are reflected by this white screen. Though on the reflecting surface of clouds we can see no form of flash, yet we know that the sheet of light is made up of countless images of the lightning flash superimposed one upon the other so that we cannot distinguish them. So also when we flash this incandescant lamp we know that the light reflected from the screen is made up of a number of images of the white-hot carbon filament of the incandescent electric lamp. This is seen to be the case when I limit the space through which the rays of light pass from the incandescent carbon to a small orifice in an otherwise opaque screen. Then there appears an inverted image of a white-hot horseshoe of carbon on the screen—we call it the *projection* of the image of the incandescent carbon filament.

It seems obvious that in nature there must often be an obstruction between the lightning flash and the reflecting clouds, in the form of a cloud that has a small opening in it. This condition of cloud perforation is frequently seen. On the screen I throw a rough sketch of a cloud with four perforations, as seen from my balcony on Campden-hill, June 14, 1893. When there is a cloud with a sufficiently small opening in it, between the flash and reflecting clouds, the latter being in an adequate position, on the clouds which otherwise would have been merely illuminated by sheet lightning there will appear the optical projection of a lightning flash.

When the projection of an incandescent lamp falls upon a level surface, we obtain a perfect image of the white-hot filament. When, however, I cause the screen to become suddenly irregular, we obtain a distorted image of the filament on the uneven surface. And so in nature, if the surface of clouds upon which the projection of the lightning flash falls is quite even, we shall have a perfect reproduction of the lightning flash, save that it is inverted and to some extent dulled in brilliancy. If, however, as would often be the case, the surface of the clouds is irregular, the projection of the flash will take the shape of the irregular surface, and there will be presented a flash very different from the original.

On the screen I show a photograph of that type of flash which is called "streaming" in the report of the Thunderstorm Committee of the Royal Meteorological Society, drawn up by Mr. Abercromby (*Quarterly Journal*, July, 1888). To quote Mr. Abercromby's words, "it is a plain, broad, rather smooth streak of light." I will now project this flash on some model clouds of the cumulus type, and you see its appearance is altered, being no longer the smooth streak of light, but what might be called a zigzag flash with long angles. It is something rather like what has been often represented by painters in pictures where lightning appears, which leads one to think they may sometimes have taken projection flashes as their models perhaps because this form of flash would not dazzle the eye as does the real discharge.

It must, however, be borne in mind that Turner, in his storms, painted lightning flashes very like those registered on the photographic plate. In this print of Turner's "Bass Rock," the lightning flash closely resembles some of the photographs. It should also be mentioned that Mr. Ruskin, in "Modern Painters," when criticising Turner's "Stonehenge," describes the lightning in that picture as "the white lightning, not as it is drawn by less observant or less capable painters in zigzag fortifications, but in its own dreadful irregularities of streaming fire."

When travelling in Switzerland about three years ago, the train was passing through a valley while there was a severe thunderstorm in progress. The valley was filled with wreaths of mist, forming an uneven surface; suddenly there appeared in the midst a very zigzagged flash of lightning, seemingly quite close to the window of my carriage. It was not of that overwhelming brilliancy that would have been expected of it if it had been the electric discharge itself at such very near quarters, but was dulled so that I could see the form without my eyes being in the least dazzled, and I felt very inclined to think this was a projection flash.

* Paper read at the meeting of the British Association at Ipswich.

Digitized by Google

If projection lightning flashes occur in nature as often as I am led to think is the case, it becomes a question whether the photographic plate can register the projection flash. If it does, we may be somewhat misled in our description of the form of the lightning flashes depicted on the plate, some being perhaps, not the original, but its distortion.

There is one more point concerning the projection flash which seems worthy of notice. If there are more openings than one in the cloud through which the rays of light pass from the flash, there will necessarily be a reduplication of the flashes giving a multiple effect. To represent a lightning flash, I now have a piece of platinum wire made white hot by the electric current. Between this and the screen I place a sheet of cardboard. I now make one hole in the cardboard, and there is one image of the lightning flash on the screen. I make a second, and there is another image, and as I continue to perforate the cardboard I get a corresponding number of images—perhaps those multiple effects we so often see explained by there being several openings in the cloud between the flash and the receiving surface.

MEMORANDUM ON THE BRITISH ASSOCIATION SCREW GAUGE FOR SMALL SCREWS.*

BY R. E. CROMPTON, M.I.C.E., PRES.I.E.E.

As a result of the two reports presented by the committee appointed by the British Association to design a standard screw gauge for small screws, a large number of users, including H.M. Post Office, have adopted them. In 1890 the London Chamber of Commerce appointed a committee to forward the question of making the British Association screw gauge universal among electrical manufacturers, and a circular was sent round to the entire electrical manufacturing trade, with the result that with hardly any exceptions the whole trade promised to adopt the screws, and thus ensure the extremely desirable result of making all the small screws used in electrical apparatus interchangeable. It is, however, much to be regretted that a considerable number of users of small screws (the principal offenders having their works in Birmingham) are still using other gauges, and thus complete uniformity has not been obtained up to the present time. One great difficulty in this matter has been that of obtaining standard gauges which could be referred to in specifications or orders for such screws. Wherever it is desired that the screws should be thoroughly interchangeable it is necessary in such specifications to have a paragraph somewhat as follows:

Testing.—Each box of screws will be tested as follows: A handful of one dozen screws will be selected at random from each box; these will be tested both as to the screw portion and the plain portion of the shank by being respectively screwed or pressed through the corresponding maximum and minimum gauge holes in the standard plates supplied on loan with the order, and which must be returned with the finished screws. Any screw which cannot be screwed or pressed by hand into the maximum female gauge, or which can be screwed or pressed by hand without force into the minimum gauge, will be rejected. If more than one screw in each dozen thus tested is so rejected, the whole box will be returned to the contractors.

Four years ago I found it necessary to have standard plates made for the purpose of ordering screws to the above specification. I had a number of such plates prepared, but found the very greatest difficulty in getting them made so that they would fulfil their required duty, the makers giving as an excuse that there was no standard B.A. gauge then existing to which they could refer. This difficulty can only be removed by a complete set of standards being made and deposited either with the Board of Trade or at the Society of Arts, or with a similar central institution; and it is highly desirable that the British Association should either call together the surviving members of the original committee or form a new committee to consider the question of making up these standard gauges and deciding on the place where they are to be deposited.

One question for the committee would be the requisite allowance of clearance between the absolute diameters of the various sizes as laid down in the report of the committee and the sizes of the maximum and minimum gauge holes in the gauge plates. Another point of importance in order to make this standard screw gauge universal would be the issue of a short descriptive report, with illustrations, giving the sizes, clearances in gauge plates, best method of reproduction on English lathes of these screws, together with a few sectional drawings showing the shape of thread, rounding off, etc.

DO VERTICAL (EARTH-AIR) ELECTRICAL CURRENTS EXIST IN THE UNITED KINGDOM?*

BY A. W. RUCKER, F.R.S.

In a paper by Dr. Adolph Schmidt read before Section A of the British Association at Oxford, the author stated that he had expanded the components of the earth's magnetic force in series, and had deduced expressions, two of which give the magnetic potential on the surface of the earth in so far as it depends on (1) internal and (2) external forces. "The third series represents that part of the magnetic forces which cannot be expressed in terms of a potential, but must be due to electric currents traversing the earth's surface." The author concludes that such currents amount "on the average to about 0·1 ampere per square kilometre." It appeared, therefore, desirable that this conclusion, drawn from the magnetic state of the earth as a whole, should be tested by means of those portions which have been most fully studied.

The test to be applied is whether the line integral of the magnetic force taken round a re-entrant circuit is or is not a vanishing quantity. The irregular form of the United Kingdom makes the application of this test more difficult than it would otherwise be, but as two detailed surveys of Great Britain and Ireland have been carried out by Dr. Thorpe and myself for the epochs 1886 and 1891 respectively, the data at our disposal are so numerous that I thought it worth while to undertake the enquiry. The actual work of calculation has been carried out almost entirely by two of my students—Messrs. Kay and Whalley. My best thanks are due to them for the care and skill they have displayed. Two circuits, called the α and β circuits respectively, were selected, bounded by the following lines:

(α) Long. 2° W., Lat. 58° N.; Long. 7° W., Lat. 52° N.
(β) Long. 1° W., Lat. 55° N.; Long. 9° W., Lat. 52° N.

The work done by a unit magnetic pole on traversing these circuits was calculated for the epoch 1886·0 by means of the terrestrial lines found for that date, and also for the epoch 1891·0 by means (1) of the same lines when due allowance was made for the secular change, and (2) of the independent set of lines found by aid of the later survey. The magnitudes of the hypothetical currents deduced from these calculations were very small, and those for the later epoch were of opposite signs, according as they were calculated from the earlier or the later survey.

The same calculation was made for two other circuits, one (γ) in Great Britain and one (δ) in Ireland; but instead of using the calculated terrestrial lines, the true values of the forces and declinations were employed, as deduced from the nearest stations. The great local disturbances in Antrim interfered with the value of the Irish circuit. The following table gives the results in amperes per square kilometre obtained from circuits α and β by the terrestrial lines for 1886·0, and also by the mean terrestrial lines for 1891·0, which occupy the mean position between those given by the two independent surveys, and also for circuit (γ).

	Circuit.		
	α.	β.	γ.
1886·0	−0·026	−0·004	—
1891·0	+0·001	−0·005	—
1891·0	—	—	−0·008

From these we may conclude that there is not in the United Kingdom a vertical current amounting on the average to 0·1 ampere per square kilometre. There may possibly be a current of about a tenth or a twentieth of that amount, and, if so, the signs show that it probably flows from air to earth, but on account both of the smallness of the results and of the discrepancy between the values obtained for 1891 by two independent calculations, we cannot assert that such a current actually exists.

The calculations do not disprove Dr. Schmidt's hypothesis, as we cannot argue from the condition of a small portion of the earth's surface to that of the whole. The most that can be said is that no evidence in favour of the existence of vertical currents can be drawn from one district which has been very minutely surveyed.

THE FIELD TELEGRAPH IN CHITRAL *

BY P. V. LUKE, DEPUTY DIRECTOR-GENERAL OF INDIAN TELEGRAPHS.

The field telegraph required for the army in India, for the many small expeditions in which it is so often engaged, is furnished by the civil telegraph department. The department must be ready, therefore, at all times to meet any demands made upon it. A suitable equipment has been designed and a stock is kept at convenient depôts at various points on the frontier; this enables an immediate start to be made with the construction of the field telegraph in any operations, while for prolonged operations the whole resource of the civil telegraph department can be made available. All the equipment is arranged for "pack" carriage; the maximum weight of any one package is fixed at 80lb. (one half the load a mule will carry). After every campaign a full report is sent in of the working, and any defects brought to light are dealt with at once. The receiving instrument used is a sounder similar to the one used throughout India, only reduced in size. It is fitted on a baseboard with a small Siemens relay and a key with connections so arranged that it can either be worked "direct" or as a "local" A perfect portable battery has still to be designed; at present the so-called "dry" pattern is used. The unit of office equipment or total needed for one field office which includes tents, etc., comprises seven mule loads, but it can be compressed to four loads if necessary for an emergency and for temporary work. Telephone apparatus is always included. The line wire employed is iron wire weighing 300lb. and 150lb. per mile and stranded hard copper wire weighing 80lb. per mile; light field cable is used for certain purposes. For poles, where possible, the resources of the country passed through are utilised, but for bare country iron poles are carried. They are tubular sheet iron in three pieces, fitting telescopically; the total height is 18ft., and weight 40lb., the packages being 5ft. long. At 20 to the mile they will carry three wires one in a cap, the other two on insulators. The rate of construction depends on the transport, labour, and character of country. In the Waziristan campaign a single wire line was put up at rate of nine miles a day for five consecutive days Special arrangements for rapid repair are always made; for this purpose it is necessary to have a telegraph office at every 10 miles with a trained line staff. For the signalling staff trained British soldiers are mainly used; these men are employed at other times at different telegraph offices throughout the country, usually where their regiments are quartered. The field telegraph forms a distinct department in the field, under a civilian telegraph officer appointed by the Director-General of Telegraphs, and taking his orders from the chief of the staff.

Information of the siege of Chitral came from Gilgit over the line which was only completed in 1894. This line is carried over two passes, one 11,600ft., the other 13 500ft. above sea level, where the snow lies from 10ft. to 18ft., yet it worked well all through the winter. The staff at the observation stations close to these passes are entirely cut off from the rest of the world except by wire for seven months in the year. The place selected as the base of operations was Holi Mardan. Best material for a two wire 200-mile line with 20 offices was at once collected, together with the necessary staff for constructing and working. From this point the wire was pushed on as fast as possible, and a field office was opened on the Walakand Pass a few hours after the battle At first it was a single-wire line, but it was afterwards made a three-wire line as far as the Swat Valley, then a two-wire to Dir, and finally one-wire to Chitral Fort. Great difficulties with transport occurred at Lowari Pass owing to the pass not being passable for camels; but for this the wire would have been into Chitral by May 12; as it was, it did not reach there till midnight of the 17th On account of the scarcity of timber it was necessary to use iron poles very extensively; at the Lowari Pass, however, there is a fine pine forest; wooden poles were afterwards used. After May, cutting the wood became very frequent and even very difficult to stop After the start the traffic, which was exceedingly heavy, was dealt with with but little delay. In April 24,370 and in May 58,935 messages were dealt with, and their length was much above the average Shortly after the Malakand fight by clearing the line right through to Simla the Commander-in-Chief was enabled to talk direct to General Low, and in spite of heavy rains at the time the communication was excellent To give some notion of what was accomplished it may be stated that a telegram dated Chitral Fort, May 19, was published in the London papers of the same date.

The telegraph department also assists in defending camps by running wires round the camp, so arranged that an alarm is at once given by the ringing of a bell in the quarter guard should a night surprise be attempted, and in many other ways much aids and assists the military authorities. Medals and decorations are given to the staff at the conclusion of the campaign.

* Abstract of paper read at the meeting of the British Association at Ipswich.

THE CORPORATION OF CORK.

The following is the report of the Electric Lighting Committee to the Council:

Reference from Council, July 5, 1895.—To consider and report on the following—viz.: Notice from Hanrahan and Co., solicitors for the Cork Gas Consumers' Company, of their intention to apply to the Board of Trade for a provisional order to authorise them to supply electric energy within the city of Cork, under the Electric Lighting Acts, 1882 and 1888, and requesting that a meeting of the Corporation may be convened to consider the matter. Like notice from R. A Atkins, Esq, J.P., on behalf of the Cork Electric Light and Power Company, Limited; and like notice from Edward Felton, of 35, Careysfort-avenue, Blackrock, co Dublin, on behalf of a company to be formed and known as the Electricity Supply Corporation of Ireland, Limited.

Your committee at their first meeting having resolved that in their opinion the time had come when electricity for public and private purposes should be provided in the city, whether by the Corporation or some other body duly authorised, considered it necessary, before proceeding to the consideration of the subject of reference, to ascertain from Dublin and other municipalities how far the local corporate bodies had undertaken the work of electricity supply, and with what results as to the public service and the advantage of private consumers, and more especially with regard to the financial results of such undertakings. Queries were accordingly addressed by the secretary of committees to some 50 local authorities throughout the United Kingdom, and the information so collected was embodied in a report which has already been printed and circulated amongst the members of Council

That the demand for electrical energy, whether for lighting or motive power, is everywhere increasing is amply demonstrated by that report, and private enterprise has already to some extent been called upon to satisfy the demand in this city. The order of reference to the committee shows that there are capitalists quite ready to embark in undertakings of this kind, even in Cork; but the first question to be considered in your committee's opinion is, whether the duty of supplying a public necessity of this nature should be allowed to fall into the hands of any but the municipal authority. The prevailing opinion throughout the kingdom appears to be that the control of electricity supply ought, like that of gas and water, to devolve upon the local governing body, and your committee feel disposed to adopt that view. The superiority of electric light over the other common illuminants is generally conceded; but the consideration which will probably weigh most with a body of the limited resources of the Corporation of Cork is, how far the benefits derived from its adoption would warrant the increased expenditure that would have to be faced In the other municipalities referred to, the experience of the local authorities has been somewhat diverse in this matter of financial results, owing, doubtless, to varying local conditions.

In most cases a pecuniary sacrifice has had to be made in the first year or two where the local authority had undertaken electricity supply for all purposes, but as the demand grows and capital expenditure diminishes the direct results become more satisfactory. In some places, favourably circumstanced and with good administration, an immediate financial benefit has accrued to the ratepayers but these cases are the exception. In the instance nearest home that of the Dublin Corporation, which now lights the principal public thoroughfares with electricity, besides supplying current also for private purposes, the financial results are summarised by the city accountant in one sentence, when he states that "the first year's revenue, if viewed in the light of an undertaking by a private company, would yield 4½ per cent on the capital invested." There are, however, indirect benefits which the introduction of electrical supply has secured in many places, such as the reduction in the price and the improvement in the quality of the gas supplied to the public, and it is at the same time noted as an almost universal experience that the consumption of gas has in those places increased rather than diminished

How far the administration of a new department of this kind, in the corporate service of this city, would be a success, is a question well worthy of consideration; but it has been suggested that, even if the Corporation were to delegate the work of electricity supply to a private company, under proper safeguards and conditions, the authority to provide the supply should primarily rest with the Corporation. Before, however, arriving at any definite conclusion, or making any specific recommendation on the subject, your committee find it necessary to obtain competent professional advice as to how far the area of advice ought to extend, what the reasonable probabilities might be as to expenditure and income in connection with such an undertaking, and other subsidiary considerations which ought to influence the Corporation in dealing with a project of such novelty and importance to them. In order, therefore, to be in a position to avail of such advantages as legislation has placed within your reach, should you so determine, and to be enabled to do so fortified with adequate scientific knowledge and practical experience, your committee for the present content themselves with recommending that the town clerk be instructed to convene a special meeting of Council for Friday, October 27 proximo [?], for the purpose of taking into consideration the notices already received from private companies of their intention to apply to the Board of Trade for provisional orders, and also to consider the expediency of the Corporation themselves applying for a provisional order authorising them to supply electrical energy within the district; and that for the purpose of enabling this committee to form a definite opinion on the latter subject, and to advise the Council as to what course they ought to adopt in the premises, the committee be authorised to employ a competent electrical engineer, of sufficient practical experience, to assist them in considering the whole subject and reporting thereon. All which your committee submit as their report, this 18th day of September, 1895.

JAMES L. BOGAN, Vice-Chairman.
D. F. GILTINAN, Secretary of Committees.

SOME LESSONS IN TELEPHONY.*

BY A. R. BENNETT, M.I.E.E.

(Concluded from page 321.)

On enquiring in what manner circumstances differ so gravely in the United Kingdom as to preclude the possibility of small towns and rural communities availing themselves of telephonic communication, it appears that, apart from the want of local control and competition, the inelasticity of the present system of tariffs, which was originally invented for towns, is much to blame. In towns distances are short, and subscribers, if the switchrooms are properly distributed, have seldom to pay more than the unit charge, but in country districts distances of several miles must often intervene between the subscriber and switchroom, and as the annual rental exacted increases rapidly with the distance the charges become piled up by the extra mileage beyond the means of the majority of the population. What is wanted is the application of the Austrian (which with some modifications has also been adopted in Luxemburg) system of tariffs, under which all subscribers, whatever their distance may be from the switchroom, are put on an equality as regards annual subscriptions, the only difference being made in the initial payment on joining the exchange, which varies with the length of line required, the object being to reimburse the owners of the exchange system once for all for the additional cost of the extra mileage. In Austria the annual subscription is the same for any distance up to 15 kilometres (9¼ miles). In Luxemburg the annual subscription, provided the distance of the subscriber from an existing route of wires is not greater than 1½ kilometres—which is seldom the case, so numerous are the lines—is always £3. 4s. per annum, which covers all charges for service and maintenance, and confers the right to talk all over the Grand Duchy, which measures 44 by 30 miles. If a subscriber is situated outside the free radius which surrounds every switchroom, he makes, on joining the exchange, an initial payment, designed to cover the cost of the line which intervenes between the free radius and his place. This is charged at the rate of £4 per kilometre only, and the payment may furthermore, if desired, be spread over five years. If located within the free radius, the subscription is simply £3. 4s. per annum without an initial payment. Comparisons are often instructive, and it will be interesting to examine the differences resulting from the application of this system and that which prevails at home.

In Luxemburg a subscriber located five miles (eight kilometres) from the boundary of a telephone area (provided he is not more than 1½ kilometres from an existing line) will pay :

A compensation for extra distance, £5 × £4 = £20 in one payment, or, if he chooses, divided into five annual payments of £4, and thereafter an annual subscription of £3. 4s. If 15 kilometres (9¼ miles) away he pays £15 × £4 = £60 down, or £12 for five successive years at his option, together with an annual subscription of £3. 4s. He may be taken to pay £15. 4s. for the first five years, and £3. 4s. per annum for all time thereafter. The British Post Office charge £14 per annum per mile, so that a subscriber five miles from a switchroom would be charged £70 per annum in perpetuity, while one 9¼ miles away would pay no less than £134 per annum. The National Telephone Company's charges would be more than this in the metropolitan area and less in the provinces, but always, as experience has amply proved, prohibitive.

The different results aimed at in the United Kingdom and in Luxemburg need, therefore, create no surprise. They are simply examples of cause and effect. It cannot be said that such rates as are applied in Luxemburg do not pay. Accounts and balance-sheets have recently been published† which prove that even lower charges are made remunerative by local companies and municipalities in Holland, Denmark, and Norway.

The telephonic development attained in the Aland Islands, the entire population of which numbers but 18,000, has been mentioned. What have we to show at home of a corresponding nature? The Isle of Man (population 55,608) has one exchange. The Isle of Wight (permanent population 78,672, which is much increased in summer), containing seven or eight flourishing towns, possesses no telephonic facilities whatsoever ; and the Channel Islands (population 92,234) are in equally bad case, although both Jersey and Guernsey are places in which a good telephone system would be of the utmost value, owing to the necessity the farmers are under, especially at certain seasons, of maintaining good communication with the ports, St. Helier's and St. Peter's. Exchanges in these towns alone would be next to useless : it is necessary to bring the outlying villages and scattered farmsteads into connection with them, and as this would necessitate many lines of from two to five miles in length, the existing tariff both of the Post Office and National Telephone Company are prohibitive and impracticable in a ludicrous degree. But an intelligent application of one or other of the Norwegian, Finnish, or Luxemburg methods would speedily cover the islands with telephone lines, and that with profit both to the servers and the served. The cases of Jersey and Guernsey have, unfortunately, their parallel in most of the country districts in the three divisions of the United Kingdom.

One of the Norwegian companies—the Drammens Uplands—affords a striking example of profitable rural telephony. The area for which it holds a concession from the Government extends over five counties and measures 143 miles from north to south, the most important places served being the villages called Kongsberg and Hönefros. At the end of 1894 the company possessed 24 switchrooms, 292 subscribers, 478 miles of poles, 1,553 miles of lines, including 671 miles of metallic circuits. Its annual subscription, which covers a line not exceeding two kilometres in length, and the right of free conversation over the whole of the five counties, is only £5. 11s. 1d. Its capital account stood at £9,815 ; its receipts from all sources for the year amounted to £2,332 ; the net profit was £752 and the dividend 6 per cent. This dividend has been paid regularly during the five years of the company's existence, and a deterioration and reserve fund built up besides. These are facts which should surely plead against the present era of telephonic stagnation.

The technical features of the continental systems are, as a rule, best where the tariffs are lowest and the extension of communication greatest. The conditions laid down by the author in his paper on "The Telephoning of Great Cities," read at the Cardiff meeting of the British Association in 1891, as being necessary to a well-ordered exchange, are fulfilled more nearly in Sweden than elsewhere, especially by the General Telephone Company, which operates in Stockholm and a radius of 43½ miles around. Metallic circuits are universal ; special attention is given to prompt switching, and Stockholm is divided into eight nearly equal divisions each containing a switchroom. The prompt and economical addition of new subscribers is thus rendered easy. The speed achieved in switching is that stated in the paper to be practicable and proper in a good exchange—viz., 10 seconds. The countries comprising Groups II. and III. are, with some exceptions, technically behind those of Group I. The reason lies on the surface. The conditions which prevail in Group I. bring about rapid extension ; rapid extension involves the solution of problems which do not present themselves while exchanges are in their infancy, and the solution of such problems evolve superior engineers.

THE DEVELOPMENT OF THE TELEPHONE SERVICE IN AGRICULTURAL DISTRICTS.*

BY MAJOR-GENERAL WEBBER, C.B, R.E., M.I.C.E.

On April 20, 1895, the *Times* published a letter on my subject which I had written to them as follows :

"The Telephone in Rural Districts.

"Sir,—May I occupy a few lines of your space in attempting to show that the telephone as well as the light railway may (in the words of the Queen's Speech) be 'found beneficial to the rural districts.' In many countries the telegraph (including the telephone), which is the handmaid of railways, has been their pioneer, often because the capital outlay required for its establishment is comparatively small. As the future fate of the telephone service of this country is at the present hanging in the balance, it seems an opportune moment to draw attention to the question from the point of view of the 'continued seriously depressed condition of agriculture.' The county is the unit of area with which I have studied the subject, and the district round each market town is the natural site of an exchange system, with inter-communication between market and county towns. Some of the advantages of a complete telephone service to the dwellers in the rural districts of a county through the establishment of a call-office in nearly every parish can be easily realised : to the farmers, the being able to converse with salesmen and customers at the market towns, saving journeys, and avoidable movement of stock and produce ; to the village tradespeople, the facility of promptly replenishing small stocks ; to the inhabitants, the power to converse with the shopkeepers in the market towns for their larger purchases, thus keeping trade within the locality ; to the dealers in perishable articles, such as milk and fruit, the value of the advantage is not easy to compute. The distribution of labour and material to meet demand would be better guided and expedited than existing means of communication admit of. Fire-engines and ambulance aid could be promptly summoned to places however remote ; and, lastly, the administration of the executive duties of the county council would be enormously helped. I have worked out a scheme for such a rural telephone service in one of the purely agricultural counties, which has nearly 400,000

* Paper read at the meeting of the British Association at Ipswich.

Digitized by Google

inhabitants and a gross rental of nearly two millions, and the figures present a very hopeful result. The material used would be what military telegraphers would call 'light permanent line,' and of the character largely used in Europe for the telephone. Such a county would require 29 exchanges, and call stations at 415 villages and hamlets. The length of pole line required to be erected would be a little over 1,000 miles, and the length of wire to be run a little over 4,000 miles. These figures are exclusive of the lines from private premises to the exchanges, which might in time be reasonably expected to number 700 or 800. The capital outlay would be about £49,000, and the annual cost, including interest, sinking fund, maintenance, renewal, working, and management, would be about £12,000 per annum. These figures are based on cost price, as if the work was undertaken by the county council. To cover this a charge of 2d. would be made for each conversation of five minutes within arranged areas, and this must amount to a daily average of takings at each call-office of 1s. 11d. The value of the service to the county administration and the net result of the revenue from the private lines would be profit. How far such a scheme would fit into the existing postal-telegraph system, or interfere with or help it, is more a question for the Parliamentary Committee, now sitting on the subject than for your pages. Without any delegation from them I venture to advocate the cause of the local authorities in the 120 counties in the United Kingdom.—I remain, Sir, your obedient servant,

"C. E. WEBBER."

On May 14, 1895, I was examined before the committee of the House of Commons on the subject, and gave some details of the proposals contained in that letter. It has occurred to me that as the suggestion if carried out throughout the United Kingdom, whether by the Post Office or by local authorities, would involve a very large expenditure, that, from the engineering point of view, this section is an arena not unsuited to its discussion. I have therefore entirely revised the figures in detail, and prepared the map of the county of Suffolk which is exhibited. Neither the National Telephone Company (the monopolists for 15 years of the telephone in this country) nor the Post Office would ever dream of adopting such a development of the service as that which I have suggested. I therefore do not expect to receive support from either of those bodies from the revenue and commercial point of view.

As a natural consequence of the meeting of the British Association this year being held at Ipswich, I have selected the county of Suffolk as the most suitable area for an example of the proposed work. The map of the whole county before you is on the 1in. scale; and it will be seen that every sub-post office is marked on it with a blue disc, and that each office which is also at present a telegraph office is marked, in addition, with a flag. The places at which under my proposals a telephone exchange office would be established are distinguished by a red circle outside the blue. At present the main telegraph lines throughout the county are, with one exception, placed on the railways—that exception being the road line from London to Lowestoft, which was erected on the main road which lies throughout its length contiguous to the main line of railway of the Great Eastern Railway Company. This line I had the honour to lay out and construct in 1870, being then divisional engineer of the postal telegraphs in this part of England. The other telegraph lines in the county are almost exclusively short branches from the railways to the post offices at the large and small market towns, numbering altogether 105.

The number of places at which under my proposals it is intended to establish telephone call offices in addition to those where telegraph offices exist is 246. This makes a total of 351 places in the county of Suffolk where telephone communication could be had by the public. The places, included in the above 351, at which exchanges with public connections would be established are: Lowestoft, Beccles, Bungay, Halesworth, Southwold, Saxmundham, Aldeburgh, Wickham Market, Framlingham, Woodbridge, Felixstowe, Eye, Debenham, Batesdale, Haughley, Stowmarket, Needham Market, Thetford, Brandon, Mildenhall, Bury St. Edmunds, Newmarket, Haverhill, Clare, Long Melford, Sudbury, Hadleigh, Nayland, Ipswich; 29 exchanges in all.

These exchange systems will require the construction of 524 miles of new line along roads not already occupied with lines by the Post Office, coloured green on the map. They will also require wayleave for wires on 253 miles of existing telegraph lines along roads already occupied by the Post Office, coloured blue on the map. In addition, it is proposed to obtain wayleaves on 37 miles of existing poles on the railways, coloured red on the map. Giving a total of 794 miles of lines to form the systems. For obvious reasons it is proposed to have only one wire with earth returns for each circuit; but it is also proposed, where interchange between exchanges is required, and in special cases to prevent the effects of induction, that such shall be effected by means of twin wires. On the map the lines alone are shown by a single line of the green, blue, and red, as the scale will not allow of the individual wires being distinguished.

It is not suggested here as a necessity that the existing Post Office poles should be used. A new pole line could be erected along the same road, but it is obvious that where there is space to carry additional wires it could be made mutually advantageous to use them. For this user the county telephone system would pay an annual wayleave at the rate of 10s. a mile of conductor, single or twin. The number of wires, including trunks, for which space will be required on a pole, whether it is an existing one, or one especially erected, varies from one to eight. The average will be five. This will require a total mileage of 3,970 new wire. In the construction a much lighter material can be used than that to which we are accustomed by Post Office use. The poles, which will be of a size to be procured largely in the district, may or may not be creosoted. Their cost will average in either case £12. 10s. a mile, and £20 a mile when erected complete with brackets, insulators, struts, and stays. In some out-of-the-way districts the Post Office allow themselves to limit the poles to 17 to 18 to the mile, but I should provide 22 to 25. The insulators would be small single shed, as used in France and Switzerland, having a bent shank to screw into the timber. They may be fixed within 9in. of one another, measuring vertically on the pole. The conductors would be of No. 18 bronze, and costing £5 per mile when "run." In case the Post Office should demur to the call-boxes being placed in sub-offices, there is little doubt that small shopkeepers would be found willing to provide the call office and take charge of it, with a payment of, say, 2s. 6d. a week and a percentage of the receipts after they have reached a minimum, say, of 2s. a day, added to which would be the advantage of attending the circuits of private subscribers. No skilled labour is required, and the necessary attention and attendance could be given by the youngest girls of a family. On the Continent of Europe, the village schools arrange that boys and girls shall have leave of absence in turn for such duties. When we come to our senses on the subject of withdrawing country children from rural occupations to sit all day in a school, the same thing would be done in Suffolk.

The cost of the system for Suffolk may be estimated as follows:

29 exchanges at an average of £151 (This provides for 50 per cent. spare connections.)	£4,375
351 call stations, at an average of £7 10s.	2,633
524 miles of new lines, at £20 per mile	10,480
3,970 miles of wire run on new and existing poles, at £5 per mile, with double conductors in the case of 950 miles	23,820
Add 1-10th for contingencies	4,130
Total capital cost of the system	£45,435

The receipts or takings of all kinds will have to provide for the following annual expenditure and allowances, so that if the system were established by the County Council there should be no charge on the rates:

Interest and sinking fund on £45,500 at 4½ per cent.		£1,933
Renewal fund—Of poles at 7 per cent.	£733	
Of wire and instruments, at 3 per cent.	238	
		971
Private wayleaves (estimated)		524
Wayleaves on existing poles, for each double or single conductor at 10s. a mile		675
Management		300
Maintenance—salaries and wages: one inspector	£200	
One assistant inspector	150	
Four linemen	280	
Small stores and sundries	250	
		880
351 call offices, rent, attendance, including small stores and sundries, average £9		3,159
29 exchanges—Salaries	£80	
Rent	12	
Small stores and sundries	10	
	£102	= 2,958
Add 5 per cent. for contingencies		573
Total annually		£11,973

Say £12,000 a year.

The greatest portion of the above payment for wayleave on existing poles would be a clear gain to the Post Office revenue. The cost of private wayleaves might be much less than the amount estimated, if the lines are the property of the County Council. The value of the service to the administration of the county I place at £350 per annum. It will thus be seen, after also deducting £900 for profit on private lines, the most that must be earned is £10,660 per annum. That individual occupiers of all ranks would be found ready and willing to pay for the convenience is highly probable, but its application would be limited, owing to the great facilities proposed to be afforded at the public call offices.

One of the chief inducements to the possession of a private line to one of these exchanges would be the facility given for communication with the postal telegraph system of telephone lines. Naturally a Post Office license for such a telephone

Digitized by Google

system in the county of Suffolk would include the obligation to connect up with all the postal telegraph offices in the county. In most cases it may therefore be held that the subscriber will wish for a service necessitating two wires. Estimating the average distance of a subscriber's house from the exchange at 2½ miles and that 1½ miles of this will be on special poles, and that each will require a twin-wire conductor, the outlay on each private subscriber's line would be on an average £71. With this outlay a profit of £3 out of an £8 annual subscription is not an over-estimate, the outgoings including a special extra payment at the exchange for services for each such private subscriber, which would be an increment to the wages of the call-office attendant. It is not too much to expect that three or four hundred private subscribers in one large county like Suffolk may be expected in time, whose subscriptions would yield a net revenue of £900 to £1,200 per annum.

The next aspect of the question from the County Council point of view is the value of the assistance given to the conduct of county business. I have consulted several chief constables, and they are all unanimous in testifying to the great help such means of communicating about the county would afford to their department both as regards efficiency and economy. The same remarks apply to the departments of sanitation works, health, and education. No small facilities would be given to all operations affecting the exercise of the suffrage at elections for all purposes. The various district and parish councils would be more in touch with one another and with the supreme county authority. To all this service I have attached the exceedingly low valuation of £350 per annum. As regards trade, it is not too much to say that saving of time is the essence of the acquisition of profits, and, that, if this can be achieved at a very small cost in proportion to the service rendered, an infinity of processes in the smaller industries and trades can be helped, on a scale which the telegraph and telephone—the most important means of saving time—have never yet attempted. Light railways—with which I have dealt in another paper read before this section—may or may not be financially possible to take the place of the present means of transport in agricultural districts: they are a substitute for something already in use; but such a system of telephony as I have described is an entirely new development of a means which may prove a first necessity of the daily business life of the small cultivator and village tradesman, as it must evidently be in that of the farmer.

I submit the following for consideration, as indicating the uses to which the telephone may be put in rural districts: The being able to converse with salesmen and others at the market towns would save journeys and premature movements of horses, beasts, and produce. The power of speaking with another farmer or bailiff at another farm, in another village, on questions of exchange of produce, labour, transpost; also as to meteorological conditions. The village tradesman would have increased facilities for meeting wants that otherwise require a journey of himself or of his customer. Purchases in the market town from the superior tradesman could be made by conversation, and perhaps the expenditure of money be kept within the locality, instead of sending to London or the large towns for small articles of consumption. All that appertains to the service of stallions and bulls would be more simply settled by conversation than by letter. Questions regulating the accumulation and transport of perishable food material, such as milk, would be assisted, and time and occasional confusion and loss would be saved. Farm labour, male and female, would have opportunities of information as to demand and supply, and market-town hirings would be diminished. Besides this, social gatherings amongst all classes, to the advantage of out-of-the-way districts, would be promoted, indirectly checking the migration of the rural population to the towns, and the operation of lending libraries would be assisted. Naturally, the question of the early arrival of medical aid and ambulance assistance, and in case of fires, occurs to anyone who considers the subject.

Now, as to the charge to be made for each use of a call office, the audience may be surprised to hear that I propose to put this at 2d. for three minutes to cover the use of one exchange, with a small addition, say, of 1d., if it is necessary to communicate through two or more exchanges within the county. The rates external to the county would be governed by those over the postal telephone trunk lines. It is only necessary for the gross takings at the 351 call offices to be on an average of 2s. per diem for 309 days in the year in order to cover the £10,660 outgoings already calculated above. I should be inclined to keep the system open for 16 hours out of 24, but that is a detail, and may vary according to local circumstances. Of course, by previous arrangement for official purposes it could be kept open continuously at a correspondingly increased cost for attendance. If the takings average 2s., I should propose appropriating a part of them to a fund to be used as premiums for good service of the employés. For the messenger service required to summon a correspondent and bring him to the call office a special charge per quarter of a mile would be made, and need not exceed one penny to be paid at the time by the person called. It is not to be expected that the Post Office could look on with perfect equanimity at the realisation of such a scheme as this, because they will at once apprehend a lessening of revenue at their 105 county of Suffolk telegraph offices. I have no information as to the number of forwarded and received messages at those offices, but it would be interesting if the Post Office will give these figures for the year since the adoption of the sixpenny rates, both as regards what might be called local and external traffic. I think it is highly probable that the quantity of local messages only would be affected, and that there would be a compensating increase of external telegraph messages. Besides, as the local telephone exchanges would be in communication with the telegraph system, there would doubtless arise a very considerable correspondence by telephone over the Post Office trunk wires, which would be a new and hitherto untapped source of revenue. There is also a compensation in the wayleave rental of £675 a year, payable to the Post Office, to which I have already referred. I would observe that Post Office objections, if any were made, on account of loss of revenue through a decrease of correspondence between, say, one county and another, or between the county towns and the Metropolis, should such arise, might lead to letting light in on a question which I believe has not been sufficiently considered—namely, whether the wide extension of telegraphic and postal facilities in the last 25 years may not be one of the indirect causes of what is called agricultural depression. For while these particular facilities have been increased, those for the economical conveyance of persons and goods have shown no corresponding advance. By this, what might be called the due balance of means for advancement of local trade has not been secured, and it may very possibly be shown that through such an apparently trifling absence of adjustment, the great diversion of trade for the supply of London from the country districts of England to the Continent has been assisted.

I do not think we need sympathise with the departmental objections of the Post Office to the loss of revenue on what might be called the "private wire branch." Ever since the transfer of the telegraphs to the Government the charges for such service have been practically prohibitive. Some idea of the exorbitance of these rates is given by the fact that, if such a system as I have described was established in Suffolk by the Post Office and rented to the County Council to work for the use of the inhabitants, the rent alone for the lines and stations, at the Post Office published rates, would be at least £18,658 a year for what in my estimate costs £5,388 a year, and each private subscriber would have to pay on an average about £20 a year. As regards what the National Telephone Company have done in Suffolk up till now I can obtain no information, although I have applied for the information to the company.

I hope that it will be realised that what I have described is entirely practical and feasible. I have not allowed in my estimates for a contractor's as well as an engineering profit, but the funds I have detailed for are amply sufficient. Also that if undertaken by the local governing bodies great benefit would arise without any charge on the ratepayers. It is hard to believe that the system would not become very popular in the use, and in the interim, say for the first three or four years, the Post Office might well forego any royalty, seeing that the late and present Governments have expressed such warm sympathy with the conditions of the greatest industry in the land. As I have suggested, it seems reasonable to believe that the facility afforded of being able to converse between county neighbourhoods, and between them and urban and suburban districts, will do much to check migration to the large thickly-populated centres. If you annihilate distance for purposes of conversation, may you not do away with many an excuse for accusing country districts of being "too dull to live in?"

Joint Discussion on General Webber and Mr. Bennett's Papers.

The Chairman (Prof. L. E Vernon-Harcourt), in proposing a vote of thanks to the authors, said that General Webber's proposals struck him as rather Utopian.

Prof. Silvanus Thompson said that, after listening to the papers just read, they could not but be impressed by the backwardness of the United Kingdom in the important matter of telephonic communication. The contrast that had been drawn between the Grand Duchy of Luxemburg and the county of Dorset was not flattering to our national pride, and Suffolk, judging from the figures cited by General Webber, did not appear to be much better off than Dorset. The time had come for the Government to make an earnest effort to give the telephone freer play. One select committee had met and proved abortive, and another was mooted, and this he hoped would meet soon and come to an early decision The Government had three courses open: (1) to take the whole telephone system into its own hands on terms that were fair to the subscribers and calculated to meet the requirements of the community, at the same time avoiding paying exorbitantly for the existing lines, into the cost of which "watered" capital and payments for expired patents entered largely; (2) to maintain the present monopoly; (3) to grant additional licenses and allow municipalities and others

Digitized by Google

possessed of spirit enough to find the necessary money, to share in the development of the country and give it the benefit of their enterprise unhampered by superfluous and "watered" capital. The continuance of the present state of things was impossible, and he called upon the Government to make a definite choice of the course to be pursued, and then to follow it with decision and a liberal interpretation of public requirements. Monopolies he did not like, but if a monopoly was necessary, he thought that it should be in the hands of the State, which was, in a certain degree, amenable to public opinion, and not in those of a private company.

Sir Frederick Bramwell said that he was old enough to recollect the controversy which raged around the proposal that the Government should acquire the telegraphs, and he remembered that one of the strongest arguments advanced in favour of that step was that, while companies were prone to serve only important towns and localities from which a paying traffic could be derived without much outlay or trouble the Government would provide telegraphic facilities in smaller towns where profits could hardly be easily acquired, since the benefit of the community as a whole would naturally be regarded more than immediate returns. That was the theory. The practical outcome, however, was that if the inhabitants of a small town or village wanted the telegraph the Post Office said: "We will put you in the telegraph on condition that you give us a seven years' guarantee that we shall suffer no loss So much is required to cover expenses. If the receipts fall short of this you must make the deficiency good." That rule had been enforced in a village in which he was interested. The guarantee had been given, and the Post Office had erected a wire, and put a telephone at the end of it in lieu of the usual telegraph instrument. The receipts did not cover the guarantee, and for the past two years he had been called upon for his share of the deficiency. That was how the Government treated the telegraphs; possibly they would act similarly in regard to the telephones if they got them—he could not say. But he must own that he thought General Webber placed too much emphasis on the importance of agricultural communication. There were, he thought, few agricultural matters that called for prompter treatment than the postal service afforded, and the fact that the guarantee required in the village he had referred to had to be made good, showed that the villagers did not much care for the telegraph when they had got it. Why, then, should they act differently with regard to the telephone?

Mr. Robertson said that, as one possessing a good knowledge of the shortcomings of the existing systems of communication in Suffolk, he could not endorse the conclusions of the last speaker. The scheme of a telephone system for Suffolk, which General Webber had prepared and put before them was, in his opinion, eminently calculated to facilitate intercourse throughout the county and to benefit its trade. The telephone was not on all fours with the telegraph. As he understood it, General Webber proposed to bring some dozens of small places which were not touched by the telegraph at all into connection by means of the telephone; he would therefore provide local communication, which the telegraph did not. Villagers did not often want to telegraph to strangers at great distances, hence the small use they were apt to make of the telegraph; but if they could communicate readily amongst themselves and immediate neighbours in the county a different state of things would arise, and it was certainly premature to foredoom to failure an experiment which had never been tried. At the same time some degree of education in the uses of the new facility would probably be required, and he was not prepared to say that the scheme would prove remunerative from the outset, although he believed it would be so later on.

Prof. A. C. Elliott said that he was struck by the facts regarding foreign telephonic progress set forth by Mr. Bennett, and would be glad to learn whether this gentleman was prepared with any scheme for remedying the existing unsatisfactory state of things in the United Kingdom.

General Webber, in replying to the chairman, said that at first he had been sorry to hear his proposals characterised as Utopian by the chairman, but on reflection, was quite content because no new proposal had ever been brought forward in this country that had not at first been stigmatised as Utopian. That applied to every important industry and invention that could be named, and he could not expect better treatment than had been accorded to railways and telegraphs. His scheme for Suffolk might be styled Utopian, but what were the facts? He proposed 26 telephone exchanges for Suffolk, and Mr. Bennett's map of Luxemburg showed that 59 exchanges already existed in that country, the area of which was less than that of Suffolk; and that each and all of these were connected by trunk lines. There could be nothing Utopian about his scheme therefore, for it was already excelled elsewhere. He was sorry Mr. Preece had taken no part in the discussion, and supposed he was deterred by his official position. Nevertheless, he should have liked to have heard Mr. Preece's opinion, as an engineer, of the figures he had put forward and which he had been told were, if anything, over than below the mark. If Sir Frederick Bramwell could become acquainted, as he wished he could, with the very numerous agricultural friends which he (General Webber) possessed in Norfolk and elsewhere, he would alter his opinion as to the country people not understanding or requiring the telephone. On the other hand, he had been the recipient of many communications which showed that the exact contrary was the case; they fully appreciated its conveniences, and regretted that the opportunities of taking advantage of them were withheld.

Mr. A. R. Bennett said that he would like to explain that his paper had not been written in concert with General Webber. The General had evolved his scheme for Suffolk, and he (Mr. Bennett) had independently prepared his own paper, which accidently, but none the less, he thought, appositely, showed that the General's ideas were not only not Utopian, but had actually been given effect to, not in one, but in many places abroad. As an Englishman, he could not regard with complacency English counties like Dorset represented by blank spaces on the telephonic map, while Luxemburg, Finland, Norway, and other countries were shown in an advanced state of development. He had heard the remarks about the want of understanding and enterprise said to characterise the British peasant and the British agriculturist, but he would not for one moment admit that the inhabitants of Suffolk or Dorset or Jersey were one whit less intelligent or less disposed to take advantage of modern improvements than Finns, Norwegians, Luxemburgers, or any other foreigners whatever. The differences in the results obtained were due entirely to the differences in the modes of administration and the opportunities afforded. The telephone in this country had been made a mystery of, and by means of exorbitant prices the impracticable regulations had been removed from the ken of those of moderate means. Abroad, matters had been differently managed, and foreigners were consequently in possession of aids to trade which were denied at home. During his long experience he had had many opportunities of judging of the utility of the telephone for general and agricultural purposes, and his earnest advocacy of a free extension and more liberal measures was the outcome of this experience That experience also taught him that General Webber's estimates for constructing the proposed lines in Suffolk were sufficient, and were even rather more than sufficient. He had no doubt that the work, under competent supervision, could be done, and done well, for the sum named. In reply to Prof. Elliott, he thought that the methods that had placed the Scandinavian countries at the head of well-telephoned countries were those which should be at least tried in this country. It was evident that the characteristics of management which had produced such good results were not reconcilable with any form of monopoly, and he would certainly recommend the Government to see what a freer trade in telephones would accomplish before deciding on either the first or the second alternatives suggested by Prof. Silvanus Thompson.

The **Chairman** said that the state of development attained in Luxemburg and other countries mentioned was certainly remarkable, and pointed to greater possibilities at home than he would have anticipated; but the telephone was not a branch of engineering which had come much within the scope of his experience, and he was perhaps hardly competent to judge. He could scarcely appreciate General Webber's point when he attributed depletion of agricultural districts partially to the action of the post and then proposed to cure it by means of the telephone. But all would agree that the development of telephonic communication in this country was greatly to be desired, and they must hope to see it speedily brought about.

THE MODERN APPLICATION OF ELECTRICITY TO TRACTION PURPOSES.*

BY PHILIP DAWSON.

(Continued from page 326.)

In 1890 there were 2,523 miles of electrically-operated track and 5,592 motor cars within the U.S.A. and Canada. In July, 1895, 10,752 miles of trolley wire had been erected furnishing current for 35,004 electric cars. Approximately, these figures mean an investment in equipment of £50,000,000 sterling.

European progress has been more slow. This is not unnatural, for there has been no such pressing necessity felt upon this side of the Atlantic under the more settled conditions which here prevail. In 1890 about 60 miles of electric lines were in operation. To-day there are approximately 500 miles of elevated conductors and 1,500 motor-equipped cars, while the lines under contract easily equal, if they do not considerably exceed, the sum total of all that has heretofore been completed. The results are set forth in accompanying tables, which, while undoubtedly incomplete, embody the latest information obtainable (see Table IV.).

By far the greater proportion of European electric tramway installations are to be found in Germany, but during the past year great activity has been shown in France as well. Comparatively little has yet been done in the British Isles, but there is every present appearance of extensive installations being shortly undertaken. Dublin, Bristol, and Coventry are already in hand, and will probably have cars running during the present month. The electric tramways of the Isle of Man, South Staffordshire, Leeds, and Guernsey are undoubted successes.

No other European country can, however, show such applications of electrical motive power to distinctively railway work as are to be found in the Liverpool Overhead Railway or the City and South London Underground.

On the question of tramways in general, the attitude taken in Great Britain is distinctly opposed to that of all other countries. It may be safely said that wherever else we turn we find the tramway regarded, if not as an unmixed blessing, certainly as an indispensable public convenience. British

* Paper read at the meeting of the British Association at Ipswich.

Digitized by Google

regulations are by far the most severe, and it is difficult to see why their stringency should not be relaxed to some extent. Our theory would seem to be that all other vehicles must necessarily take precedence of the tramcar. It would certainly seem, in this democratic age, that the vehicle which most greatly conduces to the comfort and convenience of the public at large should be accorded a better place.

With the gradual change from animal to mechanical means of traction, most, if not all, of the objectionable features of the tramway have been eliminated. Its social status has been distinctly raised in the public estimation, as its importance as a factor in municipal economy has won recognition. The great cable and electric systems of America have equal dignity with the steam railways of the country, represent enormous financial investment, and are much more closely connected with the daily life of the people.

If American and Continental experience has proved anything, electricity surpasses all other methods of motive power in its general fitness for tramway and light railway service. It admits of a constant service of comparatively light cars or trains at reasonable cost, of wide variations of speed, of elasticity sufficient to meet the demands of great temporary increase in passenger traffic, of re-equipment without extensive interference with the highway, existing cars, or any public service.

It is essentially clean, safe, and controllable, and no specially high class of employés are required in any department of a line. It has distinctly passed the experimental stage in every detail, and the apparatus has reached the point where interchangeability of parts and ease and simplicity of repairs can scarce be carried further. Every possible accessory is highly developed.

Curves, grades, switches, crossings, main and branch line service present no difficulties to-day, however greatly they may have impeded the pioneers in the development of electric traction.

All that has been said is especially applicable to the trolley wire system, which is the only one that has received any wide acceptance. The conduit has still to demonstrate its efficiency on a large scale, although Budapest and various Continental and American trial lines are now in operation. It may be considered certain that no sub-surface system will ever equal the elevated conductor, from the operator's point of view. Manifold difficulties in insulation, points and crossings, and connection between conductors and motors must be overcome. Moreover, it is more than doubtful whether the trolley wire and its supports are sufficiently objectionable to compensate for the great expense and manifold disadvantages attendant upon reconstruction of roadway and interference with existing sub-surface sewers, gas and water pipes and mains, telegraph, telephone, and lighting cables, etc. There is no reason to presume that an electric railway conduit should be cheaper or smaller than a cable railway conduit. Drainage requirements are the same, and the question of effective insulation resolves itself largely into one of sufficient space. At all events, America is the home of both cable and electric railways, and we note that the engineers having now in hand the installation of trial electric conduit lines, are rigorously following the most substantial form of cable construction. In the English climate it is well known how great the difficulty is of securing proper insulation, and it would seem certain that we could not afford to put in anything smaller or less costly than is apparently deemed to be necessary across the Atlantic.

At all events, it may be taken—to quote Prof. Silvanus Thompson—that of all overhead wires the trolley is the least unsightly, and has the best excuse for its existence.

The "third rail" system is applicable only to lines where the public has no access to the permanent way, or to toy lines employing currents of extremely low potential.

In fact, a paper dealing with modern electric traction, without speculative reference to future developments, must be solely confined to the trolley system, and we will therefore proceed to discuss its component parts.

Power Plant.—Upon the location and design of the generating station (with reference to the centre of current distribution) and the selection of the apparatus used therein, primarily depend the efficiency and economy of the whole system. The load is constantly varying, widely and unexpectedly, and the smaller the line, the greater the fluctuation, and the consequent reserve power required. An electric tramway operating five cars might easily need 35 station indicated horse-power per car, while a 50-car road should not require more than 15 i.h.p. per car in the power-house. For units under 500 h.p., high-speed rope-driven engines can advantageously be employed. Larger units require slow-speed direct-coupled engines of the Corliss type. Whatever the engine it must be built especially for the work in question, and able to stand overloading to the extent of nearly double its normal output. In fact, the strains to be met approximate those to which the engines of a rolling-mill are subjected. Extra heavy flywheels are always employed. Governors should be so constructed that under any variation of load the speed should remain constant within 2 per cent.

The dynamo must also withstand heavy overloading, and as one pole is earthed the best insulation must be employed. Very heavy magnetic inductions are allowed for to avoid sparking and the necessity of shifting brushes. From every point of view the over-compounded type of generator is the best. The design should be such that at no load the pressure between terminals should be 500 volts, increasing to 550 volts as the full load is thrown on.

When the ordinary practice is to employ compound-wound machines in parallel in the two-wire system, the three-wire system has been successfully adopted at Portland and St. Louis (U.S.A.), two generators being connected in series, one wire attached to the rails and the other two to alternate insulated sections of the trolley wire. The result has been to notably reduce the current in the rails, and consequently the section of feeders. Very considerable difficulty has, however, been found in maintaining a proper balance.

As it often happens that single feeder cables are called upon temporarily to carry exceedingly heavy currents, automatic circuit breakers must be placed in all circuits.

The motors employed must be light, strong, and simple in construction—completely encased—able to run continuously for hours at rated capacity without undue heating, and to exceed that capacity by 50 per cent. when required without injury. The starting torque must be great. The average horse-power exerted by a motor at the car wheel probably does not exceed 20 per cent. of the maximum power it is expected to exert in starting a car under various conditions.

To get the best efficiency out of such a motor, it is necessary to have its point of highest efficiency at that horse-power at which the greatest amount of work is to be done. To minimise the losses through hysteresis, eddy current, and friction, and at the same time to obtain the required torque, it becomes necessary to use the greatest number of armature-turns compatible with easy running and absence of heat and sparking. To ensure the latter it has been found necessary to use very heavy magnetic inductions, such as 100,000 C.G.S. lines of force per square inch in the yoke, 60,000 C.G.S. lines in the air-space, and 80,000 C.G.S. lines in the armature core.

It is universally considered that the drum armature, wound so that coils of different potential do not cross each other ("Eickemeyer") is most advantageous. All coils are made separately on forms and then bound down into wedge-shaped grooves cut in the face of the armature core. The use of paper insulation between the armature discs has been discarded, and the formation of Foucault currents is prevented by heating the discs, thus covering their surfaces with a black oxide which suffices as insulation.

The standard motor used on European and American electric lines weighs approximately 1,500lb., and is rated at 25 h.p.; that is to say, it will exert a horizontal effort of 800lb. through a 33in. wheel continuously.

Every variety of gearing has been tried in turn, in order to secure the most efficient method of reducing the speed of the armature and transmitting its action to the car axles. Double and single reduction spur gear, bevel gear, belts, single and double chain gear, and worm gear, have all been submitted to most extensive tests. Practically, all motors are now standardised on the single reduction spur and pinion, from which gearing an efficiency of approximately 95 per cent. is now obtained. The pinions are of steel, and the spur wheels of cast iron. Epicycloidal teeth are almost universally employed. The gears are always run in oil, and the life of the pinions and spur wheels, which in the old double-reduction type of motor was respectively 9,000 and 29,000 miles, has been more than doubled.

Practically, the only method of control now employed in traction work is the series-parallel system. This consists in the use of two or more motors per car, which by means of a special device are thrown into different combinations. These are shown in the diagram, and a typical controller is before you. The introduction of the series-parallel controller has resulted in a very great saving of power at starting, while four different speeds are attained without the waste of current in the resistances previously employed, and with a high efficiency in the motors. Reversal is effected by a separate switch, and interlocking gear prevents the motors being reversed until the current is turned off.

We have before us a model motor truck, showing the standard construction now utilised by most large American roads, and which is also employed by all the English tramways now under electrical construction. The model is so made as to show three styles of truck employed for supporting cars of different lengths, and it is fully equipped with two "G.E. 800" motors, and their gearing. It may be said that the introduction of electric traction has revolutionised running gear. The great addition to weight made by the motors and gearing has rendered it necessary that efficient methods be used for cushioning and suspending the motors upon their axles, while maintaining a rigid connection between motor and axle. Consequently the truck is to-day made so that it relies not at all upon the car construction for strength or support of the mechanism. The use of a reliable and efficient truck is quite as important as the employment of well-constructed motors. You will see that the design of the

model truck is practically that of a continuous truss such as would be used in cantilever bridge work. Every care is taken to evenly support the car body for its whole length, and to use such springs at the different points as will most readily accommodate themselves to both heavy and light loads. It has been found that the four-wheeled truck can be satisfactorily used for the support of car bodies up to 22ft. in length. For longer bodies bogie and radial trucks are employed. Many different type of bogies have been employed in order to get the maximum traction weight upon the driven axles; but as yet no one can say positively which of the several variations is the best. The six-wheel radial truck has been largely introduced with the desire of doing away with the waste of power due to skidding and grinding of the wheels on curves of small radius. It is composed of three independent two-wheel trucks pivoted together, the two end trucks carrying the greater part of the load and the motors. It cannot yet be said that this truck is wholly satisfactory, as it has a tendency to derailment. It is indispensable that mechanically-propelled cars in populous cities should be provided with thoroughly reliable safety apparatus, and you will note how very substantially the brakes upon the model truck are made. Several different systems of supplementary braking apparatus are in use, and on all roads operating heavy grades it is customary to employ air, electric, or additional track brakes to supplement the ordinary hand brakes. Safety fenders of many different types are also used to prevent the possibility of any person getting under the wheels, should he fall in front of a moving car. Sand-boxes, actuated by levers on the driver's platform, are alway provided.

The British tramcar, having seats on the roof, requires a somewhat different style of trolley from that usually employed on American and continental lines. Both types are before you, and it is scarcely necessary to further explain them. You will see that swivelling arrangements are provided whereby the trolley will easily and certainly follow the trolley wire from a point directly above the car roof to a point of 8ft. to 10ft. off to one side of the track. This adaptability of the trolley to a considerable variation of the wire from a direct line greatly simplifies construction, and enables the wire (as at Bristol and South Staffordshire) to be hung from short arms along one side of the track. In a few cases constructors have preferred to use scraping contacts, running along the underside of the wire rather than the wheel, but the great mass of opinion is strongly in favour of the use of the wheel contact.

Such adverse criticism as has been made upon the use of elevated wires for electric tramway service has largely arisen from carelessness in erection, and, in the earlier days, from the fact that the various accessories were still in an experimental stage, and unsightly apparatus was made up on the spur of the moment to meet exigencies as they arose. The first electric lines, both European and American, were great sinners in this respect, and the clumsy cobwebs of wires which they erected were undoubtedly most objectionable. With the enormous increase in traction business, it became worth while, from a business standpoint, for many expert mechanics to devote themselves to the elaboration of these details, and to the perfection of the apparatus required in their manufacture. Special poles, insulators, suspension devices, and all the many appliances required for crossings, branches, terminals, etc., have consequently been developed, and have greatly added not only to the efficiency of equipment, but to ease in erection and workmanlike appearance. A set of approved apparatus, such as is used in the construction of various British lines, is before you, and you will note that they are compact, strong, and not likely at a height of 21ft. in the air to be unduly conspicuous. In many Continental cities, the municipal authorities have prescribed that in all cases, where possible, the span wire supporting the trolley line should be attached directly to the house fronts by means of rosettes of ornamental design. Injurious effects to the buildings from vibration is avoided by the insertion of springs or indiarubber cushions. When this method is used all objectionable features are minimised to the greatest possible extent.

The span-wire system of construction, by which the trolley wire is held directly over the tracks is undoubtedly the most efficient, especially where high rates of speed are to be run through broad streets. Where the tramway track is along a single side of the highway, suspension from single bracket arm poles possesses the same advantages.

Much has been done on the Continent and in England in developing handsomely ornamented poles, which do not detract from the appearance of the street, and in many places electric arc and incandescent lamps are supported upon the same poles as carry the tramway wires. Several designs now in use are illustrated in the drawings before you. The employment of underground feeders adds much to the sightliness of the installation.

For a separation of a line into sections so that an accident upon one portion may not interfere with the whole line for protection against lightning, etc., ingenious apparatus has been developed, samples of which are on the table. In a few places double conductors are employed in order to avoid the necessity of using the rails for the return circuit, and the consequent bonding of joints required. These are, however, isolated instances, and the only large system worked in this manner is that of Cincinnati. It will easily be appreciated that such advantage as may be secured by the use of a double overhead conductor, is more than compensated for by the resultant increase in the number of wires suspended over the street.

To ensure an easy path for the return current is of great importance, and on the earlier roads, which largely trusted to the earth as a return, very serious difficulties were soon encountered. Heavy currents of electricity circulating through the metallic pipes and conduits along the line of the route caused their rapid corrosion. At first, enormous falls of potential were allowed, but nowadays it is rare that the fall of voltage on any line is allowed to exceed 20 per cent. British practice is, of course, governed by the rules of the Board of Trade, which specifies that the fall must not exceed seven volts.

It has now been definitely ascertained that heavy copper joints between the ends of the rails should always be employed and the rails relied upon for the return to the extent of their current-carrying capacity. When that is exceeded, insulated return-circuit feeders should be run back to the power-house. Bare copper supplementary wires laid the length of the track are utterly useless. The latest and most approved form of bond is the "Chicago" rail bond, which during the past year has come into very extensive use in Europe as well as in America. It consists of a copper rod having tubular terminals, which are inserted into poles through the web of the rail. The terminals are then expanded and wedged into solid contact with the metal of the rail by driving into each terminal a drift pin about 1-16in. larger than the thimble. This makes as nearly as possible perfect contact between the two metallic surfaces, excluding air and moisture, and preventing corrosion or electrolytic action in the connection. It must be borne in mind that the only contact which can be at all relied upon is that between the bond and the interior surface of the hole in the rail, and that the surface of copper in contact with that surface should be at least six times the section area of the bond.

Electric welding may demonstrate its success as a means for ensuring the return circuit, but it cannot be said as yet whether or no the results have been such as to warrant its extensive introduction. It must stand the test of some years' trial. Over 100 miles of track have been welded at joints in the United United States, and the work is still going on. It is too early yet to form an opinion as to its relative value compared with the system of heavy bonding which has now secured the widest approval. Specimens of bonds are exhibited.

As electric traction is applied on a more and more extensive scale, and great numbers of cars are operated by individual roads, the question of how to distribute current most economically attains great proportions. We have already referred to the three-wire system as having a considerable value. Three-phase distribution is also being tried upon an extensive scale in many places. The Dublin Southern Tramways, on the 8½-mile line which is now being constructed by the British Thomson-Houston Company, will employ a combination of continuous current and of three-phase alternating current transmitted at a pressure of 3,000 volts to two sub-stations respectively 3½ and 8 miles away from the generating station. Each sub-station contains two 60-kilowatt rotary transformers. At Sacramento, Cal., a water power 23 miles away from the line supplies 4,000 h.p. for the needs of that city, current being transmitted at a pressure of 11,000 volts. At Portland, Ore., current at 6,000 volts is transmitted from a water power 20 miles distant from the line. At Lowell, Mass., current generated by steam is transmitted to sub-stations respectively seven and 15 miles from the power-house at a pressure of 5,000 volts. In Switzerland we find several interesting applications of water power carried from a long distance at convenient voltages and transformed for railway and traction use to the ordinary potential of 500 or 600 volts. At Lugano, Messrs. Brown, Boveri, and Co. are undertaking an interesting installation, in which the cars are furnished with three-phase motors. A double trolley wire is used, and the rails act as the third conductor.

All this work is in the direct line which will some day lead to an extensive competition with steam as the motive power for railway services. Throughout America we find extensive application of electric traction to mining tramways, for the electric motor readily adapts itself to the contracted space of galleries and drifts, to the handling of freights in cities, goods yard, and factories. Messrs. Ganz and Co., of Budapest, have done most interesting and valuable work in this particular line.

It is unnecessary to refer to the equipment of the City and South London Railway and the Liverpool Overhead. These have been already thoroughly discussed and described before the learned societies, and the elevated railway at the Chicago Exhibition has also been referred to *in extenso* in the technical Press.

The Metropolitan Elevated Railway of Chicago will shortly be in full operation, running trains of four cars, of which one will be equipped with motors. The weight of the complete

Digitized by Google

motor car is nearly 30 tons, and the train complete will weigh approximately 100 tons. The speed, including stops, will be 13 miles an hour with the present equipment, but it is proposed to shortly operate six car trains at a speed of 15 miles an hour. The Baltimore and Ohio Railway have already in operation the first of a number of 96-ton electrical locomotives with which they propose to operate the 2½ miles of tunnels through which their lines run at Baltimore.

The dimensions of these locomotives are as follows:

Number of trucks (per locomotive)	2
,, motors ,, ,,	4
Weight on driving-wheels	192,000lb.
Number of driving-wheels	8
Draw-bar pull	42,000lb.
Starting draw-bar pull	60,000lb.
Gauge	4ft. 8½in.
Diameter of drivers	62in.
Length over all	35ft.
Height to top of cab	14ft. 3in.
Wheel base of each truck	6ft. by 10in.
Extreme width	9ft. by 6½in.
Diameter of sleeve bearings	13in.

Each motor is rated at 360 h.p., and takes a normal current of 900 amperes. An average speed of 15 miles an hour is obtained. The trains handled by these motors weigh approximately 1,200 tons.

Several of the greatest trunk-line railways in the United States have commenced the equipment of short branch lines with electrical plant. The Pennsylvania Railroad Company has 8½ miles equipped with trolley wire, over which their standard cars will be drawn by electric locomotives at a speed of 45 miles an hour. The New York, Newhaven, and Hartford Railroad Company has had some seven miles of electrically-equipped track in operation for some months, with 30-ton 42ft. cars, under the ordinary conditions of steam railway service. Other lines are preparing to follow their example. It is undoubtedly the case that the results obtained in America have conclusively proved that electricity is cheaper than steam wherever comparatively short lines with frequent stops are to be worked, and we are yet far from knowing the limit to which the comparative economy of electricity extends.

There would seem to be no reason why the same results which have been attained in America should not be reached in Great Britain. Certainly European progress seems to indicate that there is little or no difference between the conditions and requirements which must be met on either side of the Atlantic. We hear on all sides the demand for additional light railways, and to postpone their construction is to heavily handicap a great portion of our population in the competition which to-day exists with foreign producers. The tramway as it now is known in this country is behind the times, and our facilities for rapid transit most inadequate. There is much which we can safely take from the experience of other countries in its development and extension.

In the face of the numerous and successful Continental installations, it is impossible to reasonably maintain that the electric system fails to meet the requirements of city and suburban transit to an extent unparalleled by any other means of mechanical traction. The conditions of modern metropolitan life imperatively demand that our ever-increasing population be afforded vastly improved means of intramural circulation. Our over-crowded centres can no longer accommodate the great army of workers and their families, and access to outlying suburban districts should be facilitated by every possible means. For hygienic reasons alone, it is indispensable that the accessible residential zone surrounding our greater cities should be extended to the utmost limit.

The steam railway cannot efficiently or economically fill this demand, and animal traction is hopelessly inadequate. The trolley system does fill it absolutely, and has well-nigh every advantage that can be asked from an ideal system of traction. The overhead wire is its single objectionable feature, and it would seem not unreasonable to say that so comparatively small a drawback is of but little moment compared with many manifest advantages.

ON THE MAGNETIC FIELD DUE TO A CURRENT FLOWING IN A SOLENOID.*

BY W. H. EVERETT, B.A.

The only investigation hitherto published is that for a solenoid of circular section. The investigation, in which the idea of magnetic shells is used, is of a somewhat intricate character, although treated with Prof. Minchin's usual power, and the results are uninviting for practical application. In this paper the subject is approached by a simpler method—namely, by considering the force due to an element of current—and general expressions are obtained which can readily be worked out approximately to numerical values for a solenoid of any form and size. As a particular case, the results give the force components due to any plane circuit at any point in its field. Special application is made to the rectangular (or polygonal) solenoids, as commonly used for field-magnet coils in dynamos, the expressions being in this case integrable, and some numerical results are given. The paper also includes a remarkably simple expression for the force at any interior point due to a circular current.

* Abstract of paper read at the meeting of the British Association at Ipswich.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Tongres.—The Municipal Authorities of Tongres (Belgium) invite tenders by October 12, 1895, for the concession for the installation and working of the electric light in the town.

Paris.—Tenders are invited for the supply of electric cables, in two lots, for the Administration des Postes et des Télégraphes. Particulars are obtainable of the Administration, 103, Rue de Grenelle, Paris, where tenders are to be sent by October 10.

Alexandria.—The Municipal Authorities of Alexandria, Egypt, invite applications by October 1, 1895, for the concession of the tramway lines from St. Catherine Place, through the outer boule-yards, to the projected abattoirs at Mex, with a branch line. Security £E1,000.

Bedford.—The Electric Lighting Committee invite tenders for the supply and delivery of 200 cast-iron lamp columns, carriers, and globes, in accordance with plans and specifications, a copy of which can be obtained at the office of Mr. T. S Porter, clerk, Town Hall, Bedford, on payment of a fee of 5s. Tenders, marked "Electricity," must be delivered to the clerk by October 8.

Goole.—The Urban District Council desire tenders for fixing telephonic communication between Goole and Rawcliffe Bridge, a distance of about three miles, according to specification. Tenders must be sent to Mr. Geo England, clerk, marked "Tender for Telephone," by 30th inst. Further particulars and copy of specification can be obtained on application to the Manager, Gasworks, Goole.

Braila.—The Municipal Authorities of Braila, Roumania, invite tenders by October 2 for the construction and working of a system of electric tramways in the city. Provisional security, 10,000f. This contract was originally fixed for July 29. Tenders are further invited by the Municipal Authorities of Braila for the lighting of the city by electricity or by electricity and gas Provisional security 10,000f.

Chepping Wycombe (Bucks.).—The Urban Sanitary Authority for this borough are prepared to receive tenders from public companies for working the electric order obtained by them within the borough for a term of years and upon approved conditions. Tenders are to be delivered by noon on October 14 next, at the office of the town clerk, High Wycombe, where a copy of the electric order may be seen and further particulars obtained. The Authority do not bind themselves to accept any tender.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

Croydon.—The Council are prepared to receive tenders for wiring and for supplying and fixing electrical fittings at the New Town Hall, Courts, and Free Library. Copies of the specification may be obtained upon application to the architect, Mr. Charles Henman, A.R.I.B A., 64, Cannon street, London, accompanied by a deposit of £2. 2s., which will be returned on receipt of a bona fide tender. Plans of the lighting system may be seen at the architect's office, as above, and at the New Town Hall, Croydon. Tenders to be sent to Mr. C. M. Elborough, town clerk, by October 8.

Blackburn.—The Corporation of Blackburn invite tenders for the following: Contract No. 1.—High-tension concentric cables, low-tension triple concentric cables, cast-iron pipes, junction-boxes, drawing in boxes, service-boxes, etc. Specification, conditions of contract, and forms of tender may be obtained at the offices of Mr. E. M. Lacey, 10, Delahay-street, Westminster, on and after September 23, on payment of £1. 1s., which will be returned on receipt of a bona fide tender. Tenders, sealed and endorsed "Electricity Extensions," must be delivered at the Town Hall, Blackburn, on or before October 5.

Dundalk.—The Dundalk Town Commissioners invite tenders for erection of an electric lighting installation for the purpose of lighting the town by electricity on or about July 1, 1896, reserving to themselves the right of taking over the plant at the end of a

Digitized by Google

term of years—this term to be stated in the tenders. The successful contractor to have the right of supplying private consumers, while the Commissioners will pay a fixed sum yearly for the town lighting—this sum to be stated in the tender also. The Commissioners have obtained a license from the Board of Trade for supplying electric lighting. Tenders will be received by Mr. Edward Farrar, town clerk, Town Hall, Dundalk, up to October 7.

London, W.—The Great Western Railway Company desire tenders, among other stores, for the supply of telegraph instruments, telegraph apparatus, copper wire, G.P. wire, etc., telegraph ironwork and tools, telegraph drysalteries, carbons for electric light, iron wire, acids, alkalies, zinc, telegraph poles, from November 1, 1895, to October 31, 1896. Samples and patterns may be seen on and after 23rd inst. at the office of the stores superintendent, Paddington Station. Specifications, with forms of tender, may be obtained at the office of the stores superintendent at Swindon or Paddington Stations. Tenders, addressed to Mr. G. K. Mills, secretary, Paddington Station, London, and marked outside "Tender for Stores," will be received on or before October 7.

Eccles.—The Corporation invite tenders for the supply and erection complete of the following apparatus and plant: Lancashire boilers; alternating-current dynamos and engines; cables, street boxes, etc.; transformers. Tenders may be sent in for any section or for the whole of the sections, but not for part of a section only. Plans of the district can be seen and copy of the general conditions, specification, and form of tender can be obtained on deposit of £5. 5s., which will be returned on receipt of a bona fide tender, at the town clerk's offices, Eccles, or at the offices of the consulting engineer, Mr. S. V. Clirehugh, Temple-chambers, Brazenose-street, Manchester. Sealed tenders, which must be on the prescribed form, endorsed "Tender for Electric Lighting," to be delivered to Mr. Geo. Wm. Bailey, town clerk, Town Hall, Eccles, by 12 noon on 30th inst.

Belfast.—Tenders are invited for the supply and erection of two direct-coupled steam-engines and dynamos, battery of accumulators, main switchboard, and installation of about 232 incandescent lamps, complete, for the lighting of Belfast Lunatic Asylum, for the Commissioners for the Control of Lunatic Asylums. Tenders should be sent in a sealed envelope, endorsed outside "Tender for Works for Lighting Purdysburn Asylum," and addressed to the secretary, Board of Control, Custom House, Dublin, and accompanied by a separate sealed envelope, similarly addressed and endorsed, containing the detailed estimate. Forms of tender will be issued on application to the office of the Board of Control of Lunatic Asylums, Custom House, Dublin, on deposit of £1, which will be returned to all persons who have sent in bona fide tenders. Plans and specification can be seen at the office of Mr. O. A. H. M'Cowen, Chapel-lane, Belfast. Tenders by 10 a.m. on 28th inst.

Harrogate.—The Corporation of Harrogate invite tenders for wiring the new Montpellier Baths for electric lighting. Specifications and full particulars may be obtained of Messrs. Baggallay and Bristowe, architects, 66, Conduit-street, London, W., on payment of £1. 1s., returnable on receipt of bona fide tender. Sealed tenders, endorsed "Tender for Wiring New Baths," are to be sent to the town clerk, Municipal Offices, Harrogate, by September 30. The Electric Lighting Committee desire tenders for the supply and erection of the following plant: (Section A) Lancashire boilers, economiser, feed pumps, and accessories; (B) steam alternators, condensers, fittings, etc., steam, exhaust, feed, and sundry pipes, valves, etc.; (C) switchboard and instruments; (F) transformers and accessories; (G) meters; (H) overhead travelling cranes. Tenderers are at liberty to tender for any section or sections, or for the whole of the sections, but not for a portion of a section. Specifications may be obtained on application to the borough surveyor, Municipal Offices, Harrogate, on payment of £2. 2s., which sum will be returned on receipt of a bona fide tender. Tenders, sealed and endorsed "Tender for Electric Lighting," must be addressed to the town clerk, Municipal Offices, Harrogate, and delivered by September 30.

RESULTS OF TENDERS.

Huddersfield.—The tender of Mr. T. W. Broadbent, Victoria-lane, has been accepted for the lighting by electricity of the boot and shoe and confectionery departments, reading-room, library, etc., in John-street and Albion-street, Huddersfield, for the Huddersfield Industrial Society, Limited. Mr. J. Berry, 9, Queen-street, Huddersfield, was the architect.

Tunbridge Wells.—The following is a list of the tenders received for lighting the Great Hall, Tunbridge Wells:

E. Powell (accepted)	£86	18	0
Electric and General*	80	15	3
Laing, Wharton, and Down	90	15	3
Gilbert and Co.*	107	2	6
Ashby Wood	123	16	9
Hollingum and Saword	131	11	0
Drake and Gorham	168	19	0
S. E. Haward*	176	3	6
J. S. Cunnington and Co.	178	17	3
Tewson and Streatfield	199	7	6
Newton and Co.	198	11	5

The tenders marked thus (*) did not include the price of 120 lamps. The specification for the work was prepared by the consulting engineer to the Great Hall Company, Mr. R. W. Weekes, A.M.I.C.E.

Oldham.—The following were the tenders for wiring the Central Baths, Oldham:

Baxendale and Co., Manchester (accepted)	£32	7	0
Bennett and Druce, Preston	34	0	0
Crossley, Oldham	34	10	0
Day, Oldham	35	0	0
Lomax, Kendal, and Co., Manchester	37	13	6
Waring and Sons, Manchester	42	0	0
Charlesworth and Co., Oldham	43	7	6
Fletcher, Hirst, and Co., Burnley	45	7	6
Paterson and Cooper, London	47	0	0
Corlett Electrical Engineering Company, Wigan	47	10	0
Sansome and Co., Blackpool	53	0	0

West Cowes.—Eleven schemes have been submitted to the District Council for electricity works. The following is a list of the tenders received:

Low-tension, with accumulators.

Electric Construction Company	£5,155
Sharp and Kent	5,333
Bennett and Druce	6,150
Crompton and Co.	6,215
Johnson and Phillips	6,650
John Fowler and Co.	6,970
Greenwood and Batley	7,600
Siemens Bros. and Co.	8,100
India Rubber Company (informal)	—

High tension alternate-current, with transformers.

Brush Company	5,990
John Fowler and Co.	8,350

Mr. Nelson F. Dennis, A.M.I.C.E., the borough engineer, recommends for further consideration the offers of the Electric Construction Company, Sharp and Kent, Crompton and Co.

BUSINESS NOTES.

Julius Harvey and Co., engineers, machinery merchants, and contractors, have opened offices at Mansion House-chambers, 11, Queen Victoria-street, E.C.

Cardiff.—The Corporation have resolved to light the market by arc instead of incandescent lamps. The initial cost will be about £50 more, but a saving will be effected in the lighting of 3s. per hour.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 22nd inst. amounted to £1,239, as compared with £955 in the corresponding week of last year, being an increase of £284.

Stockport.—The Heaton Norris Urban Council have appointed a committee to collect information as to the cost of a system of electric lighting. The committee are empowered to take steps to obtain a provisional order if desirable.

Electrical Trade Organisation.—The electrical supply dealers and contractors of Buffalo, N.Y., have formed an association for mutual benefit and protection, and the placing of the electrical business in that city on a better footing.

Battery and Motor Company, Limited.—Mr. H. T. Barnett has resigned his position as joint managing director in the Battery and Motor Company, Limited, Bower-road, Victoria Park, N.E., and will now act as consulting electrician.

Shoreditch.—Nine tenders were opened at the meeting of the Shoreditch Vestry for insulated electric mains and conductor and drawing-in boxes. The tenders were referred to the Electric Lighting Committee, with instructions to report upon them to the Vestry.

Dover.—A new school of science, art, and technology, which has been erected by the Dover Corporation at a cost of £10,000, adjoins the Municipal Buildings, and is a notable addition to the architecture of the town. The school is lighted throughout with electricity.

Round's Accumulator Company, Limited.—This Company has been registered, with a capital of £10,000 in £1 shares. Object: to enter into an agreement with B. Round and others, and to carry on the business of electricians and electrical engineers, etc., in all or any of its branches.

Aluminium Cycle Fittings Company, Limited.—This Company has been registered, with a capital of £5,000 in £1 shares. Object: to carry on business as manufacturers of and dealers in cycle fittings, and as cycle manufacturers generally. Registered office: 164, Clerkenwell-road, E.C.

Tunbridge Wells.—Mr. Phipps Carey has held a Local Government Board enquiry with reference to the proposal of the Corporation to borrow £12,000 for an extension of the electric light works. Mr. Preece, the consulting electrical engineer, gave evidence, and there was no opposition.

City and South London Railway.—The returns for the week ended September 22 were £831, compared with £835 for the corresponding period of 1894, being a decrease of £4. The total receipts for the half-year 1895 are £10,148, compared with £10,238 for the corresponding period of 1894, being a decrease of £90.

Digitized by Google

Edinburgh.—The Town Council have agreed to extend the high-tension electric light system to East London-street by way of Broughton-street at a probable cost of £550. It has been remitted to a committee to consider and report as to the advisability of introducing the electric light in Grassmarket and West Bow.

Southport.—Less than a year ago the Southport Corporation began to furnish private customers with electricity, and to-day (Friday) additional works will be opened with a view to meeting the requirements of a constantly increasing number of customers, and also with a view to lighting the main thoroughfares by means of electricity.

Newquay (Cornwall).—At a statutory meeting of the shareholders in the Newquay Baths and Sanitary Steam Laundry Company, the chairman, Mr. Williams, said that the proposal was to light the buildings by means of the electric light, driven by their own machinery. This, he remarked, was by far the cheapest plan of illumination.

Wimbledon.—The Chairman of the District Council has written to the Local Government Board asking what powers the Council had in the matter of electric lighting, and has not yet received a reply. The London and South-Western Bank, Wimbledon, wrote that when the electric light was installed in the town they would be glad to have their offices lighted with it.

Crystal Electric Lamp Company, Limited.—This Company has been registered, with a capital of £15 000 in £5 shares. Object: to enter into an agreement with J. W. Rogers, and to carry on the business of an electric light company in all its branches. The directors are J. W. Rogers, H J. Gibbs, and F. Naylor. Registered office: St. Stephen's-chambers, Telegraph-street, E C.

Axbridge.—The Highway Board have received a letter from the Telegraphic Extension Office stating that the authorities were about to establish telegraphic communication from Weston-super-Mare to Brean Down Fort, and asking permission to erect the necessary poles on the highway between Oldmixon Bridge and Uphill. Consent was given subject to approval by the surveyor of the position of the poles.

North Staffordshire Tramways.—It is stated that a deputation of about 20 gentlemen, including the mayors of Stoke on-Trent and Longton and representatives of the Hanley and Burslem Town Councils and of other local authorities in the Potteries, have visited Havre to inspect the system of electric traction there, and that preparations are being made to introduce the system over the North Staffordshire tramways which serve the Potteries.

Glasgow.—At a specially-convened meeting of the Home Affairs Committee of the Glasgow Chamber of Commerce, the question of the alleged insufficient telegraphic communication between Glasgow and London was brought up by Mr. Charles Seligmann, and, after discussion, it was unanimously agreed to make strong representation to the Postmaster-General to provide adequate and increased facilities. A memorial to this effect will be at once presented.

New Firm.—Mr. R. F. Venner and Mr. A. Sillar, M.I.E.E., have entered into partnership as representatives of engineering and electrical firms, and will in future act as sole agents for Hookham's electricity meters for the United Kingdom (Birmingham and district excepted) and London agents and sole country agents for the Nalder and Harrison Construction Syndicate. Their London office and showroom is at 10, Delahay-street, Westminster, S.W.

Dublin.—A deputation from the Dublin United Tramways Company has sailed for New York by the "Teutonic" for the purpose of inspecting the newest methods of electric traction in the United States. The deputation consists of Dr. Carte, J.P., chairman of the company; Mr. John R. Wigham, J.P., president, Dublin Chamber of Commerce; Mr. Wm. M. Murphy, J.P., and ex-M.P.; and Mr. Wm. Anderson, J.P., secretary and manager of the company.

City of London Electric Lighting Company, Limited.—Mr. J. Cecil Bull, manager and secretary, writes: "It having been found that the scale set forth in the circular dated January 31, 1895, may be in contravention of Clauses 19 and 20 of 45 and 46 Vic. (cap. 56), it has been cancelled, and the allowances (except the reduction in meter rentals) will not become operative." Mr. Joseph Bevan Braithwaite, jun., has resigned his seat on the board of this company.

Carlisle.—Mr. Dixon said at the last Town Council meeting that in the minutes it was stated that the town clerk had presented a report on an electric lighting provisional order. Were they not going to hear anything about the report? Mr. Forster said that they had got a provisional order, and £430 had been paid for it out of revenue. Mr. Dixon: Don't you intend to go in for it? Mr. Forster: Ultimately. Mr. Creighton said that the matter was only brought up to date. The committee had not yet considered it.

Eastern Telegraph Company.—The directors announce the payment on October 15 next of interest of 3s. per share, less income tax, being at the rate of 6 per cent. per annum on the preference shares of the Company for the quarter ending September 30, and the usual interim dividend of 2s. 6d. per share on the ordinary shares, free of income tax, in respect of profits for the quarter ended June 30. The register of transfers will be closed from October 8 to October 15, both days inclusive.

Denbigh.—The Town Council have received an offer from the Edison-Swan Electric Light Company to lease an electric central station and plant for the town and supply light at a rate equivalent to about 4s. per thousand feet of gas if the town would erect the station, which would cost £6,000, on a 30 years' purchase, at the termination of which time the whole system would become the property of the town. The Edison-Swan Company would provide all the plant, engines, etc. The matter has been left to the Lighting Committee to consider.

Enfield.—Mr. Theodore Ellis, of Belcaro, Bycullah-park, Enfield, has written a letter asking for the support of the Urban District Council in the endeavour of an association which is being formed to obtain a provisional order to light the town by electricity. He included in his communication elaborate arguments in favour of electricity. It was decided to send the letter to the General Purposes Committee, and that Mr. Ellis be asked for further details, the Chairman remarking that if they decided to have a refuse destructor they would have to consider whether they ought not to keep the electric lighting in their own hands.

Cutting and Polishing Powder.—We have received a sample of a new cutting and polishing powder—the "Champion." We are informed that it is a Victorian product, entirely devoid of chemicals, and that it can be sold in London at lower prices than emery. It is stated that a quantity was sent to a mill in Melbourne to be ground in an ordinary emery-grinder, when "it was discovered that it ground the machine"; and that it has been tried and adopted by the Victorian Railway Department and by the Melbourne Tramways Company. Mr. F. M Pearson, of 8, Danes-inn, Strand, London, W.C., has been appointed European agent for the material.

Kingswood (Glos.).—The Urban Council have received a letter from Mr. White, on behalf of the tramways company, asking permission for the electric line to be extended down Warmley-hill to where the company had acquired property that they intended to use for car accommodation, etc. It has been resolved to agree to the company's request, provided (1) that they give an undertaking within a given period (not later than one year) to carry passengers on this extra line; (2) to give to the proposed new double line an equal width on each side, as higher up in Kingswood; (3) that they agree to pave the route with wood should the side of the road be paved at any time in that way.

Folkestone.—The Town Council have considered a report from the Special Electric Lighting Committee upon the letter of Mr. Medhurst requesting payment of his account for his report on the electric lighting of the borough, amounting to £55. 18s. 1d. Councillor Baker remarked that the Corporation would have to make application for a provisional order, otherwise a company would do so and take the electric light out of their hands. He thought they did not want to pay Mr. Medhurst till they had made their application. The Mayor said he was afraid that they could not deal with it, and the meeting ended, it being understood that an early meeting of the committee would be called.

Swindon.—The Finance Committee of the Corporation have passed for payment the following accounts in respect of the electric lighting order obtained this year: Messrs. Martin and Leslie, parliamentary agents, £237. 2s. Their total bill amounted to £252. 15s., being £90. 13s charges, and £162. 2s. payments; but they agreed to accept £237. 2s. in settlement. Messrs. Kinneir and Co.'s bill was £99 1s. 6d.; being £94. 4s. charges and £4. 17s. 6d. payments, but they agreed to accept £57. 7s. 6d. in settlement. Mr. Adams, in moving the adoption of this report, remarked that it was very kind of their clerk to make such a reduction in his firm's charges, and also to induce the parliamentary agents to adopt a similar course. The report was adopted.

Bennett and Druce.—Amongst the more recent installations carried out by Messrs. Bennett and Druce, of Preston, are comprised the lighting of eight large sheds at the Salford Docks, the lighting of St. Joseph's Catholic Church (with gas-engine, dynamo, and battery), the lighting of Colonel Ormrod's mansion at Scorton, together with a complete set of cooking and heating apparatus, the fitting of a 15-h.p. electric hoist at the Preston Co-operative Society's warehouse, and the lighting of Messrs. Pyke's corn mills at Preston. The above comprise a total of about 3,000 lights, mostly with engines, dynamos, and storage batteries, and in one case a 15-h.p. boiler, besides numerous smaller installations in various parts of Lancashire. The firm have recently opened a branch office in Belfast.

Leeds.—"It has long been a mystery," a correspondent says, "why the Corporation has not extended the service of the Roundhay electric cars into Briggate. The Roundhay Park line was laid down many years ago at an enormous expense, with the express intention of increasing and cheapening the facilities for getting to the park, and after a long and animated discussion as to the relative merits of overhead railway and tramway. The latter won the day, but after all these years of anxious waiting we are no better off as regards reaching the park cheaply and expeditiously than if the line had never been made, whereas had the Corporation arranged for extending the electric lines into Briggate we should have had a splendid opportunity of judging the merits and defects of the electrical system, and the desirability or otherwise of extending it to the other parts of the city."

Sunderland.—The electric lighting of the Ryhope Lunatic Asylum of the Sunderland Corporation is now completed. About 700 incandescent lamps are employed, supplied by a generating plant consisting of two direct-coupled Belliss engines and Parker dynamos. Steam is furnished by three Lancashire boilers, which also supply the service by means of which the building is warmed. There is also a battery of D.P. accumulators. The laundry machinery is driven by an electromotor, and there are several

Digitized by Google

other motors employed for ventilation and for distributing the hot air by which the various wards are heated. Messrs. Edmundsons, Limited, were the contractors for the whole of the electrical installation, while the boilers and heating apparatus were supplied by Messrs. Ashwell and Nesbitt. The electrical installation has been carried out under the superintendence of Mr. G. T. Hine, the architect, and of Mr. A. A. C. Swinton, the consulting engineer.

Derby.—Considerable activity is manifested at the electric lighting installation at Derby, every effort being made to complete the erection of the new coal store and the annexe to the motor-room before winter sets in. Three new boilers, each weighing between 20 and 30 tons, have been ordered, and two of them have already been delivered. It is hoped that they will all three be in working order during the winter. The annexe is being built to make room for a new 250-h.p. motor, which is much needed—the number of consumers having reached 194, whilst several others are waiting to be connected. At present the installation lights over 12,000 incandescent lamps nightly. The demand has for some time exceeded the supply, and it is quite evident that next spring further extensions will be necessary. The demand for current for motors on private premises is rapidly developing. With regard to the finances it is asserted that at the present time—indeed, during the last few months—the undertaking has assumed an increasingly prosperous position, and that even now it more than pays interest on the outlay.

Isle of Man Tramways.—A number of influential Manx capitalists have had under consideration the advisability of constructing a tramway between Douglas and Kirk Braddan. A firm of eminent Glasgow engineers, it is stated, have had a representative at Douglas taking the bearings of the route, and the promoters of the scheme are assured that no engineering difficulty stands in the way of the working of either a cable, electric, or horse tram service. Mr. S. H Emmett, the chairman of the Douglas Head Marine Drive, Limited, has issued a circular to the shareholders announcing the completion of the drive; that the whole of the land is paid for, and that there is cash in hand or owing which will more than pay the company's debts, debenture interest excepted. The directors have arranged for an electric tramway on the drive, and a separate company is being formed to work the tramway. The directors intend to offer Drive shareholders a preferential right of allotment in the new company. The directors point to the Laxey tramway as an instance of the success attending electric traction.

Liverpool.—Application has been made to the Health Committee, on behalf of the Post Office authorities, for permission to erect poles for telephone wires in Pellew-street, Great Newton-street, and Crown street. Mr. Morgan moved that the request be granted. The Government, he said, were expending more than one million pounds in their endeavours to cheapen telephonic communication, and this concession would certainly be to the advantage of Liverpool. Mr. Taggart considered that the wires should be placed underground. Mr. Morgan replied that this would mean a very great increase in the cost. Mr. Taggart remarked that overhead wires were always dangerous. Mr. Morgan pointed to the immunity from accidents hitherto, and said there was no reason to suppose that the danger would be increased in the future. This was simply a temporary arrangement in order to carry out the Act of Parliament passed some years ago. Mr. Menlove, after examining the plan, said he saw that no obstruction of the parapet would be caused. The motion was seconded by Dr. M'Cann, and was carried by five votes to three.

Bath.—Alderman Sturges, at the Urban Sanitary Authority meeting, moved the following resolution, which he explained was only a formal one and in consonance with the one which they passed on January 14: "That the application of the City of Bath Electric Lighting and Engineering Company, Limited, for a provisional order be not consented to, and that the authority apply to the Board of Trade for a provisional order under the Electric Lighting Acts, 1882 to 1890, at the earliest possible date." He said that although the course of action which they were to take was settled, the Electric Lighting Acts said that there must be a special resolution passed by the authority after a month's notice had been given. The notice of the resolution which he was to move on that occasion, in corroboration of what he had read, had expired, and he had pleasure in moving that an application be made by the local authority for the district of the city of Bath to the Board of Trade in the next session of Parliament for a provisional order under the Electric Lighting Acts, 1882 and 1888, authorising the said local authority to supply electric energy for public and private purposes within the district of the city of Bath. Mr. Morris seconded, and the motion was carried.

The National Telephone Company Summoned.—At Worship-street Police Court, on Tuesday, the National Telephone Company, Limited, was summoned by the sanitary authority of the parish of Spitalfields for allowing a nuisance to exist on their works, 39, White Lion-street, Spitalfields. Mr. Compton Smith, barrister, defended. Evidence was given by Alfred Cook, sanitary inspector of Whitechapel parish, that in consequence of complaints he enquired into the smells arising from the Company's premises, and found that in a shed at the rear of the premises a process of vulcanising the wires was carried on, and that there was a bath in which melted wax and sulphur were kept at a high temperature. The effluvium arising from the bath was said to be very objectionable. A witness named Wallis and a medical practitioner named Hume gave corroborative testimony as to the objectionable nature of the smells. The defence was that there was nothing in the process to cause offensive effluvia, and residents in the street and officials of the works were called to bear out the contention. Mr. Gripp, M.D., of Gower-street, said that he had been called in to examine and report on the work and could find nothing offensive in the process, but the street "was the most offensive he had ever walked down." Mr. Bushby reserved his decision.

Bolton.—The Chairman of the Board of Guardians has stated that the sub committee appointed to consider the question of lighting the workhouse premises by electricity had met, but were unable to agree. There were four gentlemen present, and two were entirely opposed to the proposal on economic grounds. Mr. Deakin was surprised to hear the result of the committee's work. He understood the majority of the Board were in favour of electric lighting, and moved that it be an instruction to the committee to take steps for that purpose. Mr. Rothwell seconded. Mr. Brocklehurst thought they ought to have had notice on the agenda that the matter was to come before the Board. There was no occasion for undue haste, and a great many members were absent. There ought to be some kind of report furnished by the committee to the Board, and he moved as an amendment that the matter lie over for a fortnight. Mr. Leyland seconded the amendment. Mr. Shaw was in favour of the offices being lighted by electricity. The Chairman said the sole objection to the electric light was on economic grounds. They could not pretend to ask firms to estimate if they had not decided to adopt the electric light. He had some experience in the matter, and it would not cost more than £150. The amendment was eventually carried, Mr. Deakin being prepared to postpone the question.

Aberdeen.—In connection with the forthcoming "at home" at Trinity Hall, the home of the Incorporated Traders of Aberdeen, a meeting of Dr. Guild's managers has taken place, a correspondent says, for the purpose of witnessing the inauguration of the electric lighting of the buildings. The installation, which has been fitted up by Messrs. P. C. Middleton and Co., Schoolhill, Aberdeen, consists of upwards of 150 lights, of from 8 c.p. to 50 c.p., and the result is extremely satisfactory. The fittings are considered to be the finest in the city, and it may be mentioned that the general lighting arrangements have been based on those adopted at Birmingham Town Hall, one of the places visited by the convener, the master of hospital, and other members who composed the deputation that went south some time ago. In the large hall the principal light comes from a very handsome hammered brasswork electrolier of 25 lights, depending from the centre of the ceiling. Near the corners of the ceiling are four smaller electroliers of 10 lights each. Ample light is thus provided, and the decoration of the fine building is seen to the best advantage. The minor hall is illuminated by two electroliers of 10 lights each. The vestibule, staircase, and the various rooms are also brilliantly illuminated, and the effect on the walls and pillars, consisting of six different kinds of marbles, is remarkably fine.

Swansea.—At Tuesday's meeting of the Swansea Town Council there was considered a recommendation that £56,000 be spent on the erection of plant for lighting the town by electricity and for destroying the town refuse. In certain sections a great outcry has been raised on the ground of expense and the inadvisability of going in for the electric light till the light has got nearer to perfection. On this question the Swansea borough surveyor (Mr. Bell), who has considered the question for years, has been interviewed, and he expressed confidence that not only will the scheme pay, but that there will be a profit of a couple of thousand a year after the first three years. There is estimated a revenue of £7,608 from public and private lighting, and against this there is placed the expenditure, including maintenance, capital shares, etc., at £5,798, leaving a balance of £1,810; add to this the £400 saved by the disposal of refuse, and there is £2,210. Sight must not be lost of the fact that unless the Corporation lay down the plant, and that soon, the work will be done by private individuals, who will have the profits instead of the ratepayers. Mr. Bell gives Taunton, Portsmouth, and Brighton as illustrations of the success of the light, where the streets are almost as brilliantly lit at night as daylight. Questioned as to the experience of Cardiff, he said the defects there were due to the engines failing to govern properly. The system recommended for Swansea is that which Mr. Manville thought best—that in use at Portsmouth—the high-tension alternating system, which the Electric Lighting Committee, after careful consideration, also think the best. The Town Council will consider the committee's recommendations at a special meeting on October 1.

Brandon (Durham).—The surveyor (Mr. R. Gardner) has presented to a special meeting of the Brandon and Byshottles Urban District Council a scheme and estimate of cost for lighting the district with oil and gas lamps. The Chairman said that they were not bound to accept the scheme proposed by the surveyor. In that case he thought they might take into consideration the question of lighting by electricity. In the district of Brandon there was a large volume of waste steam at the various collieries, especially at nights and at the week end, and he had an idea that this might be utilised for the generation of electricity for lighting purposes without incurring a single farthing of cost on the owners, and, moreover, he was of opinion that to use surplus steam in this way would relieve the strain on the boilers which ensued through the excessive heat from the coke-ovens, which, as most of them knew, supplied heat for steam-making. If the colliery owners would meet them in this matter, he felt assured that they would not only benefit the community, but further an arrangement of considerable value to themselves. Mr. J. J. Lishman did not think the colliery companies would supply steam, as suggested, for nothing. Eventually the following resolution was unanimously adopted: "That the Corlett Electrical Engineering Company, of Newcastle, be requested,

Digitized by Google

under the instructions of the chairman and surveyor, to report upon and estimate for the lighting by electricity the main roads and streets of the Council's district." A further resolution, that each of the several wards in the district call upon the colliery owners in their wards and ascertain how far they would assist the Council in the matter of lighting the district with electric light, was also carried unanimously.

Wandsworth, S.W.—The District Board of Works have considered a letter from the Brush Electrical Engineering Company, with reference to repairing trenches after the laying of electric light mains in this district, and recommended that the company be informed, in reply, that the paving disturbed by them will be made good by the Board promptly upon the trenches being filled in. The Wandsworth Committee recommend that the plan of the proposed electric light generating station at the Causeway, and of the works in connection therewith, be approved subject to an agreement satisfactory to the committee being entered into between the Board and the electric lighting company, with regard to the use of the proposed way by the Board for vehicular traffic to the Feathers Wharf upon payment by the Board of one-sixth of the cost of repairing such way, the provision for outfalls on the river, etc.; that the plan of the proposed drain from the generating station to the sewer be approved, subject to the right of the Board to connect a drain from the Feathers Wharf to the proposed drain without charge; and that the Board do all in their power to assist the company in obtaining the consent of the London County Council to the plan, and the consent of the Wandsworth Vestry to the proposed diversion of the Causeway. With reference to the letter from the Royal Wandsworth Laundry stating that the stopping up by the electric lighting company of the flow of the mill stream near their premises at Bell-lane causes a greater quantity of water to pass through the creek, and enquiring whether the Board have taken into consideration the possibility of their premises being flooded in the event of very high tides and heavy rains—that they be informed that the Board have no power to interfere in the matter, and that they be referred to the electric lighting company.

Killarney.—The recent audit of the Town Commissioners' accounts by Mr. J. Calvert, public auditor, raised the important point whether a corporation could keep going two systems of lighting—gas and electricity—at the same time. Mr. Moriarty, who appeared for the Commissioners, contended that it was competent to the Commissioners to try the two systems of lighting in the same way the London or any other corporation did when a new light, as the electric light was, came in. Killarney was a tourist route, and not merely a town of 5,000 inhabitants situate in a remote district, and it was therefore fairly entitled to a greater degree of light. There was nothing to prevent the Commissioners from trying both the gas and the electric lights, and he asked that before the auditor decided on surcharging he should hear some evidence on that. The Auditor said the first question he would decide was: Was it in the interest of the ratepayers to have both lights? He was perfectly clear from his own knowledge and observations that one light was necessary for the town. After some discussion on the legal validity of the contracts with the gas and electric lighting companies, the Auditor announced that he would give his decision in six weeks.—The Governors of the District Lunatic Asylum have passed the following resolution: "That we request the Board of Control to accept Messrs. Ferguson and Co.'s tender (£957) for the installation of the electric light in the asylum, if they give satisfactory security for the performance of their contract, but that before accepting any tender we request the Board of Control to furnish us with a copy of the contract to be entered into with the Killarney Electric Light Company for the supplying of the electric current." The Board of Control forwarded 20 tenders received by them for the installation of the electric light. They varied from £3,195 to £957. The consideration of them was deferred until Mr. Leake, the electrical engineer, was in attendance.

Sheffield.—A correspondent writes: At the Empire Palace of Varieties, which is rapidly approaching completion in Pinstone-street, the electric lighting company are busily engaged in wiring the building for the supply of the Palace, which is to be lighted throughout by electricity. The light will be controlled from a switchboard on the stage. The sunlight will be formed by 20 lamp pendants from the rim of the circular sliding roof, all festooned together, giving a light equal to 640 candles. The intermediate portion of the ceiling will be lighted by 10 ceiling lamps, giving a light of 320 candles, and the remaining portion of the ceiling by 10 three-light brackets, projecting from 10 ornamental shells, and giving a light of 480 candles. The decorative fronts of the dress and upper circles will be lighted by ornamental three and two light brackets, giving a light of 480 candles. The whole of the above light can be raised to full brilliancy or lowered, as required for stage effects. The entrances staircases, lounges, smokerooms, corridors, offices, etc., are lighted by a variety of pendants and brackets of an ornamental character, representing light of something like 3,200 candles. The shelter over the pavement in Upper Charles-street and Union-street will also be lighted, and above these will be suspended six arc lamps of 2,000 c.p. each. The stage will be illuminated by four suspended battens, each containing lamps, giving a light equal to 1,280 candles, proscenium and footlights equal to 2,000 candles, making a total light of 7,520 candles on the stage. The whole of the stage lights are arranged to give white, red, and green lights, and all can be lowered for stage effects. Stage arc lamps will be used, similar to those in use in most of the London theatres, instead of limelight. The work is in the hands of the Sheffield Electric Light and Power Company, Limited, under the personal supervision of Mr. A. Lucas and Mr. C. Furness, and similar lines have been followed to those found so successful at the Alexandra Theatre, which work was also executed by this company.

Hastings.—The following communication has been addressed to a local paper: "We saw in the report of the Hastings Gas Company, published in your issue of the 7th inst., that Dr. Gray is said to have stated that for electricity to compare favourably with gas it must be reduced in price to 3d. per unit. Although we have never actually tested the light-giving properties of Hastings gas as compared with electric light, we had always understood, from experiments that had been made in other towns, that with gas at 3s. per 1 000 cubic feet, and electric light at 6d. per unit, the total cost for a given amount of light would be practically the same. In order to see which of these statements was correct, we have had fitted up at the works seven Bray gas-burners on one side of a room, and a 200-c.p. Ediswan electric lamp on the other side. By means of a Bunsen grease-spot photometer the light was adjusted until it was equal from each source. These were left burning for two hours, from 9 p.m. to 11 p.m., and careful measurements taken of the gas and electricity consumed. It was found that 142·2 cubic feet of gas had been used; this, at 3s. per 1,000 cubic feet, is about 5d., whereas the electricity meter showed that only ·76 unit had been used. In order to bring the total cost up to the same as that of the gas it will be necessary to reckon the electricity at 6½d. per unit instead of 3d., as stated in the gas report. Dr. Gray will be interested to know that several of our customers will not pay on an average more than 6d. per unit for their current used during this half-year, whereas many, profiting by our new system of charging, are replacing gas lamps with electric lamps, for which they will not pay more than 4d. per unit for the current used. From this it is obvious that in many cases it will be necessary for the gas company to further reduce the price of gas to 2s. per 1,000 cubic feet before they can compare favourably with the present price of electricity. We shall be pleased to repeat the above experiments in the presence of Dr. Gray or any others whom they may interest.—L. ANDREWS, managing engineer to the Hastings Electric Light Company."

Llanelly.—The clerk read the following letter at the meeting of the Borough Council: "New Dock, Llanelly, September 9, 1895.—Dear Sir,—We should be glad to know whether your Council would be prepared to dispose of their provisional order for lighting Llanelly, and if so, on what terms? You are, of course, aware that we have given notice that we intend applying for a provisional order ourselves, but it might suit our purpose equally as well, and, since you have now declared your intention not to proceed with your own order, suit you also, if we were to acquire your order.—Waiting your reply, we remain, yours faithfully, J. C. Howell Limited." The Clerk explained that on the receipt of that letter he had written to Messrs Howell asking what they would be prepared to offer. He received a reply to the effect that they would prefer knowing the terms of the Council. The Chairman asked what were the terms of the provisional order. The Clerk explained that the order would not expire until it was rescinded by the Board of Trade. The Council, according to it, were supposed to light the town before the expiration of a certain period. But this order was not like an ordinary Act of Parliament, and they were not bound to carry out its provisions. The Chairman said the question was whether they would hand over the powers to private enterprise. They must not act upon the dog-in-the-manger policy. Mr. Maybery did not see much objection to disposing of the order. The Clerk, in reply to a question, said that the order cost the Council a sum of £223. Mr. Guest: Would it be worth asking that for it? The Clerk said that supposing Messrs. Howell applied for a provisional order, and the Council opposed it, what would be their position? Providing there was no opposition, it would cost them about £250 to get. Mr. Guest asked if in selling the order they could not keep a few of the clauses to themselves? Mr. Thomas wanted to know if the Council could part with the order, and dispose of it to a private company? The Clerk said they could grant a license, subject to the consent of the Board of Trade. It was ultimately decided that the clerk should report upon the matter at the next meeting.

Worksop.—The following letter has been forwarded to the chairman and councillors of the Worksop Urban District Council, Worksop, Notts.: "Gentleman,—As an engineer who has taken up residence in Worksop within the last year or so, on account of the town being a more healthy and pleasant neighbourhood than Sheffield, it has seemed very clear to me that there is considerable room for improvement in the appearances and conveniences of our town. I, with several others, am of opinion that what we require first is light—more light—and, if possible, cheaper light, and with this in view I am attempting to form an electric light and power company here. With this end in view, I have acquired a very suitable piece of land in Bridge-place (opposite the cattle market) from Sir Henry Watson upon most reasonable terms, which I am prepared to transfer to the proposed company without profit. I hope this scheme will meet with the approval of your Council, and will be encouraged by you, so far as lies in your power. I may say that I have two schemes whereby the electric current can be used as power, with a good profit, and shall be able to guarantee that nothing will be done in connection with the company's works that will be in any way offensive to the neighbourhood. In the first place, I anticipate that the current will be taken up by manufacturers, hotel and shop keepers, and householders, who are anxious to preserve their wares, house fittings, and decorations from the ill-effects of burning coal-gas. In the second place, I have good evidence that the railway company will take the current to light the Worksop goods and passenger stations when I can show them

Digitized by Google

that a substantial company has been formed. The Council will at once see the advantage it will be to Worksop to have a well-lighted railway station and approach thereto. In the third place, I anticipate that your Council will be pleased to take the current for lighting the Town Hall and principal thoroughfares, as I believe they will be well supported by the Worksop people in doing so. The advantage of having your assembly-room in the Town Hall lighted up by electricity for public and recreation meetings cannot be overrated, and the lighting of the main thoroughfares from the railway station to the Worksop Manor gates by the current will well deserve the consideration of the Council. Your approval of the scheme will, I feel sure, be favourably greeted by the inhabitants of Worksop and district.—Yours, etc., THOMAS NASH."

Hampstead.—The Lighting Committee reported at the last Vestry meeting that they had empowered the vestry clerk to take all necessary proceedings against the London and Hampstead Battery Company for non-compliance with the by-laws made by the London County Council under the London Overhead Wires Act with reference to the wires placed by them over and along the public streets in this parish. A letter was received from the solicitor of the Vestry reporting the result of a summons against the company, stating that the company admitted they were in default, and that upon payment of the costs, the summons was withdrawn, the Battery Company undertaking to comply with the by-laws within seven days. The Lighting Committee reported that they had empowered the engineer to order another plant, similar to the large unit at present in the station, at the estimated cost of £2,343, such sum including all expenses in relation to erecting the same in the station ready for actual use. The report was approved. The action of the same committee in empowering the engineer to order certain materials, etc., required was also approved. Amongst the articles were a number of house-service boxes at 35s. each. Mr. Johnson asked what price had been formerly paid for house-service boxes The Electrical Engineer: £3 16s. each, but they were not the same boxes as these. Mr. Colley explained that these cheaper boxes were to be tried as an experiment. The same commitee reported that they had given instructions that in the future no pupils or improvers would be allowed to be taken on at the station.—Approved. The same committee also reported that they had given instructions for the whole of the staff employed by the Vestry in their electric lighting undertaking to be insured in the Boiler Insurance and Steam Power Company, Limited, at the rate of 5s. per cent. on the annual wages paid, such rate including injuries arising from electric shock.—Approved. Instructions were given for an electric motor to be obtained for the chaff-cutting machine at the stone-yard, from the General Electric Company, at a cost of £24. 3s. 9d. On the motion of Major-General Young, it was decided to obtain and fix a Blackman electrical ventilator in the Board-room of the Vestry Hall. A letter was received from Mr. W. H. Preece, submitting his account for balance of commission for professional services rendered to the Vestry in connection with the electric light installation, amounting to £1,353. 18s. 6d. It was referred to the Finance Committee.

Bedford.—The Electric Light Committee of the Bedford Town Council have reported—(*a*) That the sanction of the Local Government Board has been given to borrow the further sum of £27,000 for electric lighting purposes, such sum to be repaid within a period of 25 years from the date of borrowing the same. (*b*) That acting upon the instructions of the authority they have given notice to the Bedford Gaslight Company, informing them that after February 6 next they will discontinue the use of the lamps in 67 public streets (*c*) That a communication has been received from the Bedford Gaslight Company, drawing attention to the system adopted in the extension scheme of laying the cables in stoneware culverts instead of in iron pipes. The committee, whilst fully appreciating the kindness of the company in drawing attention to the fact in the interest and safety of the public, would observe that the Council can with safety adopt the system of stoneware culverts. The system is now in use in Westminster, Edinburgh, Manchester, Sunderland, Bradford, and many other places, and the result is in every way satisfactory. (*d*) That they have much pleasure in stating that the demand for electric light is increasing. The committee recommend (*e*) that the engineer be empowered to procure iron pipes and cables for the high-tension mains to St. Mary's sub-station, and the remainder of the cables for the following streets—viz., Tavistock-street (to Adelaide-square), St. Peter's-street, St. Loyes-street, Harpur-street, Newnham-road, St. John's-street, St. Mary's-street, Cardington-road, and Cauldwell-street—and also the necessary switches, fuses, ammeters, and voltmeters for the station, and two additional transformers and fuse-boxes for the sub-stations. "The electric lighting in Bedford," says a Bedford contemporary, "has so far been very successful, and the promise of still greater success in the future is very encouraging. Early next year a great many of the streets will be lit by electricity instead of gas, and the cost will in time be defrayed out of the profits derived from the electricity supplied to private consumers. A great deal used to be said about taxing the inhabitants of back streets for the illumination of the main streets, on the supposition, we presume, that only the larger streets would be lit by electricity. Even if that supposition had been correct, the inference drawn from it would be incorrect, inasmuch as the dwellers in the back streets make as much use of the main streets as do other inhabitants of the town. The jealous criticism of the doings of the Electric Lighting Committee by persons who opposed the undertaking by the Corporation is not to be regretted. It will keep the committee up to the mark, and will be the means of frequently eliciting facts which will but the more completely justify the action of the Council."

Bristol.—With reference to the outbreak of fire in a transformer-chamber in connection with the electric light in St. James's, Barton, on Monday evening, it appears that the incident was quite an isolated one, and entirely connected with an experimental test. A *Bristol Mercury* reporter sought an interview with Mr. Faraday Proctor, the electrical engineer, to enquire the exact cause of the accident. He learned that the engineers were testing the new cables for the Stoke's Croft supply at three times their working pressure before permanently joining them up to the Stokes's Croft service, for which a cable runs into St. James's, Barton, transformer-chamber and then on again to the next sub-station at the bottom of Thomas-street, Stoke's Croft. For the testing purpose temporary wires were laid across the sub station from one end of this cable to the other to convey this extreme pressure, and as it was thought possible there might be some breakdown under such an extra current, the covers of the chamber were left off, and a man was left to watch while the pressure was on, and with directions to telephone to the central electric station if anything went amiss. Directly the pressure was got up at the works on Temple Back the small fuses there burnt out, and the foreman was immediately sent to the Barton sub-station. At the same time a telephone message was received that smoke was issuing from the manhole of the transformer-chamber. The temporary wires were fastened to some small pieces of creosoted wood, which also caught fire. These pieces of wood were for the purposes of fixing the wires, and, although there was a great volume of smoke, the engineers state that there was really no great body of fire, as there was little there to burn, and incandescent lamps burning there at the time of the occurrence had remained intact. The supply in Stoke's Croft, having been cut off for the afternoon for the purpose of joining up certain premises taking the light, could not be restarted until the men could get into the Barton sub-station. But after the fire the current was again turned on at seven o'clock at full power. There was a thin roof of match-boarding over the chamber for the purpose of fastening the cables, but the whole structural portion of the building is made up of Cattybrook brick walls 2ft. thick, concrete floors, and the floors or roofs 2ft. thick, and concrete and iron girder work. In addition there was a thin sheet of lead immediately covering the match-boarding, with the object of letting off any water which might leak through the concrete. Substantially, all the contents were fireproof with the exception of the match-boarding and the small pieces of wood already described. Thus there was nothing but this wooden portion to burn in Monday's mishap, and within half-an-hour the electrical engineer was enabled to descend into the chamber and inspect it. He found that the temporary wires together with the pieces of wood and match-boarding, were burnt away, but the two transformers and the high-tension boards and other apparatus were safe and intact, and the whole damage would be covered by a few pounds. Thus the local paper. Mr. Faraday Proctor informs us, by letter, that they have never had any explosion or suspicion of gas in any of their chambers, and that the new cables referred to (in Stoke's Croft) were tested to 6,000 volts on Wednesday morning, and found perfectly satisfactory.

Brighton.—A correspondent writes: The latest, and, from the point of view of the general public, most practical and interesting development of the Brighton Corporation electricity undertaking—namely, the illumination of the principal thoroughfares of the town by the arc system—is beginning to assume form and substance. For some weeks past the work of erecting the standards for the lamps has been in progress, and in all probability the new installation will be inaugurated in detail during November. When complete the installation will consist of 120 lamps, about 50 of the standards being similar in design to those on the King's-road for use along the Marine-parade chiefly, and the remaining 70 of the bracket pattern. These standards are according to designs prepared by Mr. May, the borough engineer and surveyor. The installation will extend the whole length of the Western-road, North-street and St James's-street, Queen's-road and West-street, Preston-street, East-street, the Old Steine Marlborough-place, and the London road to New England road. The lighting of the Marine-parade will also complete the line of lamps along the sea front, and two lamps will likewise be put up in Ship-street. Of the thoroughfares named, the Western-road, Queen's-road, and West street have been dealt with so far as relates to the somewhat obstructive work of setting up the standards, and North street and the Marine parade are now engaging attention. This application of electric light to public purposes within the town will necessarily add materially to the business and to the prosperity of the electricity undertaking; but really the progress of that undertaking has exceeded even the most sanguine anticipations of the strongest advocates of this addition to the responsibilities of the Corporation. Acting under the advice of their able manager, Mr. Wright, the Lighting Committee some time since introduced a differential rate, based on the hours of consumption, the effect of which in Brighton has been to reduce the average charge for the light to about 4¾d. per unit, a rate lower than that charged in any other town, with the exception of Manchester, notwithstanding that the cost of coal is greater in Brighton than elsewhere. Imitation being the sincerest form of flattery, it is worth making a note of that this differential rate, known as the Brighton system, has been adopted at Bournemouth, Southport, Hastings, Blackburn, Coventry, and in other towns, Manchester having it also with modifications. The increase in the number of customers has

Digitized by Google

been from 157 in 1892 to 336 in 1893; 720 in 1894 to 970 for the year ended the 16th inst. Moreover, while in other towns the yearly supply of electricity has never exceeded three units per inhabitant, in Brighton in 1894 it was five units, and during the year just closed it was 10 units. The profit made last year was £9,800, or with the balance in hand £10,100, of which amount £5,014 was appropriated for the loan account out of which will eventually come the redemption of the undertaking which will remain a handsome legacy to posterity. The Lighting Committee of the Corporation have had before them a letter from Mr. J. V. Witting enquiring the terms for laying a supply of electricity to Hollingbury Copse, Ditchling road, Patcham, but the premises being outside the borough they resolved that they were unable to supply them with electricity. It was decided that a main be laid in Bedford-square, and that another be laid from Western-road as far south as Sillwood-road.

St. Pancras.—Messrs. Hancock and Dykes, of 5, Victoria-street, London, S.W., have addressed the following communication to the *Times*: "Within the last few days an innovation in the supply of electricity has been quietly introduced which may have a very marked effect on the future of electric lighting. The Vestry of St. Pancras have doubled the pressure at which they supply the current, and, although probably all supply companies will ultimately do the same, one is entitled to protest against the suddenness of the change in this case, as it is certainly prejudicial to the public interest. Very few of the manufacturers and others interested have been properly advised, and as there has so far been no demand for 220-volt fittings and appliances there are none on the market. Until a sufficient time has elapsed for suitable fittings to be designed and produced there will be a very grave risk of extinction, damage, and perhaps fire, on 220-volt circuits. As far as the lamps are concerned, 8-c.p can no longer be used; the 16-c.p. is the smallest size obtainable, and that is expensive, ugly, and altogether untried in performance. Time alone will enable the makers to perfect and produce what is required, and surely the authorities are not warranted in increasing the capacity of their mains, when in order to do so they sacrifice the public convenience, and perhaps safety, by not giving ample notice of their intention to make so radical a change." To this Mr. Sydney W. Baynes, chief engineer, St. Pancras Vestry Hall, N.W., has replied: "Had your correspondents applied to me at the Vestry Hall for information on this matter it would have been to their advantage, as they are evidently very far from being up to date regarding high-voltage lamps and fittings. It may interest them to know that I have had such lamps in constant use for 18 months, and for the past seven months they have been installed in the premises of customers supplied from one of the most prominent and successful stations in the country, with excellent results. No alterations in the fittings or wiring have been needed. The ordinary tumbler switch, good porcelain cut-outs, well-insulated wire, combined with good workmanship, have long since proved thoroughly efficient and safe in carrying even a still higher voltage than that to be introduced at St. Pancas. Eight-candle-power lamps at 230 volts are in the market, and Mr. Stearn the joint inventor with Mr. Swan of the incandescent lamp, is to the front with a high-voltage lamp of 6 c.p. Your correspondents could never have seen a properly-constructed 220 volt lamp, or they would not have stigmatised it as ugly, seeing that the best makers turn out a lamp in no outward respect different from the 110-volt lamp, which, like the original 50-volt, will in time become a matter of ancient history. Those who best understand the subject and its importance on the future of electric lighting are the most desirous of co-operating to render the movement I have introduced thoroughly popular and successful" Messrs. Hancock and Dykes replied on September 25: "We note Mr. Baynes's letter in your issue of to-day, which interests us, as we applied to certain well-known lampmakers and also manufacturers of fittings only a week ago, and they were no more up-to-date than we are. Surely it is scarcely right for a public body like the St. Pancras Vestry to recommend certain makers before other equally important ones have even been advised of their requirements. It should be added that our thirst for knowledge led us to make enquiries at the Vestry's Stanhope-street electric light station; but Mr. Baynes has evidently kept all these good things to himself, as the officials there surprised us by asking for the very information which we had come to seek. Our previous letter makes it tolerably clear that we also wish to see the movement succeed, but do not agree with the method of initiation. From our past experience with 220-volt installations we believe it to be the voltage of the future, but beg to repeat that in our opinion much of the existing wiring is unsafe at that pressure. With reference to the performance of the lamps, a trial will easily settle the question. If Mr. Baynes will choose 12 8-c.p. or 16 c.p. 220-volt lamps, we will also select an equal number of 100-volt lamps, these to be submitted to an independent expert for a comparative test as to life at a steady voltage and also with a voltage fluctuating 4 per cent. above and 4 per cent. below the normal, both sets of lamps to have an efficiency of 3·75 watts per British candle-power. We trust that Mr. Baynes will accept this challenge, as it will at once set the question at rest."

Nottingham.—In celebration of the anniversary of the installation of the electric light in Nottingham, an interesting function has taken place at the electric lighting station in Talbot-street. Invitations had been issued by Alderman Sir Jno. Turney to the members of the Electric Lighting Committee, the chairman of the Gas Committee (Alderman J. Barber, J.P.), and the officials of the Corporation to meet him at the works and inspect the machinery in operation. In response to the invitation, there were present: the Mayor (Councillor J. Bright), the sheriff (Councillor Dr. F. R. Mutch), Alderman J. Renals, J.P., Alderman F. Pullman, J P., Alderman S. H. Sands, J.P., Alderman J. Barber, J.P., Councillors R. Fitzhugh, J.P., J. T. McCraith, J.P., and W. Bailey the town clerk (Sir S G. Johnson), the borough engineer (Mr. A Brown), the electrical engineer (Mr. H. Talbot), the borough gas engineer (Mr. W. R Chester), the deputy town clerk (Mr. J H. Richards), the assistant borough engineer (Mr. T. B. Lewis). and the assistant borough accountant (Mr J. E. Bryan) Under the guidance of Mr. Talbot the visitors spent a pleasant half-hour in the examination of the works, which were pronounced to be in the most satisfactory condition. Alderman Sir John Turney said he thought it would be well some time ago to give gentlemen of the Council an opportunity of meeting the Lighting Committee. They would remember that when the station was finished there was no flourish of trumpets or opening ceremony. The committee felt that having undertaken this work, and it being a new venture, they had better run the work for a considerable time before they expressed an opinion about its value and its efficiency. Of course he had taken a great interest in electrical work from a general point of view for many years, and when the Council decided to appoint a committee to take seriously into consideration the supply of electric current for the people of the town, that committee devoted a considerable amount of time to visiting the various stations of the country with a view to arriving at what they thought would be the best plant to lay down. After doing that, and taking the advice of eminent electricians and engineers they decided to adopt what was known as the direct-current three-wire system. On that plan they had based their installation, and they believed that in doing that they had adopted the best plan, although in the neighbouring towns of Derby and Leicester there was an opposite condition of things—namely, the alternating system. The committee claimed that their system had advantages over the others. They could run their plant practically with one shift instead of having a double shift. They could give a continuous supply of current without being at the mercy of movable machinery. However perfect movable machinery might be, it was at times an unknown quantity, and when they were most relying upon it it failed them. Their engines were directly coupled with the shaft of the dynamo They had no large horizontal engines such as worked the alternating system. Their site as was well known, was very limited, and therefore they had to take that fact into consideration. Their engines were giving them about 640 h p The committee felt that in establishing the plant on the lines they had established it, and before talking about its efficiency having a year's working before them they had pursued a wise policy. They were justified in the course they had taken by the 12 months' working. He had figures before him which he thought would compare favourably with, or would be equal to, those of any electrical station, whether established by a corporation or a limited company so far as actual cost went. The total amount of capital they had invested in this undertaking at the present time was £48 633, which was divided in the following way: cost of site of station, £10 823; the building had cost £11,200; the machinery cost £10 286; the accumulators which they had just seen cost £1,421; the mains in the compulsory area which the Corporation decided to light cost £10,094, and since then they had to spend on extensions outside the compulsory area £3,751, and the meters had cost £911, and the electrical instruments, £147—making, as he had stated, a total of £48,633. The revenue account showed the following figures: Sale of current for three completed quarters—Christmas, 1894, £742. 1s. 3d; Lady Day, 1895, £854 14s. 10d.; Midsummer, 1895, £413. 8s. 8d.; a total of £2,010. 4s. 9d. Other receipts amounted to £80. 14s., the total revenue for nine months being £2,090. 18s. 9d. The total cost of generation was £1,383. 16s 4d., and the gross profit £707. 2s. 5d. The machinery had been built by the best makers, and had been put in under the supervision of the electrical engineer, Mr. Talbot, who was a most careful and painstaking man. There was no doubt that if they had had another winter quarter they would have been able to show better results, but, treating the concern as an ordinary company, they were able to show a profit of 2 per cent. on the undertaking. The number of consumers who had applied for current at the time the station was opened in September, 1894, was 35, but the number of consumers on the books at the present time was 148 He had not the slightest doubt that the results of another year's working would show greater profits on the outlay. They had to day over 12 miles of cable laid down in the town. This represented 12 months' work. They would doubtless have many more miles laid during the next 12 months. The Mayor said they had been greatly interested in the information imparted by Sir John Turney. He ventured to think that the Corporation adopted a very wise policy in waiting in order that they might gain the experience of other towns in the matter of electric lighting, or rather in the manner in which the electric light might be produced, and supplied in the most perfect style and most economical way. He believed the policy of delay was one which would be fraught with the greatest possible interest to the town. In his opinion it had also been wise on their part that, instead of handing over the supply of electric light to other individuals—to a limited company—the Corporation had retained the supply of electric lighting in their own hands. They complimented Sir John Turney upon the success of the enterprise so far as it had gone. When the buildings were completed it was contemplated presenting him with a gold key with which to open them. But since there had been no formal opening he had now very great pleasure in asking Sir John's acceptance of the key as a memento of the great work in which he had been engaged. Alderman Sir John Turney, in accepting the gift, expressed the pleasure which the work connected with

Digitized by Google

the committee had afforded him, and observed that if they were to keep pace with the times they ought to have electric tramways in Nottingham.

PROVISIONAL PATENTS, 1895.

SEPTEMBER 16.

17232. **An automatic and electrical tell-tale apparatus for indicating water and other liquid levels.** James Dixon, 209, City-road, London.

17249. **An improved gauge for gauging electrical and other wires, drills, boring bits, and other similar articles.** Albert Ernest Woodhouse, 7, Staple-inn, London (Complete specification.)

SEPTEMBER 17.

17283. **A method or system of utilising town's water for generating electricity.** Edgar Booth, Commercial-street, Halifax

17287. **Improvements in and relating to insulators for telegraph and telephone poles.** William Dibb and Albert Vickers, 17, St. Ann's square, Manchester. (Complete specification.)

17288. **Improvements in and connected with the electrolytic decomposition of alkaline salts.** William Adolph Rosenbaum, 70, Market-street, Manchester. (Complete specification)

17290. **An adjustable support for electric lamps or similar fixtures.** George Davis, 4, St. Ann's square, Manchester. (Otis Converse White, United States.) (Complete specification)

17296. **Improvements in ships' or navigable vessels' mechanical telegraphs.** Albert Edward Seaton and William Henry Willatt, Wilton House, Holderness-road, Hull.

17328. **Improvements in electrical attachments for playing pianos.** George Houlett Davis 45, Southampton buildings, Chancery-lane, London. (Complete specification)

17330. **Improvements in electric exploders** Herbert Vivian Keeson, 40, Loudoun-road, St. John's Wood, London.

17365. **Improvements in and relating to automobile cars for electric railways.** Reginald Belfield, 31, High Holborn, London.

SEPTEMBER 18.

17400. **Improvements relating to permanent way, electric conduits, and conductors of electric tramways.** John Thomas Wood and John Alexander Brodie, 26, Castle-street, Liverpool.

17430. **Improved methods of and means for making and breaking electric circuits.** Reginald Belfield, 31, High Holborn, London.

17436. **Improvements in thermo-electrical generators and the method of operating same.** Harry Barringer Cox, 46, Lincoln's-inn-fields, London (Complete specification)

17442. **Improvements in electric resistances.** Leicester Bradney Stevens, 40, Chancery lane, London. (Complete specification.)

SEPTEMBER 19.

17479. **An improvement in connection with electric pushes for hall or other doors which may be used in connection with or replace existing door-knobs, handles, or pushes.** C. P. J. Fitzsimon, 1, George's-avenue, Clonliffe-road, Drumcondra, co. Dublin.

17481. **Improvements in electrollers.** Robert Hall Best, 18, Southampton-buildings, Chancery-lane, London.

17495. **Electrical heating apparatus.** Victor Isidore Feeny, 60, Queen Victoria-street, London. (H. W. Johns Manufacturing Company, United States.) Complete specification.)

17505. **Improvements in electrodes.** Carl Hoepfner, 45, Southampton-buildings, Chancery-lane, London.

17507. **Improvements in and relating to electric cables.** Jean Graizier, 45, Southampton-buildings, Chancery-lane, London.

17510. **Improvements in electric current meters.** Robert Hacking and George Brand, 78, Fleet-street, London.

17525. **Improvements in the electrolytical manufacture of bleaching liquid.** Carl Kellner, 46, Lincoln's inn fields, London

17526. **Improvements in electrical transformers.** Arthur Francis Berry, 46, Lincoln's-inn-fields, London.

17528. **A new and improved electro-deposition, more especially applicable to electro-plating.** Alfred Francis Bilderbeck Gomess, 9, Warwick-court, Gray's-inn, London.

17529. **Improvements in arc lamps and in stands therefor.** Benjamin Joseph Barnard Mills, 23, Southampton-buildings, Chancery-lane, London. (Edward Powell Hopkins, United States.)

SEPTEMBER 20.

17603. **Improvements in electric batteries.** Michael Martin Bair, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

17573. **Improvements in electrolysis.** Graydon Poore, 9, Quality-court, Chancery-lane, London.

SEPTEMBER 21.

17634. **Improvements in and relating to incandescent electric lamps.** William Henry Soulby, 2, Old Market-chambers, Yorkshire-street, Rochdale.

17655 **Improvements in secondary batteries.** Bernard Mervyn Drake and John Marshall Gorham, 66, Victoria-street, Westminster.

17656. **Improvements in spring contact switches.** Bernard Mervyn Drake and John Marshall Gorham, 66, Victoria-street, Westminster.

SPECIFICATIONS PUBLISHED.

1887.

4225.** **Electricity meters, etc.** Hookham. (Amended specification.)

1892.

15887 **Obtaining metals by electrolysis.** Frei. (Second edition.)

16300. **Supplying electricity to carbon electrodes.** Frei. (Second edition.)

1893.

10298. **Dynamo-electric machines.** Sayers (Second edition.)

1894.

14765 **Electrically reproducing graphic matter or designs.** Williams

18501. **Incandescent electric lamps.** Ker.

20397. **Arc lamps.** Creffield.

21142. **Electromotors.** Siemen Bros. and Co, Limited. (Siemens and Halske.)

21827. **Dynamo-electric generators.** Imray. (Société Anonyme pour la Transmission de la force par l'electricité.)

24934 **Electric switch.** Wagg.

1895.

57. **Ascertaining difference of electrical potential.** Hopkinson.

3548. **Electric switch.** Edge.

13434. **Electrolytical production of zinc.** Siemens Bros. and Co, Limited. (Siemens and Halske)

14481. **Imitation candles for electric lights.** Poole and Lowry.

NOTES.

The Telephone in Western Australia.—A telephone exchange is shortly to be established in Coolgardie.

Telephones in Mexico.—A telephone line is to be established between Ario and La Huacana, in the State of Michoacán.

The Telephone in Germany.—On September 25 telephonic communication between Berlin and Königsberg, in Prussia, was established. The charge for a conversation of three minutes is one mark.

Telegraphs in Siberia.—A telegram from St. Petersburg states that a telegraph line is to be established between Bachta and Tchugutscheek in Siberia, which will primarily facilitate telegraphic communication with Western China.

Electricity on the Brooklyn Bridge.—At a recent meeting of the trustees of the Brooklyn Bridge a resolution was passed instructing the chief engineer to "investigate the subject of electric motive power for the propulsion and switching of trains on the bridge."

Society of Engineers.—The next ordinary meeting of this society will be held at the Royal United Service Institution, Whitehall, on Monday, October 7, when a paper will be read on "The Relative Value of Percolation Gauges," by Mr. Reginald E. Middleton.

The Berlin Exhibition, 1896.—The Working Committee of the Berlin Industrial Exhibition of 1896 request intending exhibitors to immediately inform them of the exact amount of light and power, either electrical or gas, which they will require. Replies must state the number of 16-c.p. incandescent lamps, and of 500-800-c.p. arc lamps needed.

City and Guilds of London Institute.—At the recent matriculation examination of the City and Guilds Central Technical College, 76 candidates presented themselves, and 62 have been admitted to the college. The highest place was taken by M. Solomon, to whom the Clothworkers' scholarship of £60 a year and free education has been awarded.

Proposed New Atlantic Cable.—According to the *Figaro*, M. Lebon, the French Minister of Posts and Telegraphs, has announced to the members of the Calais Chamber of Commerce that he has signed a contract for the laying of a submarine cable from Brest to New York, which will be connected with the French telegraph system in the Antilles. The contract, which bears a large number of signatures, will, it is said, be presented to the Chambers when they reassemble.

Electric Railways in Peru.—It is announced that a representative from the Baldwin Locomotive Works, and an expert electrical engineer from the Westinghouse Company, together with Sir Henry Tyler, ex-president of the Grand Trunk Railway, have left for Peru, where a test of the possible powers of the electric locomotive is to be made upon a railway 15,000ft. above the sea-level. Sir Henry Tyler, it appears, was recently in Philadelphia in conference with members of the Baldwin firm on the subject.

Accumulator Traction in Germany and Holland. The *Kölnische Zeitung* announces that experiments in Hanover with accumulators (rapid-charging system), for traction purposes have given such satisfaction, that the tramway company of that city has resolved to adapt 28 cars, at present used with overhead conductors, for the reception of storage batteries. The paper states, moreover, that the Dresden Tramway Company and the Hague Tramway Maatschappy have also decided to try accumulator traction.

The Pacific Cable.—Colonel Spaulding, who lately acquired from the Hawaiian Government a license to lay a cable between the Sandwich Islands and San Francisco, is at present in Washington, and at an early date will, it is said, submit a proposition for the cable, and will ask for aid from the American Government. Colonel Spaulding expects to get private subscriptions to the amount of 1,000,000dol., and he anticipates that the United States Government will furnish the balance.

The Cattori Electric Railway System.—A Roman commercial paper—the *Bollettino delle Finanze*—has printed a long account of a system of electric traction devised by a Captain Cattori, in which neither underground nor overhead conductors are used, "the current, without inconvenience of any sort, and with perfect safety for the person, being conveyed upon the rails serving for the traction. The distribution of the current is made in series, the two rails forming a sole conductor, the return being through an overhead wire" (!)

The Durability of Asphalte Cables.—Herr Görz, of St. Petersburg, writing in the *Elektrotechnische Zeitschrift* on the proposed German wiring rules, and suggesting several amendments, refers to the question of the durability of insulated cables. He states that the whole underground network of the St. Petersburg electric supply station consists of lead-covered asphalte Siemens-Halske cables, which have been working for the last six or seven years to entire satisfaction. The expenditure for repairs and renewals for the past year was only ½ per cent. of the total expenditure of 1,100,000 silver roubles on cables.

"The Coolest Place in London."—The management of the City and South London Railway is nothing if it is not ingenious. During the recent spell of sweltering weather, in order to attract passengers it hung huge placards outside the various stations announcing the fact that "the electric railway is the coolest place in London." The officials say that the announcement has had a great effect, and that during the past week men of Falstaffian proportions, who perspire painfully, or as the Shakesperian phrase hath it, "lard the lean earth," have spent the best part of their afternoon in travelling to and fro in the coolest place in London. The summer heat has, of course, hitherto been considered to be the bugbear of the subterranean undertaking.

The Spanish Telegraph Service is being hotly attacked again. In a recent article, entitled "Disaster Approaches," *El Telegrafista Español* says: "All the Madrid and a considerable portion of the provincial Press, without distinction of party, have entered upon a campaign, none the less energetic for being brief, against the telegraph service, which is not a service because its constitution renders that impossible; nor is it a *renta* (revenue), because that could not be the case in this country, where the word *renta* is understood in the sense of impost, duty; and," adds the journal, "the Press is quite right." It is well to note, turning to a more peaceful subject, that the Madrid Tramway Company has requested license from the authorities concerned to substitute electric for animal traction on its principal lines.

Electric Keno.—A new game of chance has been devised, in which the ordinary electric fan plays an important part. The only requisites are the "current" and a goodly supply of small coins. The rules governing the game are simple. Each of the blades is numbered, the numbers running from one upwards. A corresponding set

Digitized by Google

of numbers and small circles is marked on a sheet of paper, and the game proceeds. Each player covers a number with a coin, the current is turned on, and the fan buzzes gaily for a minute. Then it is suddenly shut off, and as the revolutions grow slower, every player watches to see which blade will be uppermost, the centre of the screen having been marked. The man who covers that number wins all the money, the numbers are again covered, and away goes the fan on another whirl.

"Queer Crankism" of Electricity.—A Boston journal says that "North Adams continues to be puzzled over a queer crankism of electricity in its vicinity. Although when the great 4½-mile Hoosac tunnel was built no ores, magnetic or otherwise, were encountered, there was general expectation that rich ore pockets would be found, yet for an unexplained reason not an electrician has been discovered who can send a telegraphic message on a wire running from portal to portal of that tunnel, be such wire run inside of an ocean cable through the huge cavern or out of it. Therefore, such messages have to be sent on wires strung on poles over the top of the mountain, fully nine miles, and that is the way ingoing and outgoing passenger and freight trains are heralded to the keepers of the two tunnel approaches."

The Utilisation of Finnish Waterfalls.—The Russian Ministry for the Interior has been applied to for the granting of a concession for the formation of a limited company to utilise the famous waterfalls of Imatra and Narva. The plan comprises the transmission of the electric power to places at a considerable distance, both for factories and for electric lighting purposes. The scheme embraces not only Finnish towns, like Viborg, Helsingfors, and others, but also St. Petersburg, Riga, Reval, and still more distant places. The Russian authorities are understood to view the plan with favour, although in engineering circles it is hardly considered feasible. As the capital required would be larger than what the promoters consider it possible to raise in Russia, it is contemplated to try and interest foreign capitalists in the undertaking. The Finnish Senate have been requested to give their opinion in reference to the scheme.

Electricity in Mines.—At a recent meeting of the German Miners' Council at Hanover, a communication was made by Herr Doeltz, mining assessor, of Hanover, on the employment of electric transport in mining work. The power developed by electric currents, the difference between continuous and alternating currents, the employment of electric motors for accelerating work, and the strength of conductors were illustrated by drawings. Superintendent-engineer J. Körting-Körtingsdorf spoke on the application of gas motors to transport work. Steam power would cease to give satisfaction now that electric power and gas-engines had been taken up. Small steam-engines had already been everywhere replaced by the latter; gas-engines had also recommended themselves to the needs of large decentralised businesses; the best results would be obtained by the combination of gas power with electricity.

The Electric Light in Belgium.—With a desire to further encourage the use of electricity by private persons, the Communal Council of Brussels has decided to reduce the tariff. A kilowatt-hour is, in future, to cost 70 centimes instead of 80 centimes; further, when every lamp used by a subscriber is kept running for an average of 1,000 hours per year the price will be reduced 5 per cent., and the reduction will continue in proportion to the consumption until a price of 60 centimes per kilowatt-hour is reached. The tariff for illuminated advertisements and signs, and or outdoor lighting, is to be 50 centimes per kilowatt-hour. In the course of the second year of working the city hopes to have completed two secondary stations in the upper part of the city, as well as the laying of mains in the Quartier Léopold and the Quartier Louise. The expenditure involved will ultimately amount to about 3½ million francs, and an increase in the private consumption is counted upon to insure a financial success.

Electric Carriage.—It is announced that a carriage propelled by electricity, such as those which some time ago made the journey between Bordeaux and Paris, will shortly make a long run of over 1,000 miles in Italy. It is the property of Cavalier Giuseppe Ricorde, who will conduct it himself. Starting from Milan it will go *vid* Brescia, Piacenza, Parma, Reggio, Modena,. Bologna, Florence, Rome, Naples, Civita Vecchia, Leghorn, Spezia, Genoa, Savona, Turin, and Milan. The carriage contains four seats, and can proceed at the rate of from seven to ten miles an hour. Signor Ricorde is a well-known sportsman, and is said to be always ready to encourage any new invention. By the way, the Paris publication *Le Vélo* states that some of the French competitors in the late horseless contests will visit Tunbridge Wells on the day of Sir David Salomon's experiments in the stock show meadows. Considerable interest is being taken in horseless carriages in America at the present time through the Chicago *Times-Herald* prize contest for horseless carriages to run from Milwaukee, Wis., to Chicago, on November 2 next.

Obituary.—Kommerzienrath Joh. Sigmund Schuckert, who died on 17th ult. at Wiesbaden, at the age of 49, after a long illness, was a remarkable figure in German electrical science and electrical industry. Born at Nuremberg (in 1846), after receiving instruction in his native town, young Schuckert spent five years in various works in Stuttgart, Hanover, Hamburg, and Berlin, whence he proceeded to America, where he was employed at New York, Baltimore, Cincinnati, and Newark. In 1873, upon his return to Germany, he started a small works in Nuremberg, and constructed his first flat-ring machines, a type which, in France, has been exploited by M. Fabius Henrion, who was long his representative in that country. A large number of electric central stations were erected by the firm which Herr Schuckert founded, and which, since 1893, has been known as the Elektricitäts-Actiengesellschaft vorm. Schuckert und Co. A tolerably prolific inventor, his name will especially be associated with the Pilsen arc lamp and the celebrated parabolic projectors, regarding whose merits and those of the production of a rival French firm a discussion between the principal parties interested was recently waged in these columns. The premature death of such a man is eminently to be regretted.

Coming to England.—We read the following in a Transatlantic contemporary: "H. B. Cox, of Hartford, Conn., the inventor of a means of converting heat into electricity, is leaving to take up his permanent residence in England, where capital has been furnished him to engage in the manufacture of the apparatus designed to carry out his plans. The British Government has already given Mr. Cox orders for 10,000 of his machines for the telegraph service. Sub-companies will also be formed in France, Germany, Belgium, etc. A strange feature of Mr. Cox's experience in this country is the fact that though he had 100,000dol. worth of *bonâ fide* orders from such companies as the Postal Telegraph Company, the Metropolitan and New York and New Jersey Telephone Companies, yet he could not raise 25,000dol. on them by which to carry on their manufacture. The electric light, as it burns in everyday use, converts electricity into heat. Mr. Cox says his invention is simply a reversal of this process. He says he converts heat directly into electricity, turning heat vibrations into elec-

Digitized by Google

tricity vibrations. The idea has been known since 1821. What he claims as his own is the making this practicable. He says the Commercial Cable Company, after putting it in daily use, declared that his machine did its work at one-eighth the present cost. The uses that the Cox machines are designed for are to light private houses, for ship lights, for lighthouses, for telegraph and telephone, for electric bells, for boat propulsion, and the general purposes of small motors. Lord Kelvin is cited by Mr. Cox as pronouncing this invention most remarkable, and just what is needed."

Mnemonic Rules in Electricity.—M. R. Busquet, writing on this subject in *L'Eclairage Electrique* of September 21, considers the simplest and most easily remembered rule to be Maxwell's analogy of a corkscrew—*i.e.*, if the corkscrew is advancing in the same direction as the current, the direction of the lines of force produced is the same as the direction of the corkscrew's rotation and reciprocally. Since the magnetic needle sets itself along the lines of force, this includes Oersted's rule. In the case of induction M. Busquet also rejects Faraday and Fleming's rules in favour of Maxwell's: that in a closed circuit, when the lines of force decrease, the direction of the current is the same as the rotation of a corkscrew, screwing into the circuit along the lines of force, and contrary when the lines of force are increasing. M. Busquet, however, thinks the rule might be made more complete by imagining the cork as well as the corkscrew to be movable, or by the analogy of the small hand-drills rotated by a screw and collar which are used for drilling thin pieces of wood or iron. Representing the increase and decrease of the lines of force as produced by the approach or withdrawal of the north pole of a magnet along the axis of the circuit, then if the advance of the screw shaft corresponds to the introduction of additional lines of force, the current will be counter-clock-wise, and will correspond to the direction in which the collar will rotate if the screw shaft is not allowed to turn. Reciprocally withdrawing the screw corresponds to taking out the lines of force, and gives a rotation to the collar in the same direction as the hands of a clock, which would be the direction of the current. M. Busquet further shows that the analogy of the screw and collar can be applied to a conductor moving in a magnetic field, and also to determine the field produced by a current in a rectilinear conductor, the collar being always considered movable when induction is dealt with.

Train Electric Lighting in Ireland.—An important development in train electric lighting was tested the other day on the Great Northern of Ireland Railway, the run being between Amiens-street, Dublin, and Drogheda and back again. A good many electrical engineers accompanied the party, and among the company were the general manager of the Great Northern Company, Mr. Thomas Robertson, Mr. Thomas Wallace, superintendent of the line, and several of the officials. The train was one which had just been turned out of the company's workshops at Dundalk. The main features of the lighting system are that each vehicle is provided with its own generating plant, and is in all respects complete in itself, the revolution of the axle of the carriage driving the dynamo producing the electricity for lighting the train while in motion, and storing sufficient current in the accumulators to light the lamps when the train may be standing at stations. The entire plant consists of a dynamo, which feeds accumulators placed underneath each carriage. The dynamo commences work as soon as the carriage moves, and the accumulators automatically come into action immediately the train slackens speed or stops at stations. The system, of course, obviates the necessity for providing generating plant at terminal stations for charging purposes. The train was electrically equipped by Messrs. J. Stone and Co., engineers and electricians, of London, the system being the invention of Mr. Arthur Gill, manager of their electrical department. The Great Northern Railway Company have three systems of train electric lighting at present in operation on their lines. The first is lighting from accumulators underneath each carriage, these accumulators requiring to be charged daily at terminal stations. In the second system the electricity is produced by a dynamo driven off the axle of the guard's van. The generating plant is also placed in the guard's van, and the entire train is lighted therefrom. The third system is the one which has just been tried. During the run up from Drogheda, which was accomplished in less than three-quarters of an hour, the lamps are said to have burned brightly. It is intended to place four five-candle lamps in the first-class compartments, two eight-candle lamps in the second-class, and two five-candle lamps in the third-class compartments. The experimental run made was conceded to be highly satisfactory.

An Electric Brake.—A braking apparatus, the patent rights of which have been acquired by the General Electric Company, is operated by the current from the motors when they have been reversed and act as generators, as a result of the momentum of the car. The controller consists of three cylinders, a controlling cylinder for the motors when working as motors, a brake cylinder or controller for the motors when reversed and operating as generators, and a receiving cylinder or switch. These three cylinders are provided with separate handles and an interlocking mechanism which is designed to prevent improper manipulation. The interlocking mechanism is also so arranged that a different throw is permitted to the brake cylinder when the car is going in one direction from that allowed when it is moving in the opposite direction. Under ordinary circumstances it is unnecessary to arrange the brake so that it will work when the car is moving backwards, as the backing of cars is contrary to the rules of some tramways; but in cases where a car is run backwards for a few feet, as on a switch or turnout, it is sometimes necessary to stop abruptly. For making such emergency stops the brake is arranged so that where there are successively graduated effects in applying it when running forward, this part of the cylinder remains idle when the car is moving backwards and an auxiliary set of contacts come into play, which apply the full force of the brake at once. With either the series-parallel controller or the ordinary resistance switch, the contacts upon the braking switch cylinder co-operate with the controlling cylinder. These connecting contacts render possible an important economy in the car wiring, as a considerable length of wire can be saved in equipping the circuits of the apparatus. The controller is provided with two bolts, serving as an interlock between the reversing switch and the controller and between the brake switch and controller. Lugs secured to the controller case have openings which form guides for the interlocking bolts, and the shaft of the controlling switch is provided with two notched collars, with which the ends of the bolts register. The notches indicate the off position of the controlling switch, and it is only in this position that it is possible to operate with the brake or reversing switch.

Electrical Progress in Japan.—The use of water power for the generation of electric current for street railway and other purposes is receiving considerable attention in Japan at the present time, and several undertakings are now, a correspondent says, being developed with this object in view. There is already one such plant in operation, and it is working very successfully—the street railway in Kyoto.

Digitized by Google

The line is 12 miles in length, and is operated on the single-trolley system. It has given such excellent results that in other cities—including Tokio, Yokohama, and Osaka—permission is being sought for building lines on the same system. The authorities of Osaka and Tokio, however, hesitate about granting the permission desired on account of the possible damage to water-pipes, which are being now laid down. What makes it so much harder to push the single-trolley enterprise in Tokio are the efforts of another syndicate to introduce the double-trolley system. This syndicate represents a capital of 1,900,000dol., and proposes to build 84 miles of road. Upon the settlement of the question in Tokio the result of the agitation in other Japanese cities will much depend, and in all places everything is ready for active operations as soon as the matter is settled and the desired permission obtained. Eight mines in Japan are worked by electric power and lighted by electricity, all the generators, motors, and incandescent lamps being, the correspondent adds, manufactured in Japan—but this we doubt. Excepting a special form of telephone, and the agglomerate carbon for the Leclanché battery, all the instruments and battery materials used in the Japanese telegraph and telephone services are also, it is stated, manufactured and supplied by native concerns. The following statistics concerning electric lighting in the three largest cities of Japan are interesting:

	Population.	No. incandescent lamps, 8 c.p.	Arc lamps, 1,200 c.p.
Tokio	1,303,876	 34,436	 160
Osaka.....	484,409	 22,203	 140
Kyoto	328,403	 12,638	 19

A preliminary survey has, moreover, been made by the Japanese authorities for the laying of a submarine cable to Formosa. Another correspondent writes that the municipal authorities of Tokio, in accordance with the recommendations of a committee of scientists and chiefs of municipal departments, have decided to avoid the electrolytic corrosion of the existing water-pipes and interference on the single-line telephone circuits by compelling the use of the double trolley over the projected 85 miles of roads in that city.

The Increased Voltage Question.—Mr. Sydney W. Baynes says that pressure of work makes it difficult for him to maintain a correspondence on the question of the increased pressure supplied at St. Pancras. He writes: "In reply to Dr. Fleming, I gather the gist of his remarks to be that very careful inspection and testing will be found necessary. This is an essential point in any well-regulated central station, and applies equally to a five-wire, high-tension alternating, or high-tension continuous-current system. I wish to make it clear that no sweeping change of voltage is contemplated. The consumers already supplied at 110 volts will continue to receive that voltage, and it is optional for them to change if they consider the lighting obtained from the higher voltage to be more satisfactory. I have had consumers owning two sets of premises, having 230-volt lamps in one and 115-volt in the other. After a fair trial of the two, they decided to replace the low-voltage lamps with the higher voltage. It seems strange that Messrs. Handcock and Dykes having "past experience with 220-volt installations" should have any difficulty in knowing where to procure lamps of that voltage. I regret I have not the pleasure of knowing these gentlemen, as it may be that, having an interest in the lamp-making industry, they feel somewhat aggrieved at not being ready to meet the demand; but the loss has no need to be of a permanent nature, as the field is open to all. As to their invitation to repeat my experiments through the medium of an expert, much as I should like to assist my friends in their thirst for knowledge, I am not at their service in this respect. I have had close on two years' labour in this direction. Let them study the matter for a similar period and then they will better understand the subject. What, for instance, do they mean by asking me to submit a 220-volt lamp to a total variation of 8 per cent., which is equivalent to a continual fluctuation of nearly 18 volts? No, I must decline with thanks, and suggest that when central-station engineers are allowed a latitude of 18 volts in the regulation they will conclude that the millennium is not far distant." Mr. Baynes remarks that this letter closes the correspondence as far as he is concerned. Messrs. Handcock and Dykes have since stated that they are not interested to the extent of a single penny in any electrical manufacture whatever.

The Physiology of Death by Electric Shock.—Mr. Henry McClure remarks on this much-discussed subject: "That strong arterial contraction and engorgement of the large veins and right side of the heart are present in death from electric shock cannot, I believe, be contested. The contraction of the arteries is unquestionably due to a physical cause, but I do not think with Dr. Shettle that this cause acts primarily on the contents of the vessels (blood being a conductor), but rather upon the badly conducting or insulating nerves and arterial centres. Faraday taught us long ago that the seat of the phenomena was not in the conductors, but in the insulating medium surrounding them. The electrical energy does not travel by the wire but by the insulating sheath or dielectric surrounding it; the function of the wire is to dissipate the energy crowding into it from the dielectric, which else would take up a state of strain and cease to transmit any more. The blood, fluids, and opaque tissues of the human body act as the conductors, or wires, and the transparent tissues as the dielectrics, and these transmit all the energy. This I have tried to explain elsewhere. The kinetic electricity in traversing such tissues becomes static, resulting in a strain of the medium; the shearing stress of the current has altered the condition of the molecules; there is no displacement of the molecules as a whole, as has been pointed out by Prof. Lodge, but of their constituent atoms, and the stress, if strong enough, may result in electrolytic disruption. There is tension along the lines on which electricity is travelling and pressure at right angles to this. This is just the force that would narrow the calibre of the artery; this atomic displacement is most probably propagated along the nerve in the same manner as in the causation of muscular contraction. It is a spring back force, and under normal conditions would stimulate at make and break of the current, but under the conditions we are considering the molecular structure has been so altered by death that there is no spring back possible, the arteries remaining permanently contracted." It is interesting in this connection to note the recent experience of the crew of a fishing-vessel, belonging to Queenstown, which was struck by lightning in Courtmacsherry Bay. According to the captain's report, the entire crew were disabled by the electric discharge, being insensible for several minutes and then for a considerable time blind and deaf. When the storm came on, and the lightning played, the iron tiller was taken out of the rudder and replaced by a wooden one. Almost at the same moment the vessel was struck by "what appeared to be several pieces of fiery metal," and the noise made is described as "awful." When the crew recovered their sight and hearing, they found that the mainsail had been burned, the gaff broken, the deck planks burst open, galvanised hooks and thimbles had melted like lead, and the forecastle funnel had been twisted out of shape.

TUNBRIDGE WELLS ELECTRICITY WORKS.

This fashionable watering-place and health resort, which is situated on the border line between Kent and Sussex, is noted for its beautiful surroundings, and for the medicinal properties of the mineral waters found in the neighbourhood. The town, which was incorporated in recent years,

SIR DAVID SALOMONS, J.P., MAYOR.

has increased rapidly in size and importance. It is very opportune that the electric lighting enterprise at Tunbridge Wells should be completed during the mayoralty of Sir David Salomons. The history of the movement shows somewhat slow progress in the first instance. In 1890 a provisional order was applied for by the Corporation to keep an outside competitor from gaining the monopoly. The order being obtained, the matter was allowed to rest till the three years allowed by the Board of Trade had nearly expired. In the interval, however, an attempt was made to get rid of the responsibility and to sell the right to some private firm or company. This fortunately proved futile, and finally, in August, 1892, the Corporation called in Mr. W. H. Preece to give them a report as to the best means of lighting the borough. He most strongly advised them to keep the enterprise in their own hands, and by examples from other towns showed that the cost to the ratepayers at first would be more than balanced by the advantages derived and the profit earned in years to come. Considering the scattered area which would need the light, Mr. Preece stated that the alternating current must be employed wherever the station was to be placed. Considering the various sites available, together with the high-pressure system, he selected the present site, in the Corporation yard, by the goods station. The total preliminary cost he recommended was £25,000. Unfortunately, the matter came up before the Council for decision at a time when a new water-supply question had arisen which appeared likely to cause a large expenditure. The electric lighting question was therefore postponed again, and when finally undertaken, only £13,000 out of the £25,000 was asked for. As a consequence the money borrowed was insufficient to provided for reasonable contingencies and any little extensions required to supply demands for light. Hence the outlay of the remaining £12,000 has already been sanctioned. Mr. Preece at first recommended that the charge per unit should be 8d., but this charge was reduced to 6d. per B.T.U. before the supply began. The demand for light has, in consequence, been much increased, and already the equivalents of some 4,000 lamps have been connected to the mains. During this year Sir David Salomons, as mayor, has given the electricity department his energetic support, and has done all in his power to popularise the new illuminant. As an example of his untiring effort, we give below the programme of the official inauguration, which is to take place on Wednesday next. The borough electrical engineer, Mr. H. L. P. Boot, was appointed early in July, and under his direction the work of connecting consumers, etc., has progressed rapidly. The following gentlemen at present form the Electric Lighting Committee: chairman, Councillor T. Ashby Wood; his Worship the Mayor (Sir David Salomons), Aldermen Pink, Robb, and Clifford, Councillors Howis, Tinné, and Finch.

THE PANTILES, TUNBRIDGE WELLS.

The following is the programme of proceedings at the opening of the municipal electricity works at Tunbridge Wells on Wednesday, October 9, 1895:

1 p.m.—The Mayor has kindly consented to provide refreshments in the Camden Hall at 1 p.m., where the

Digitized by Google

Council, officials, and guests will assemble. Mr. Councillor Ashby Wood (as chairman of the Lighting Committee) will then make a speech, to which the Mayor will reply, and will then call upon Mr. W. H. Preece for a few remarks. The health of, and a vote of thanks to, the Mayoress will be proposed and seconded, which Sir David will acknowledge.

2 p.m.—Carriages will be in waiting to convey the company to the electricity works; where the machinery will be running, and the Mayor, after a few remarks, will ask the Mayoress to switch on the electric light.

3 p.m.—On leaving the works a procession will be formed in the following order: four mounted constables, Sir David's petroleum carriage (to be drawn on a trolley supplied by Mr. Smith), police force, military band, workmen employed in laying the mains, steam fire brigade, manual engine, members of the cyclist club, Cygnus Club, harriers and gymnastic club, salvage corps, Press (in carriages), Rusthall Fire Brigade, tradesmen's association, officials of the Corporation, councillors, aldermen, fire brigade, Ceylon Band, Lighting Committee, the Mayor and Mayoress (escorted by the yeomanry), St. John's Ambulance, visitors, etc.

The procession will pass through the principal streets to the Town Hall, where the Mayor and Mayoress, accompanied by the Corporation, will visit the electrical exhibition. This exhibition will be open to the public on Monday, October 7, at 4 p.m., and close on Saturday, October 12, at 11 p.m. The exhibits will include all kinds of electrical lamps, fittings, and appliances, electric motors, engines, dynamos, cooking, heating, and domestic applications of electricity. The kinetescope and phonograph also will be on view. During the afternoon and evening of each day, selections of music will be given.

General Description of Works.

The site finally selected for the works is most conveniently arranged for coal and water supply. As will be seen from Fig. 1, the buildings adjoin the goods station of the South-Eastern Railway, so that all the coal required can be shot from the trucks on the siding directly into the bunkers. In the immediate vicinity are the old reservoirs

H. L. P. BOOT, A.M.I.C.E.I. A.I.E.E., M S.A., BOROUGH ELECTRICAL ENGINEER.

which used to supply drinking-water to the town. The quantity of water in them would be ample for condensing purposes, but the largest one is at present used as a swimming-bath, and hence is not available. Still, by sinking a well at the rear of the station a good supply of water

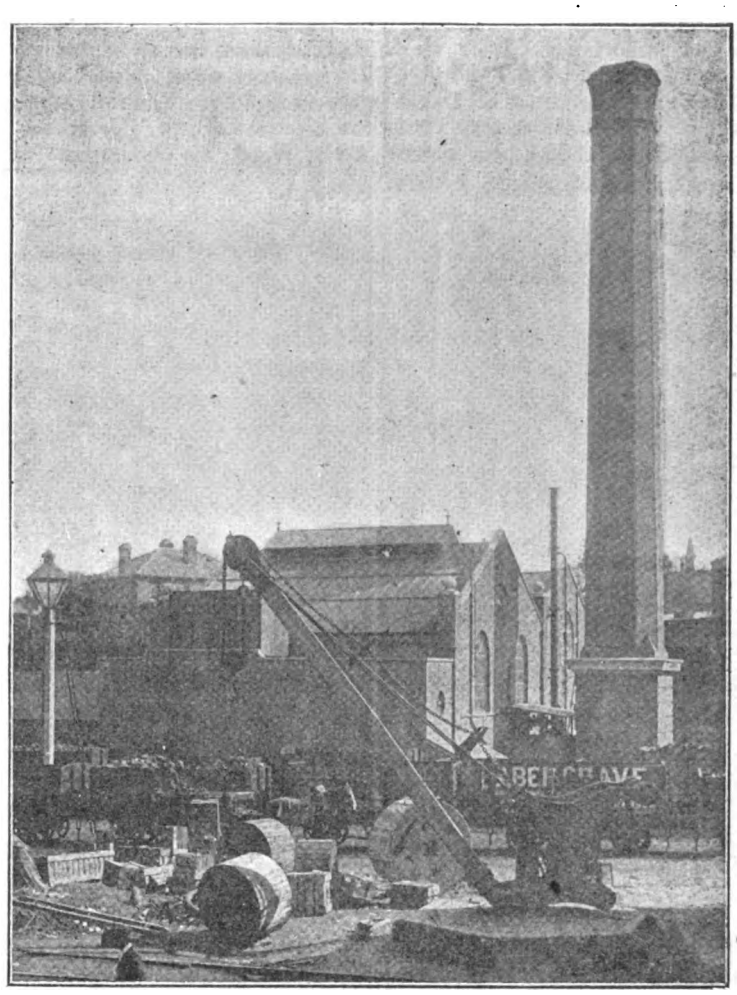

FIG. 1.—View of Station from Railway Embankment.

suitable for boiler-feed purposes has been obtained. The town supply is, however, laid on in case of emergency.

F.R.I.B.A., of Westminster. The general architecture will be seen from Fig. 2, which gives a perspective view of

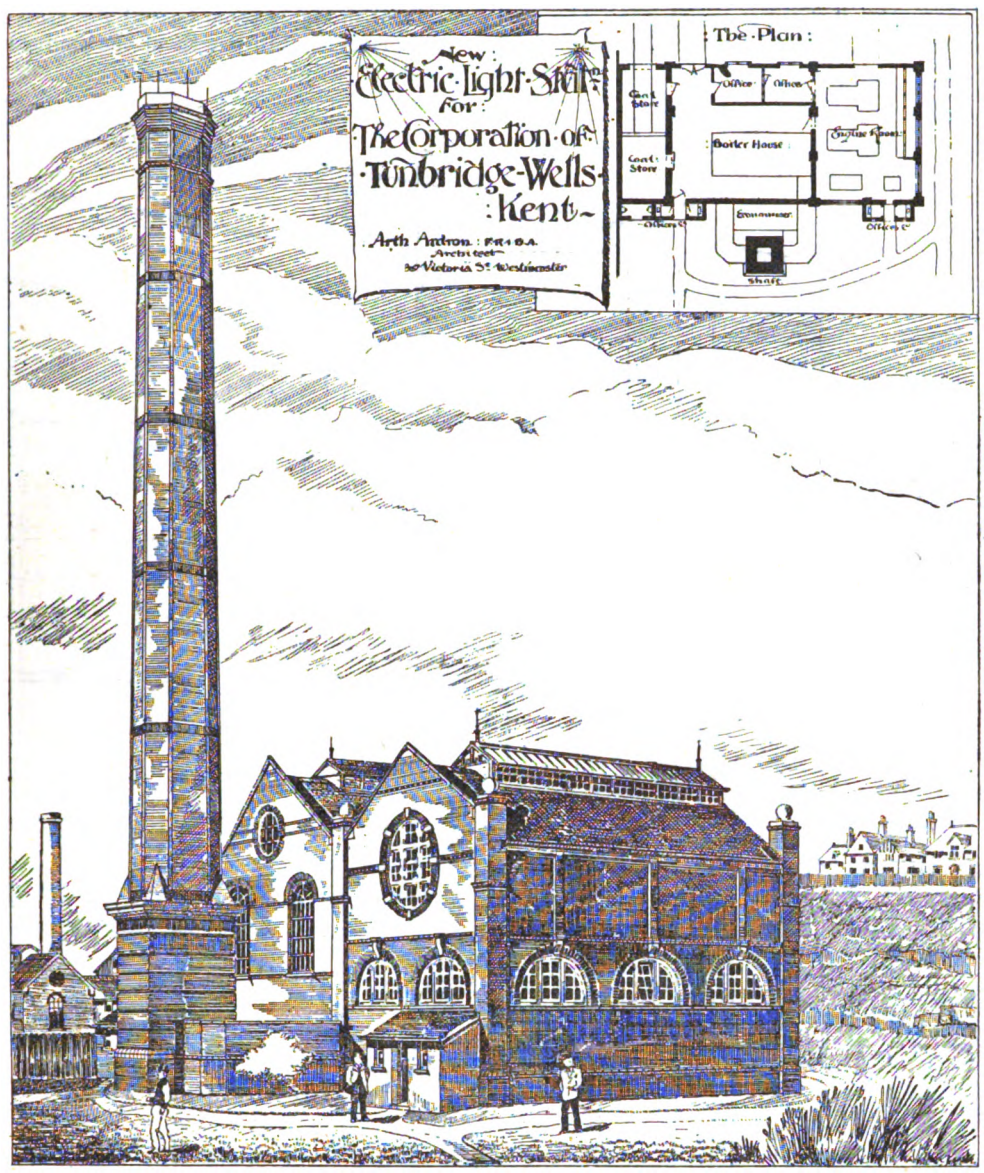

FIG. 2.—Elevation of the Tunbridge Wells Electricity Works.

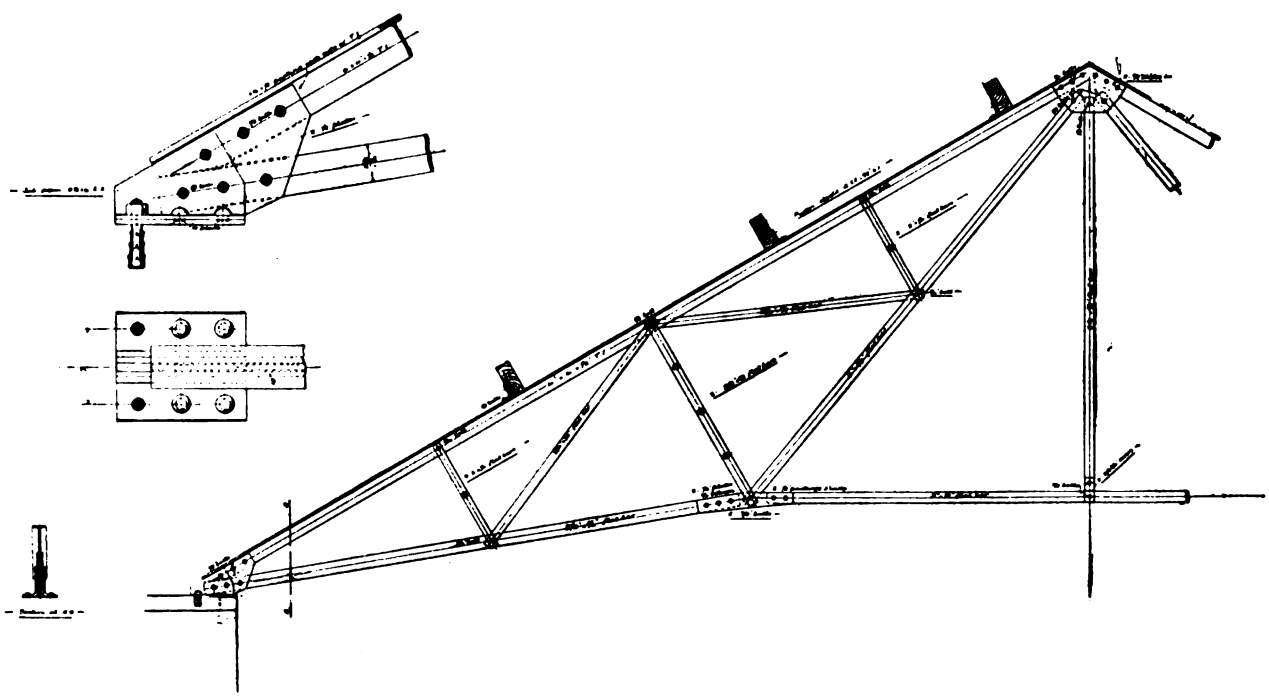

FIG. 3.—Details of Boiler-house Roof.

The buildings, which are arranged so that they can be conveniently extended, were designed by Mr. A. Ardon, the chimney and buildings. The interior is lined with white glazed bricks, with a coloured line about 4ft. from

Digitized by Google

the floor, which gives a pleasing effect. The details of the roof over the boiler-room are given in Fig. 3. The ground plan of the building, showing the machinery in position, is given in Fig. 4. From this it will be seen that the present plant consists of two 75-kilowatt alternators made by light mains. There are two of these rectifying sets—one for use and the other as a stand-by. The switchboard, supplied by Crompton and Co., is conveniently arranged at the side, with ample room behind for access. An overhead traveller runs the full length of the engine-room.

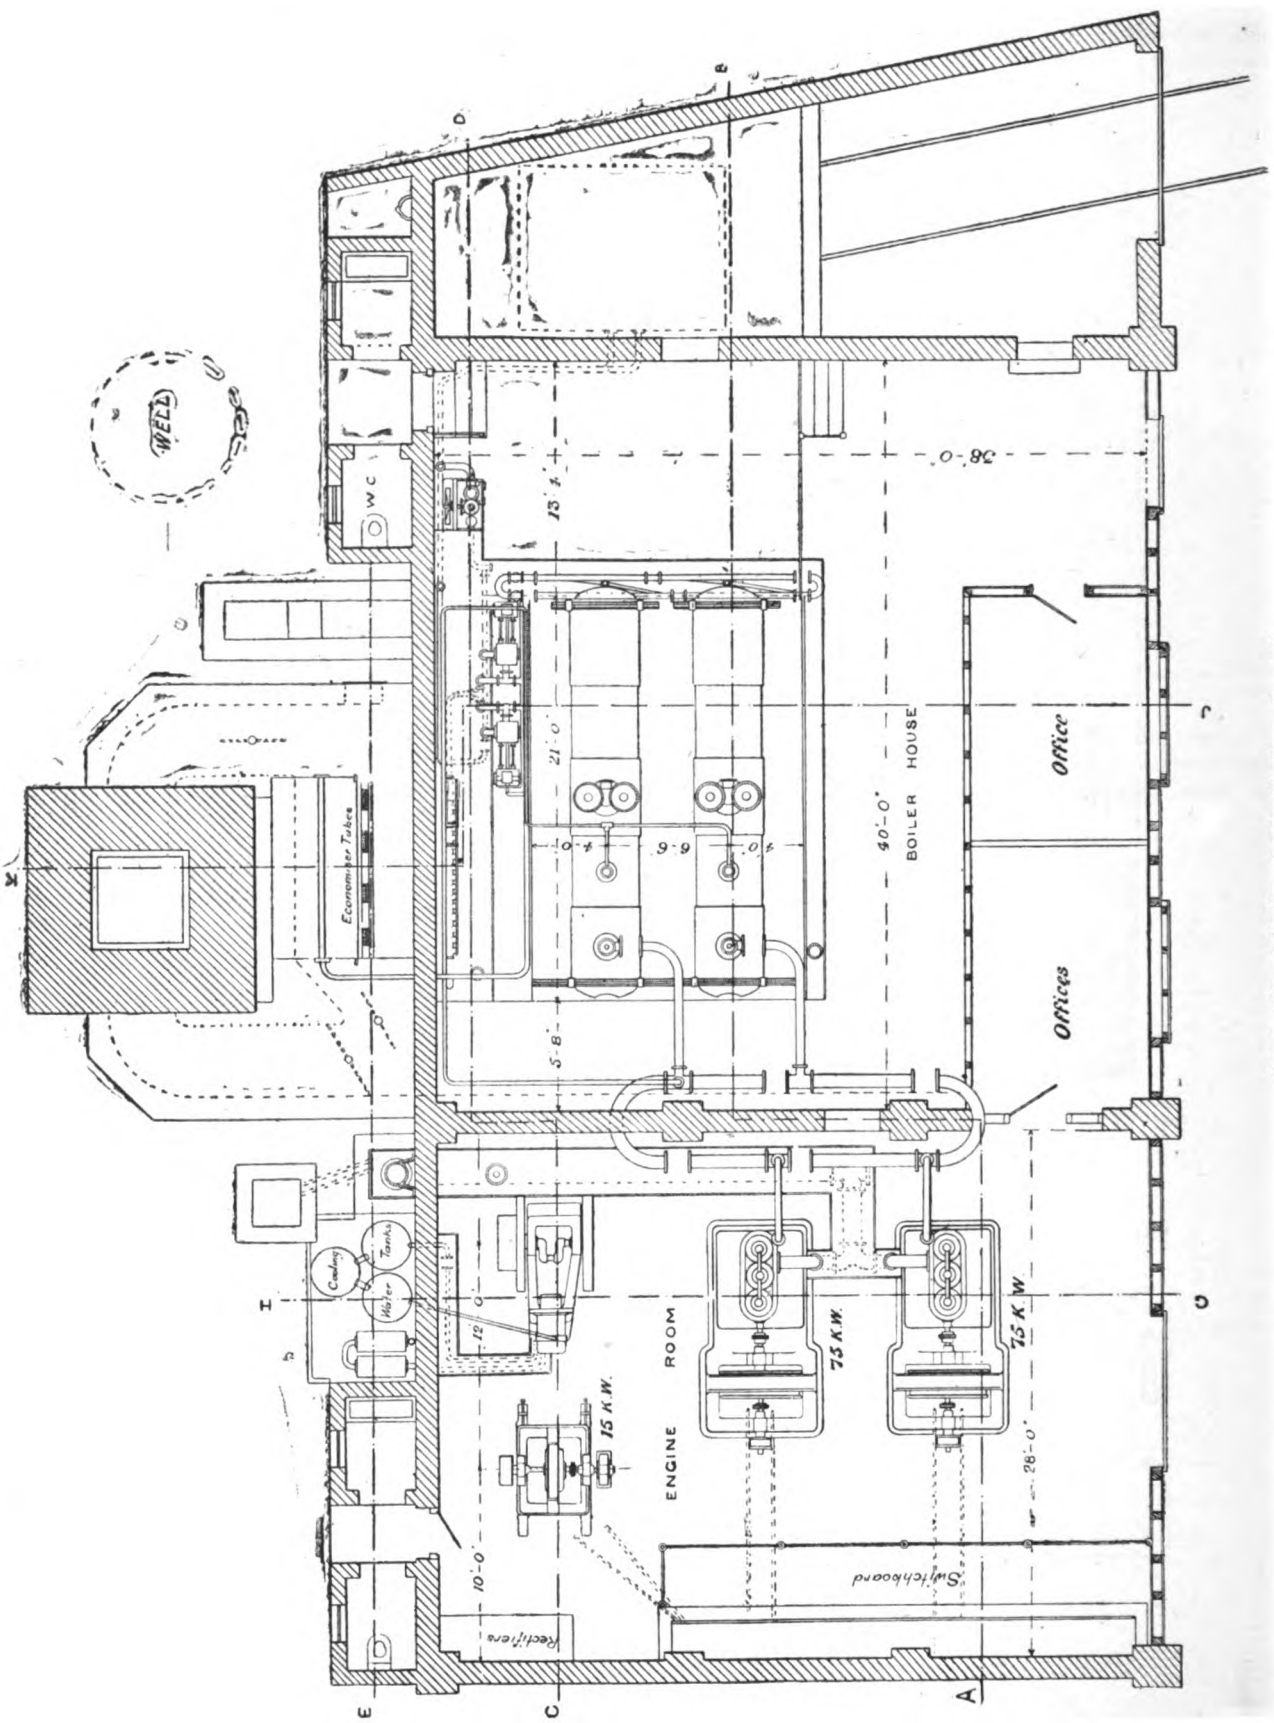

Fig. 4.—Plan of Station, showing Machinery in position.

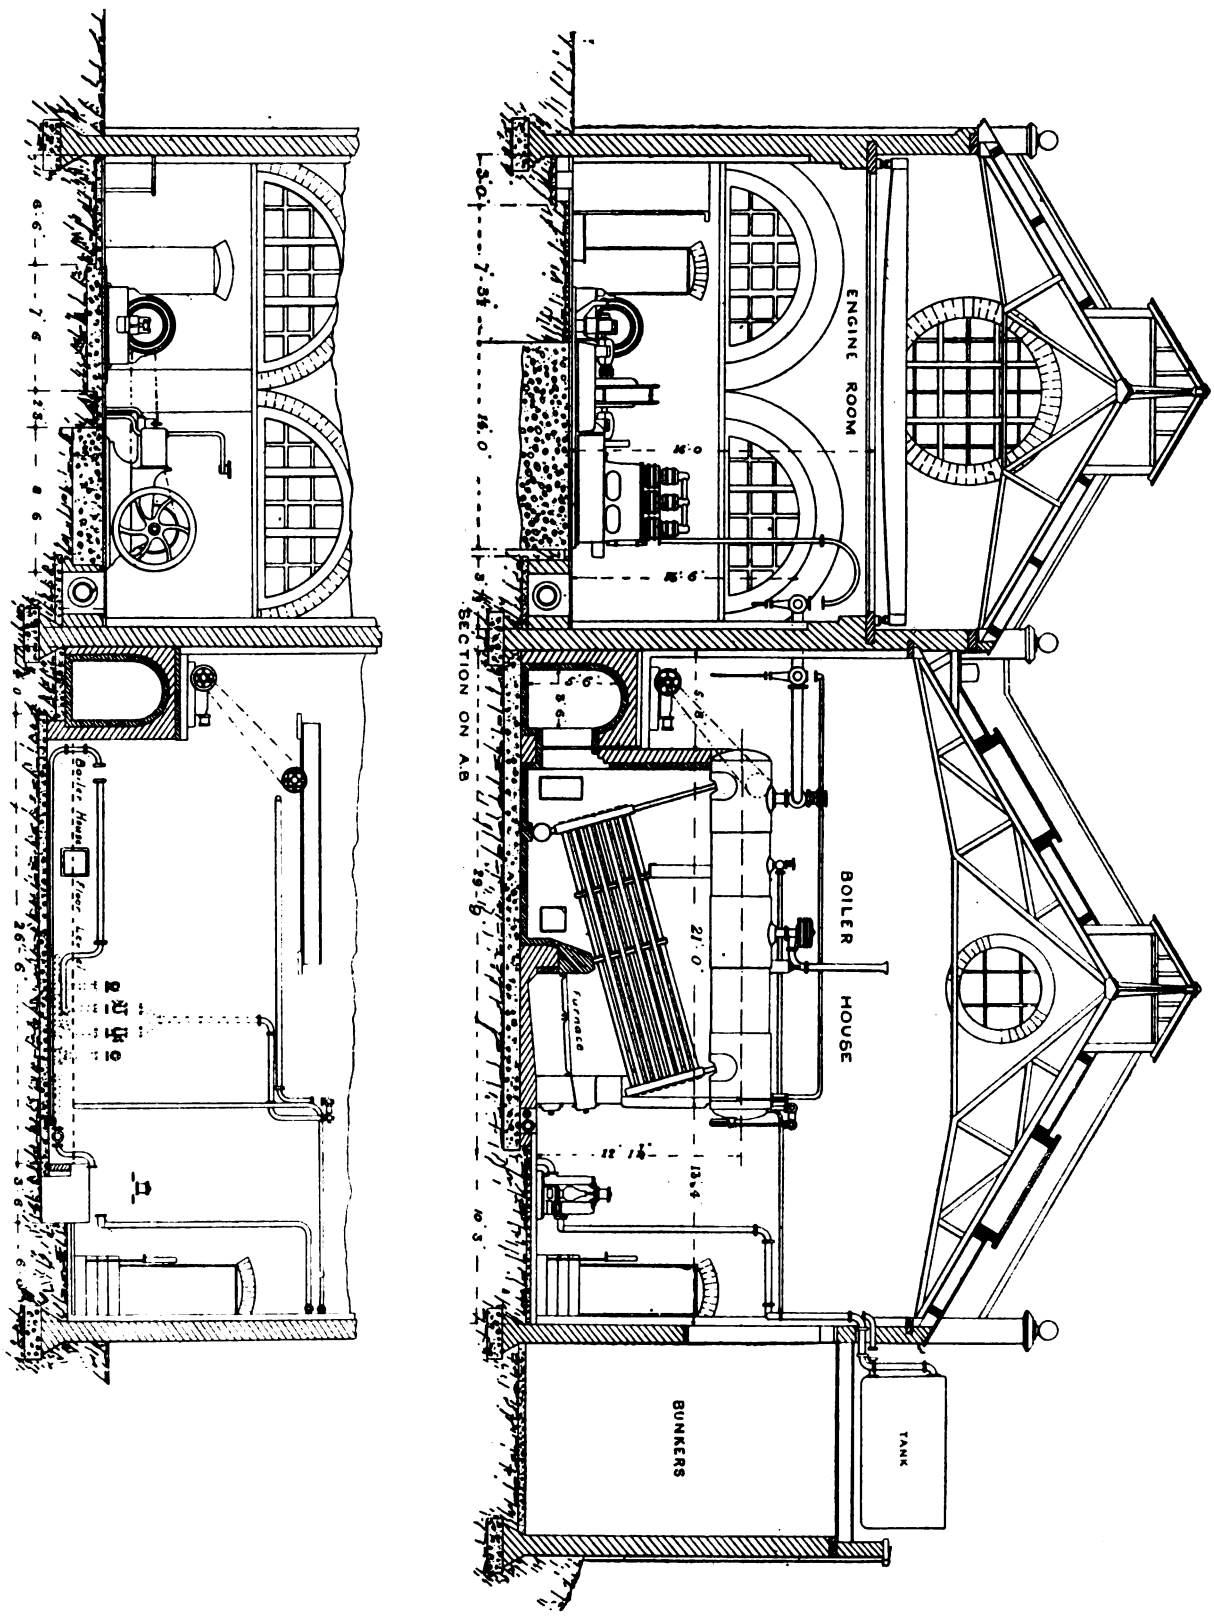
Messrs. Johnson and Phillips, coupled direct to two Willans engines, which take the evening loads. Besides these, a Stockport gas-engine of 15 nominal horse-power is provided and connected by link belting to a 15-kilowatt alternator as a daylight plant and to take the light loads. In the corner, beside this alternator, the two Ferranti rectifiers are placed, which are required to supply the arc

Steam Generating Plant.

The boiler contract was placed with Messrs. Babcock, Wilcox, and Co., who have installed two of their tubular boilers. Each of these has a heating surface of 1,426 square feet, and is composed of eight sections of tubes. Each section is nine tubes high, the tubes being 16ft. long and 4in. diameter. The steam and water drum is 42in. diameter.

Digitized by Google

The working pressure is 150lb. per square inch, and the boilers were tested to 250lb. per square inch after erection. Two dead-weight confined-flow safety-valves are fitted on each boiler, and are connected to an escape-pipe which goes outside the building. The boilers were constructed under the inspection of the National Boiler Insurance Company, of Manchester, and are fitted with isolating valves next to the main stop-valves, also with Probert and Bridges's low-water alarms.



FIGS. 5 AND 6.—Sectional Elevations of Station.

Messrs. Babcock, Wilcox, and Co. also supplied the Westinghouse feed-pumps and all the necessary parts of the duplicate feed-pipe service, which can be seen from Figs. 4, 5, and 6. The large tank placed over the coal-stores is made of boiler plate, and has a capacity of 5,000 gallons. This is used to store the feed water, which is pumped up from the well by the donkey pump placed in the corner of the boiler-house. The same firm supplied the Green's economiser, which contains 128 tubes, and is provided with a small engine, shafting, etc., for working the scraping gear. The arrangement of flues will be seen from Figs. 4 and 6A, and as the boilers for future extension will be placed where the temporary offices now are, the main flue can be conveniently lengthened.

Steam and Exhaust Pipes.

The work in connection with both the exhaust and steam pipes was carried out by Messrs. Willans and Robinson. The main steam-pipe is 6in. diameter, and is arranged on the ring system, so that any one defective joint or section will not interrupt the steam supply. The pipes are of wrought iron, with Willans patent flange connections. The bends, however, are made of copper. The whole system is supported on brackets, so that the expansion of the pipe shall not cause undue strains in it. The steam-pipe is thus

Digitized by Google

overhead, and the valves are not so accessible as might be desired. Hopkinson valves are used throughout the steam-

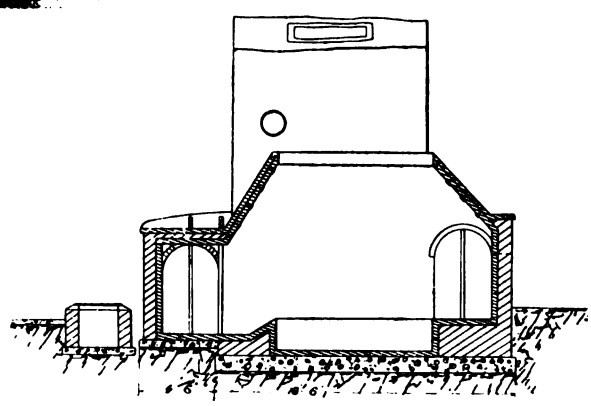


FIG. 6A.—Details of Flues and Chimney.

ring and on the connections. The exhaust-pipes are laid underground in trenches left round the foundations of the engines. The main exhaust-pipe is of 12in. diameter, and is made of cast iron. The connections from the two engines are 5in. diameter. Peet's valves, 12in. and 5in. diameter, are used in the exhaust system. At present no condensing arrangements are provided, and the exhaust steam is discharged into the atmosphere.

THE ENGINES.

These have been supplied by Messrs. Willans and Robinson, of Thames Ditton, and are of their noted high-speed central-valve type. They are of the GGG S size, compound, and run at a speed of 450 revolutions per minute. Each engine has three cranks placed at angles of 120deg. The low-pressure cylinders are 14in. in diameter, and the high-pressure 10in. The stroke is 6in. The engines are normally to give 110 b.h.p. to 115 b.h.p., but they are capable of doing about 135 b.h.p. at a push at the normal steam pressure of 150lb. above the atmosphere. A general view of these engines coupled to the alternator is shown in Fig. 7.

THE ALTERNATOR AND EXCITERS.

The alternators are of the Johnson and Phillips new type, having revolving field magnets and stationary armatures. The field magnets consist of two similar steel castings mounted on the spindle. Each casting has a series of nine poles projecting inwards, so that when the two are bolted together a series of 18 alternate poles is obtained. The excitation is provided by a single coil placed on the inner cylindrical part of these castings. The elevation of this machine attached to the Willans engine is shown in Figs. 8 and 9, but the details of construction can better be seen from

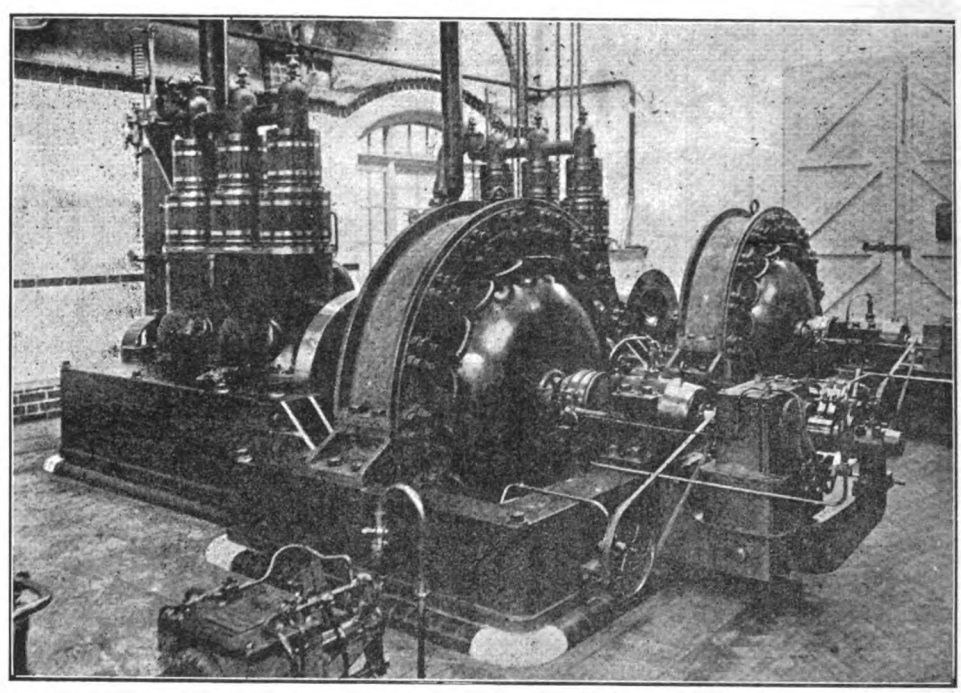

FIG. 7.—View of the Two 75-K.W. Steam Alternators.

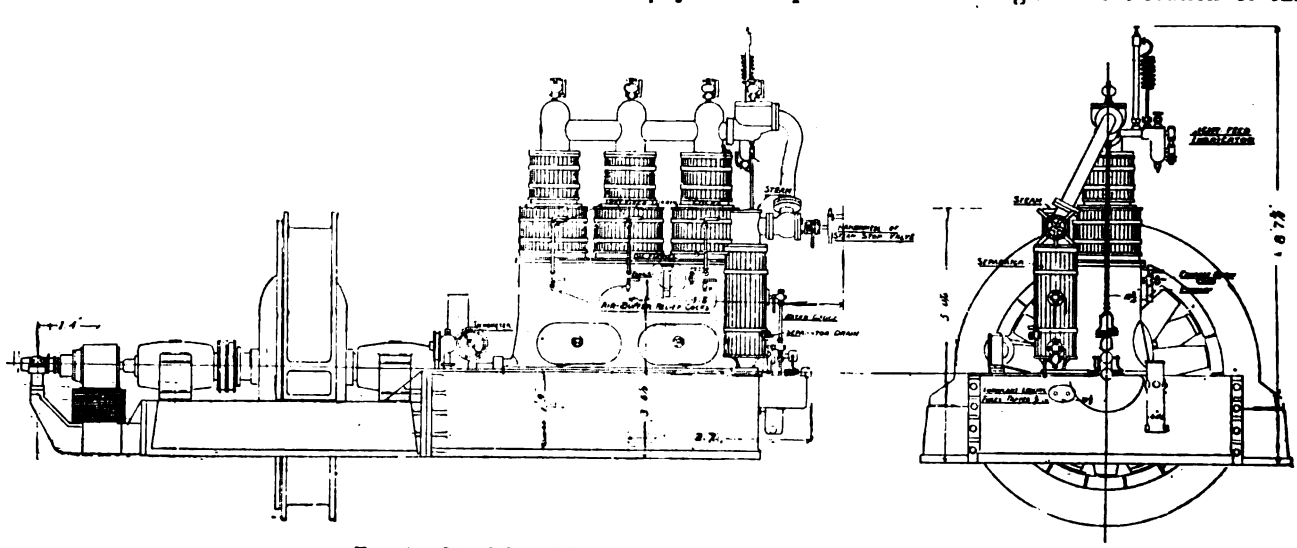

FIGS. 8 and 9.—Side and End Elevation of 75-K.W. Steam Alternator.

Digitized by Google

the general view, Fig. 10. The armature frame consists of a cast-iron ring, to which are bolted the segments. The coil round each segment is wound on a frame of the correct shape, and carefully insulated. Then the thin iron plates forming the core are inserted one by one until the required section is obtained. They are then clamped by bolts passing through the end plates (seen in the perspective view). A complete and readily interchangeable segment is thus obtained, which can be bolted in position on the frame in a very short time. The complete envelope of insulation round the armature wires gives a very high insulation resistance. The exciters are placed on the prolongation of the armature shaft, as shown in Fig. 10, and the field magnets of these shunt exciters are supported on a bracket bolted to the bedplate. A continuous flow of oil through the bearings is automatically provided by means of a small circulating pump driven by a belt from the shaft. There are at present in use two of these alternators, capable of giving 36 amperes at a pressure of 2,100 volts, the speed being 450 revolutions per minute, gives a frequency of

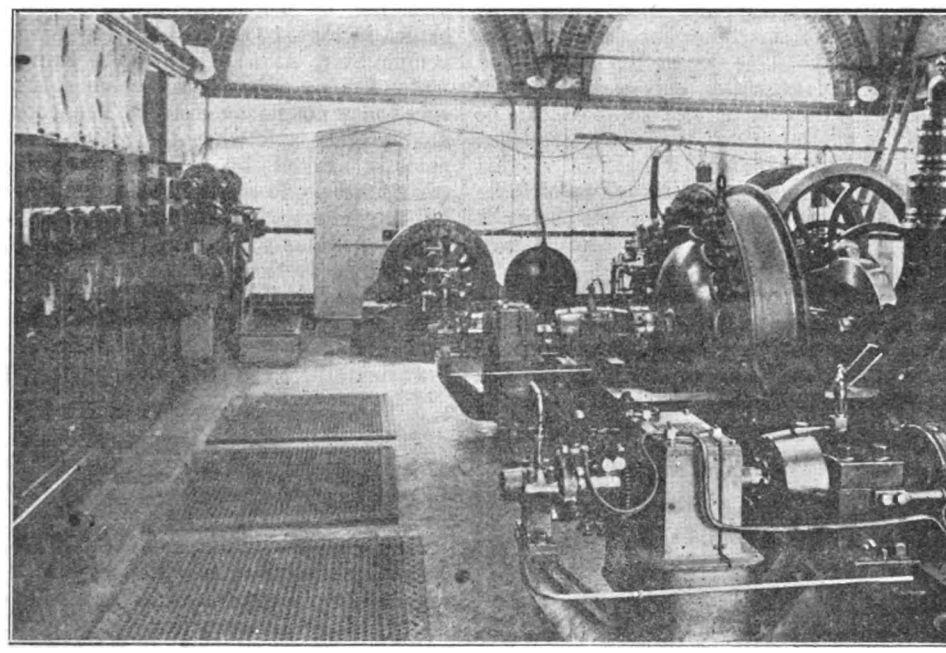

FIG. 10.—View of Engine-room.

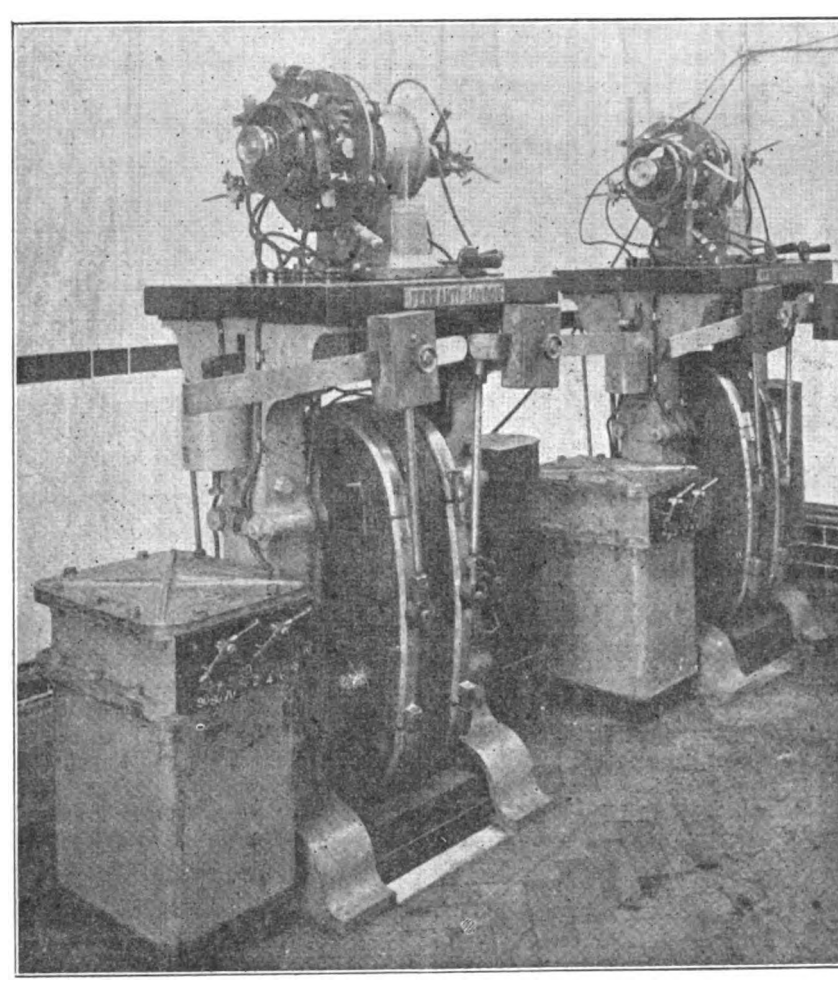

FIG. 11.—View of Rectifying Plant.

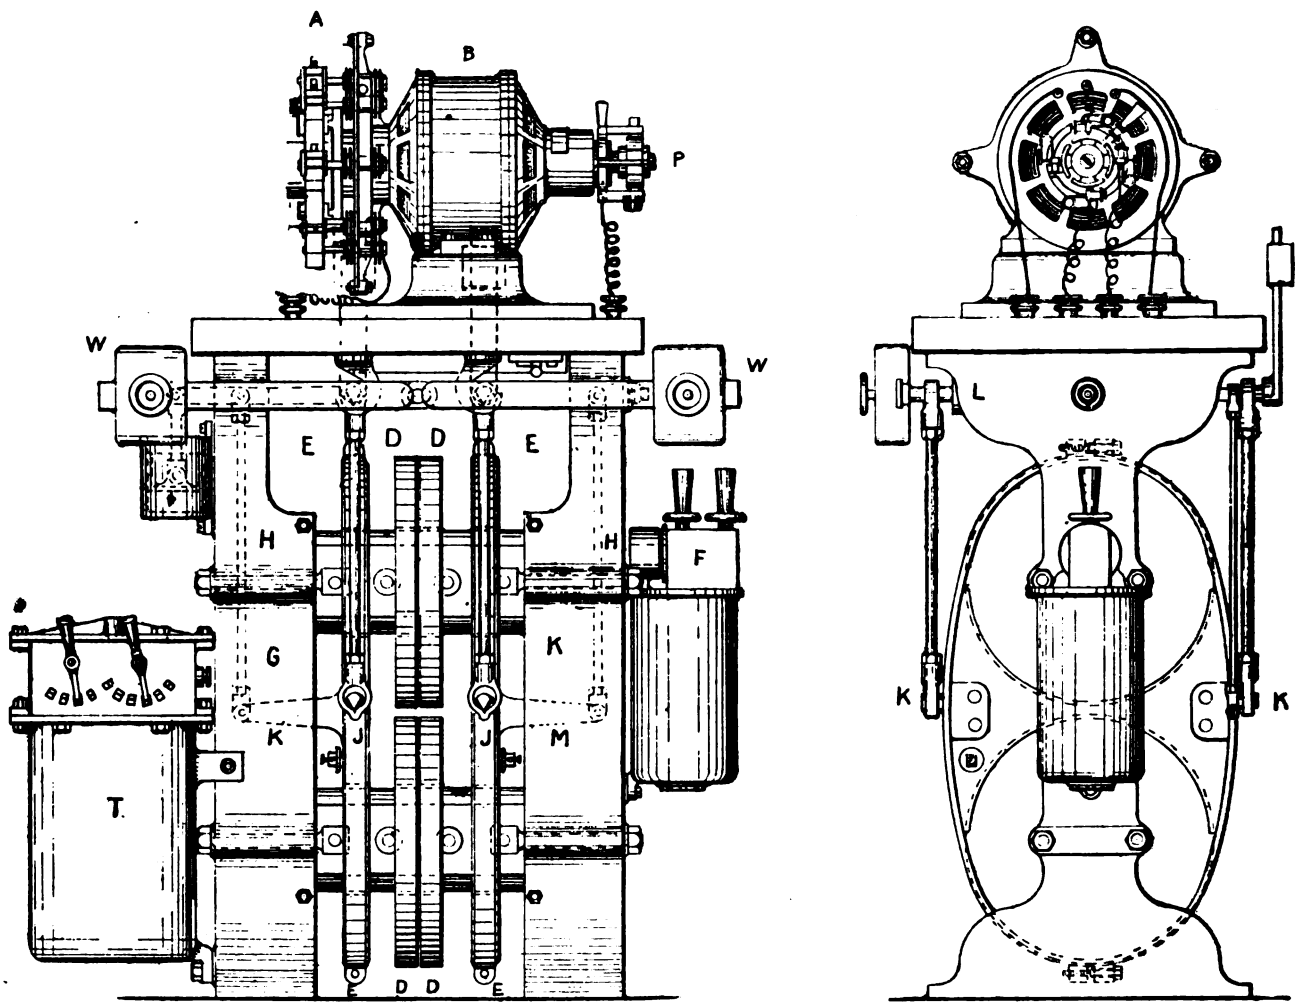
Digitized by Google

68. The smaller alternator is driven at 580 revolutions by the gas-engine, and is rated up to 15 kilowatts.

Ferranti Rectifiers.

The arc lighting system is supplied with current by the now well-known Ferranti machines for rectifying the alternating current required. This system has as its main advantage that one type of generator only is required in the station, and hence the number of sets supplied can be reduced. For instance, at Tunbridge Wells, were rectified currents not employed, arc dynamos would be needed to give the high-voltage continuous current. Two of these arc machines would be required at first, one being a stand-by. Then when the supply is given continuously throughout the night, as required by the Board of Trade, two engines would have to be running—one to supply the arc lights, and one alternator to supply the very small demand for private lighting. With the present arrangement one alternator will be able to supply both the arc and incandescent lighting at such times, and the two together will provide an economic load for the set. This shows a distinct advantage over running two sets at light loads, at which the engines do not give economic results. The rectifiers, however, at present require special attention, which somewhat raises the cost of supervision.



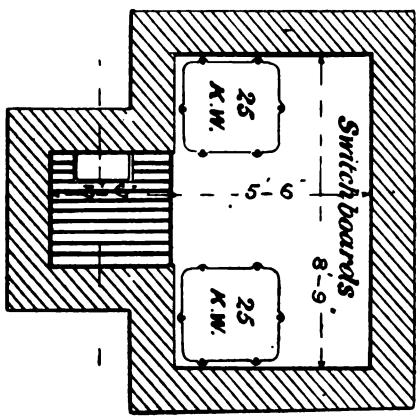
Figs. 12 and 13.—Details of Ferranti 25-light Rectifiers.

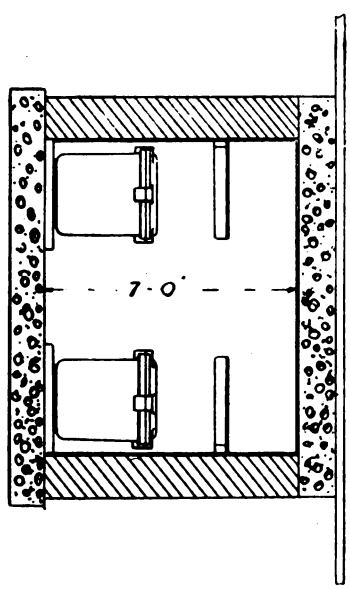
Fig. 11 shows the two 25-light rectifiers in use at Tunbridge Wells. The details will be seen from it, and from Figs. 12 and 13, which show two views of one of the sets. The main principle of the apparatus is simple, but various details required most careful attention to ensure a commercial apparatus. The first *sine qud non* is a truly synchronous motor to drive the commutator, and it is the failure of the motor to follow the variations in speed of badly-governed engines that has caused the majority of trouble found with these rectifying apparatuses. The next interesting feature is the regulating gear. Instead of rectifying at constant potential, and then regulating the arc lighting current by resistances to equalise any unevenness in the burning of the lamps, the regulation is effected by altering the voltage supplied to the commutator by means of a constant-current transformer. The contractors guaranteed that the variation of current when one lamp was extinguished in the circuit should not, at Tunbridge Wells, be more than ·06 of an ampere. The details of construction by which the above effects are obtained are shown in Figs. 12 and 13. The six-segment but two-part commutator, A, is driven by a Brown motor, B. This motor has six poles in its revolving part in order that the speed may not be excessive. The rotor is practically the field magnet, and when the motor is in synchronism this field is excited by a current rectified by the small commutator. In starting, this revolving part is energised by the alternating current, so that the speed rapidly rises to a value slightly above the speed of synchronism. The motor is then run as an ordinary shunt motor, a resistance being introduced into the field circuit. On attaining synchronism the resistance is cut out, and the field excited through its commutator from a few turns off the armature. The two-unit converter, T, is provided with connections to various windings, so that the motor can be supplied with any voltage from 60 to 100 to suit the conditions of the circuit. The main commutator, A, is overhung, and is built in two parts, each half carrying three segments. The parts in the commutator are varied with the periodicity employed, the number of segments increasing with the frequency, so that the time of commutation is approximately a constant for each design. The two halves of the commutator are securely interlocked on coned ebonite bushes mounted on a steel sleeve, so that the whole commutator can be removed from the motor spindle with the utmost ease. Separately insulated strips of copper are interposed in the air-gaps, between segments, for the purpose of mechanically breaking up the arc and thus preventing destructive sparking.

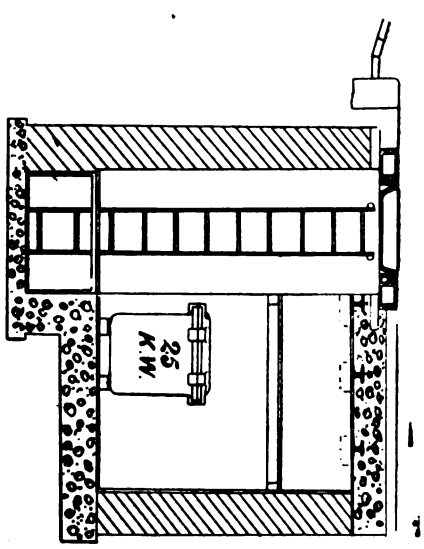
We now come to the constant-current converter. This apparatus consists of a closed-circuit iron core, C, with four fixed secondary coils, D D, and four swinging primary coils, E E. A water-break switch, F, is inserted in the primary circuit, and a dash-pot, G, is provided for steadying the motion of the primary coils. The constant-current

Digitized by Google

converter depends on the action of magnetic leakage on the transforming ratio of the transformer. The primary and secondary coils as arranged repel each other with a force varying with the strength of the current. The primary coils being free to move are thus repelled outwards against







FIGS. 23, 24, AND 25.—Details of Transformer Sub-Stations.

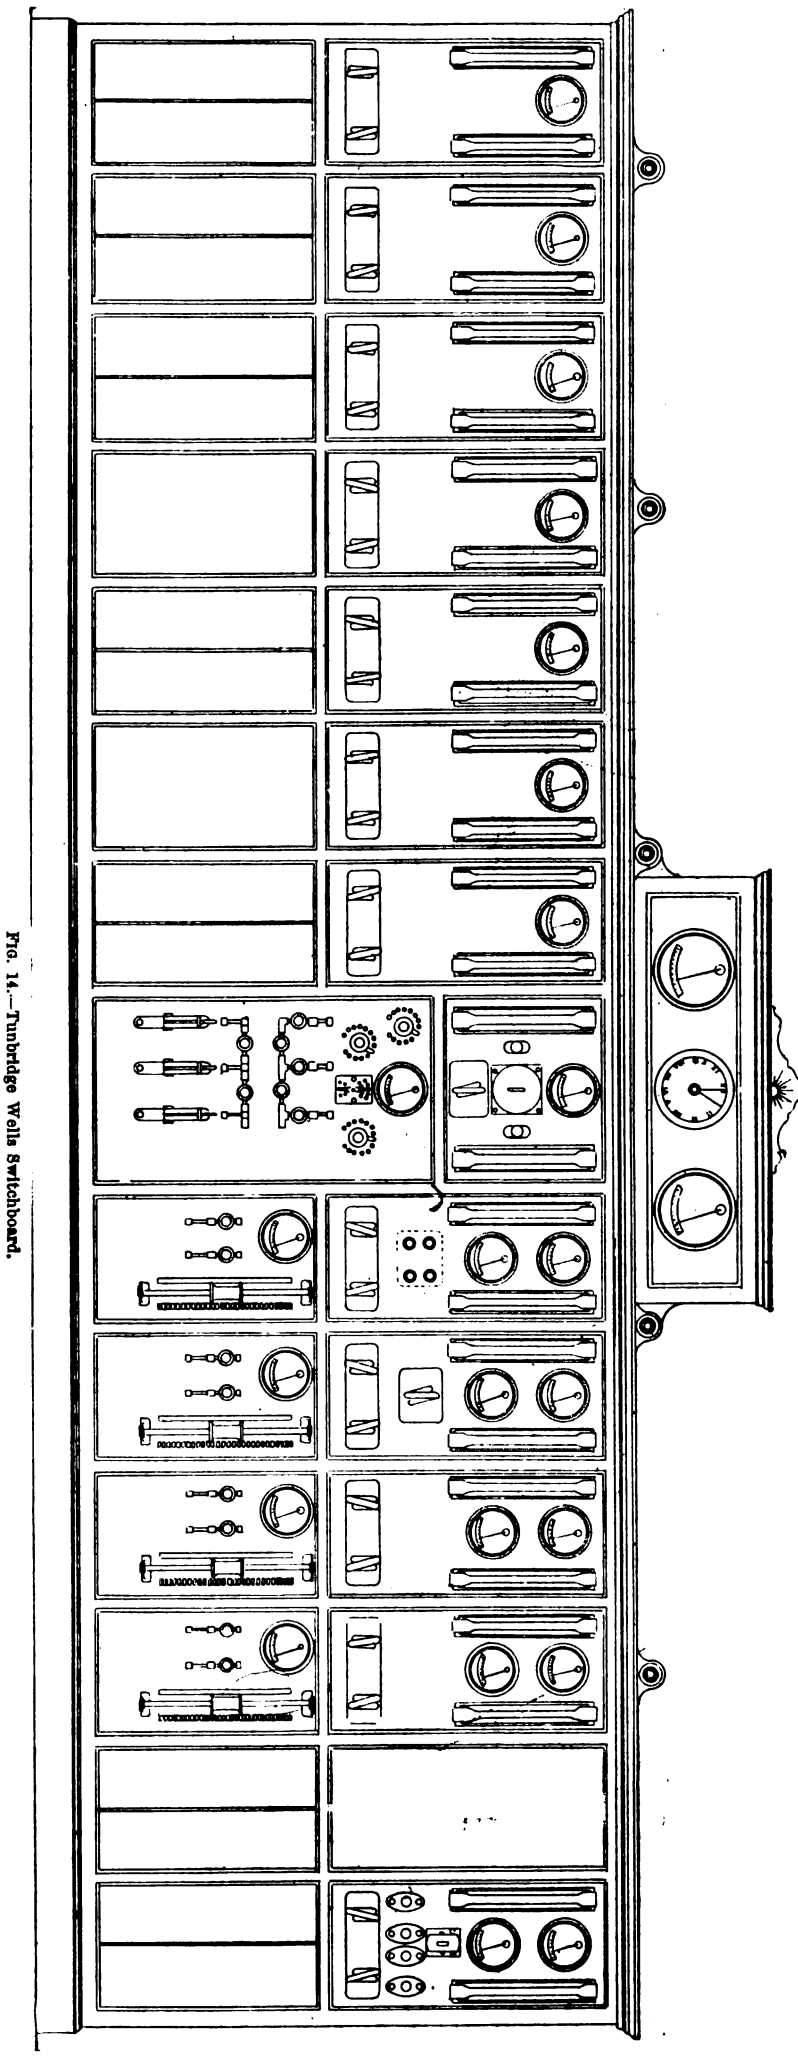


FIG. 14.—Tunbridge Wells Switchboard.

the restraining influence of the weights, W W. When these coils move further away the magnetic leakage increases, and hence the transforming ratio is reduced. The weights, being movable on the levers, can be adjusted to give any desired current for the normal position of the primary coils, and then a considerable alteration in the number of lamps burning can be made without altering the value of the current appreciably.

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscriber can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

MUNICIPAL ELECTRICAL ENGINEERS.

We really must protest against the attempt to impute personality to us—we have attempted to deal with a principle, not with a person. If it will serve any good purpose, we are willing to admit that Mr. Madgen is an ideal man for an organising secretary; that he is an ideal man in energetically pushing business. We have nothing to say against Mr. Madgen in any capacity except as secretary *pro tem.* to organise an association with many, if not most, of the members of which he has business relations. The statement of Mr. Wordingham, that municipal electrical engineers have not much time to spare, we fully endorse—but that is not the point. What we want to see is an association against which no objection can be raised from any quarter; and, as may be gathered from the course of events, we are, more or less, the mouthpiece of those who see objections, of those who are in a position to be members of an association and who desire to be members. It is not a pleasant duty to pull nuts out of the fire for other people, but it is a necessary one on occasions.

CORRESPONDENCE.

"One man's word is no man's word,
Justice needs that both be heard."

MUNICIPAL ELECTRICAL ENGINEERS.

Sir,—The committee who were appointed to draw up a scheme for the formation of a Municipal Electrical Association have read with much surprise your article in the *Electrical Engineer* of the 20th ult. Without commenting on the language which you have seen fit to use with regard to individuals, the committee think that it would be well to put you in possession of the facts relating to the matter, and they have desired me, as secretary to the first meeting that was held, to forward you a copy of the report of that meeting which I drew up at the time. From this you will perceive that the committee is composed exclusively of municipal electrical engineers, who, I think you will acknowledge, are free from any of the objections which you have enumerated in your article. It is a fact—although from the depreciatory manner in which you refer to them it may be a matter of surprise to you—that municipal electrical engineers are busy men, and have little time to devote to secretarial work: they therefore invited Mr. Madgen to undertake this work during the formation of the society. From the report, you will see that Mr. Madgen was only temporarily appointed, and the committee could obviously not appoint officers to a society which does not yet exist, their functions merely relating to the preparation of a draft constitution which is to be submitted to a meeting of municipal electrical engineers to be called later on. The officers of the society, when formed, will be elected according to the constitution approved at the meeting referred to.

No secrecy has been observed in the matter, a copy of the report which accompanies this having been forwarded to each engineer who was present at the meeting of July 8, 1895. All these engineers being duly accredited by their respective corporations to represent them at a discussion of the new Board of Trade rules, the committee was thoroughly representative in every way.—Yours, etc.,

C. H. Wordingham.

Manchester, October 2, 1895.

[Copy.]

Proposed Municipal Electrical Association.

At the meeting of the municipal electrical engineers to discuss the new Board of Trade rules held in Westminster on Monday, July 8, 1895, the subject of the formation of an association of municipal engineers was brought forward

Digitized by Google

by Mr. Rider, of Bolton, and was very warmly approved by the meeting. It was decided to appoint a working committee of five engineers to draw up the constitution of the proposed society, and to prepare a draft set of rules. The following gentlemen were elected by ballot: A. S. Baynes, A. B. Mountain, J. H. Rider, C. H. Wordingham, and A. Wright.

This committee held a meeting on the following day and appointed Mr. W. Madgen hon. secretary *pro tem.* Mr. Madgen having expressed his willingness to act, it was felt by the committee that his services would be of great value to them, he being thoroughly in touch with most of the central-station engineers in the kingdom, and having taken a very keen interest in the subject, being, in fact, the originator of the movement.

The main lines on which the association should be formed were practically settled, and a draft scheme will very shortly be prepared.

(Signed) C. H. WORDINGHAM,
Secretary of Meeting.

TELEPHONES AND THE BRITISH ASSOCIATION.

SIR,—The propriety of the contrast which I drew in my British Association paper between the telephonic conditions of Dorset and the Grand Duchy of Luxemburg has been challenged by one of your contemporaries—the *Electrical Review*—on the ground that, although Dorset is, as I stated, practically destitute of telephones, their absence is compensated for by the existence of a telegraphic network, which, from a map given by your contemporary, appears to comprise 73 stations, the suggestion being that Luxemburg is deficient in telegraphic, as distinguished from telephonic, facilities. The logic is somewhat of the horse-chesnut and chesnut-horse order, it being apparently assumed that because the telephone has been declared a telegraph by the Post Office the telegraph must necessarily be a telephone, and that the two inventions are interchangeable for practical purposes. This is a cherished illusion in some quarters, but is an illusion still.

But what are the facts regarding Luxemburg and Dorset? As I write I have before me the report for 1892-3 of the Minister of Posts and Telegraphs of the Grand Duchy. At page 2 the number of telegraph stations is stated to be 113. Now let me compare the facilities, both telegraphic and telephonic, respectively enjoyed by these two districts—equal in area and population.

Telegraph Alone.

Dorset: telegraph stations in 1895	73
Luxemburg: telegraph stations in 1893	113
Public telephone stations (used also as telegraph offices) in localities unprovided with exchanges, in 1894	26
	139

Balance in favour of Luxemburg, 66 telegraph stations. The total represents almost double the number possessed by Dorset. In addition, *all* the Luxemburg telephone exchanges are in connection with the telegraph system, and so may be counted as telegraph offices too.

Telegraph and Telephone Combined.

Dorset: telegraph stations in 1895	73
Telephone exchanges in 1895	3
	76
Luxemburg: telegraph stations in 1893	113
Telephone exchanges in 1894	59
Public telephone stations, as above	26
	198

Balance in favour of Luxemburg, 122. That is to say, the Luxemburg *excess* is almost double the Dorsetshire total. Another point:

Telegraph offices in Luxemburg open day and night	3
,, ,, ,, Dorset ,, ,, ,, ,,	0

And yet we Britons are continually being told by our Post Office that we possess the best telegraph system in the world—so good, indeed, that telephones are almost superfluous!

The following additional contrast, suggested by the meeting place of the association, is of interest:

	Population.	Number of exchange telephones.	Number of persons to each exchange telephone.
Ipswich	61,000	150	407
Helsingfors	65,000	2,150	30

The *Electrical Review* also deplores the fact that I confined my comparisons to Europe, and did not include the United States and New Zealand, both of which, it says, would have been entitled to rank in Group I., while their characteristics of management would not have lent colour to my deductions. The first assertion I admit; the second I traverse. To prove that two countries besides those I named are entitled to rank ahead of it, is a singular way of demonstrating the sufficiency of the telephone service of the United Kingdom. But no matter: that is simply an outcome of the *Review's* peculiar system of logic. I could not have gone outside Europe without including *all* extra-European countries, which was impracticable. Had I chosen two good examples, like New Zealand and the United States, the *Review* would probably have said: "Unfair and misleading! How about Kerguelen Land and Tristan d'Acunha?" Those who care to read the evidence given before the late Select Committee on the Telephone Service by the Postmaster-General of New Zealand, will perceive that at least two of the characteristics of management in that colony are quite opposed to those in force at home, while they coincide with the conditions which prevail in the countries composing my Group I.: (1) Low rates—*i.e.*, £5 per annum. Question 4,064: (2) Good country intercourse. Question 4,058: "We are a very scattered community in New Zealand, and there is a great number of places outside those exchanges I have named where there are telephone exchanges not included in these lists at all. There are scores of small places. Practically, our telephone service in the smaller parts of the country we look upon as auxiliary to the telegraph service."

As regards the United States, the rates have hitherto been high in most cases, and there has not been much competition, but there has been (1) local management in each town by a company dependent on its exertions for a livelihood, and (2) good country intercourse; so that two of my requirements are again fulfilled.

In its character of apologist-in-chief for high rates, monopoly, and inefficiency, the *Review* makes one or two other assertions which may possibly mislead the uninstructed, but which consideration for your space compels me to leave unanswered.—Yours, etc., A. R. BENNETT.

22, St. Alban's-road, Harlesden, N.W.

ELECTRIC TRACTION.

SIR,—I notice a misprint in the table belonging to Mr. Dawson's paper on page 371 of your last issue which is perhaps worth correction, inasmuch as the "car density per mile of track" is sometimes used as a more or less incomplete criterion of respective tramway systems. The Rouen lines have a total length of 25 miles, not 20; and there will be 50 motor cars, instead of 10. The horse-power available at first will be 750, not 900—there being three sets of belt-connected generators each of 175-kilowatt capacity. I think the figures relating to motor cars at Rouen and Pessac must have got interchanged in the table, as I can hardly imagine a line 3½ miles long with *50* motor cars and *300* h.p. only in the power-house. The mistake is not to be wondered at altogether: British Association papers are generally as full of misprints as an egg is full of meat.—Yours, etc., FRANK B. LEA.

Rouen, September 25, 1895.

Shunt Motors with Variable Speed.—Herr F. A. Wessel describes in the *Elektrotechnische Zeitschrift* of September 26 an arrangement which, he says, very simply and very efficiently enables electromotors to be run at variable speeds. The apparatus consists of a shunt motor with two collectors, which is connected with the Wessel-Egger reversing apparatus. The latter has hitherto only been used with constant speeds, but it has now been combined by the author with a regulating apparatus, which permits the revolutions of the motor to be varied as much as fourfold, and the rotary direction to be reversed.

TUNBRIDGE WELLS ELECTRICITY WORKS.

(Continued from page 393.)

The secondary pressure before reaching the commutator is thus kept proportional to the number of lamps in circuit. The four primary coils are coupled together in pairs, being held in position by teak coil carriers supported by split German-silver bands, J J. The coils are swung on knife-edges, K K, from cross-bars, L L, which also rest on knife-edged seats, M M, suspended from the slate base. The links, H, and arms, M, keep the coils vertical by giving a parallel motion. The secondary coils are firmly fixed on the core. Great attention is paid to the insulation of both primary and secondary.

Each rectifier is provided with pole indicator, quick-break reversing switch, and interchangeable plugs for switching either rectifier on to circuit. The arc lamps fed by these rectifiers are of the Brockie-Pell type, and were supplied by Messrs. Johnson and Phillips. The lamp-posts were cast by Messrs. Macfarlane and Co., of Glasgow.

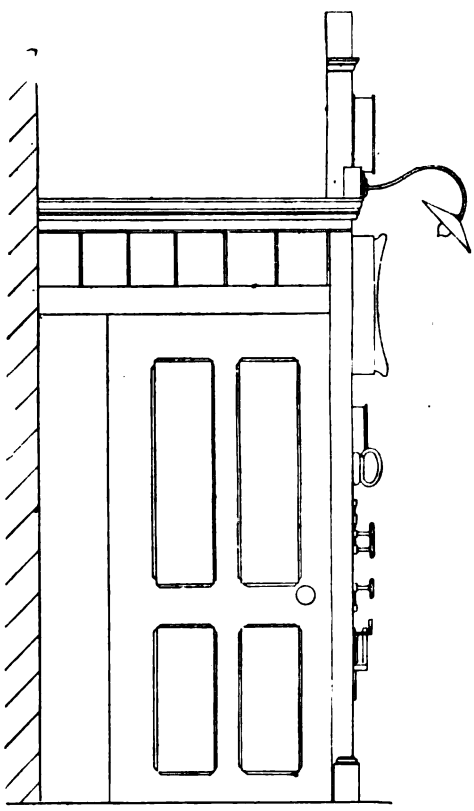

FIG. 15.—Side Elevation of Switchboard.

FIGS. 16 AND 16A.—Details of Plug Switch.

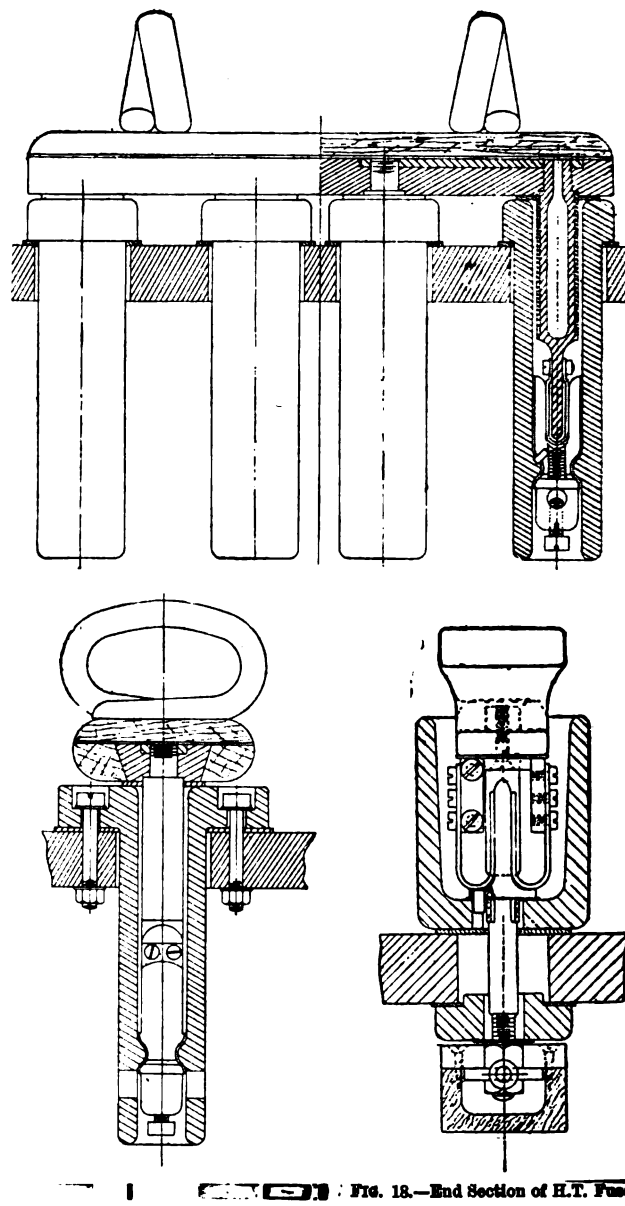

FIG. 18.—End Section of H.T. Fuse

one arc light circuit and two rectifiers. It is also designed for running the alternators in parallel, and is provided with the necessary synchronising gear. On the right-hand side of the switchboard are the three panels belonging to the alternators. Considering one of these panels only, the

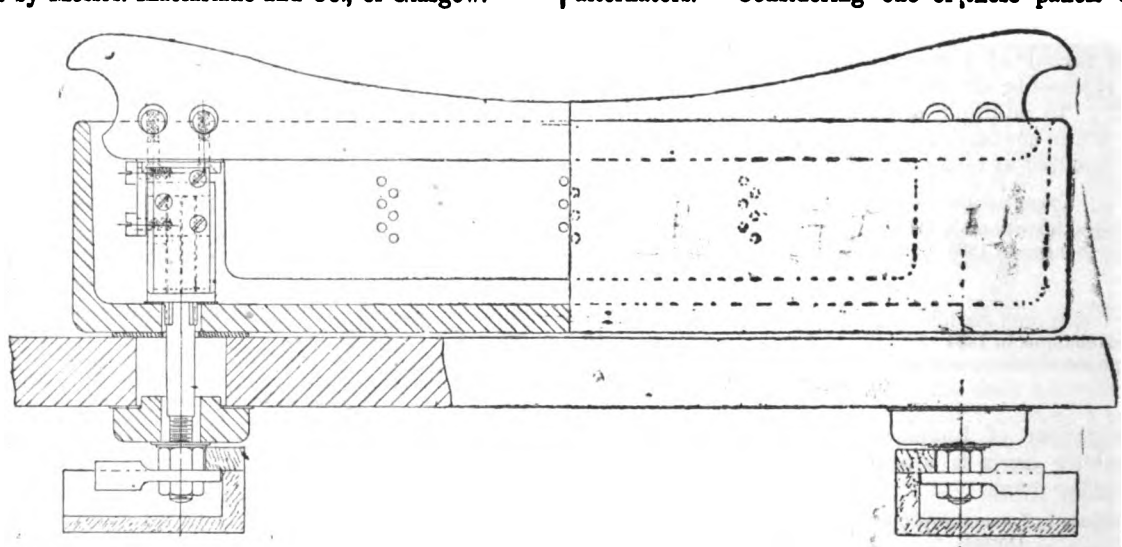

FIG. 17.—Elevation of High-Tension Fuse.

SWITCHBOARDS.

In this switchboard (Fig. 14 and 15), which was manufactured by Messrs. Crompton and Co., provision is made for three alternators and exciters and four main circuits; also for leads from the alternator are brought firstly to a pair of high-tension fuses mounted in stoneware, then through the ampere-meter to the high-tension double-pole four-break plug switch, also encased in stoneware. From these the

Digitized by Google

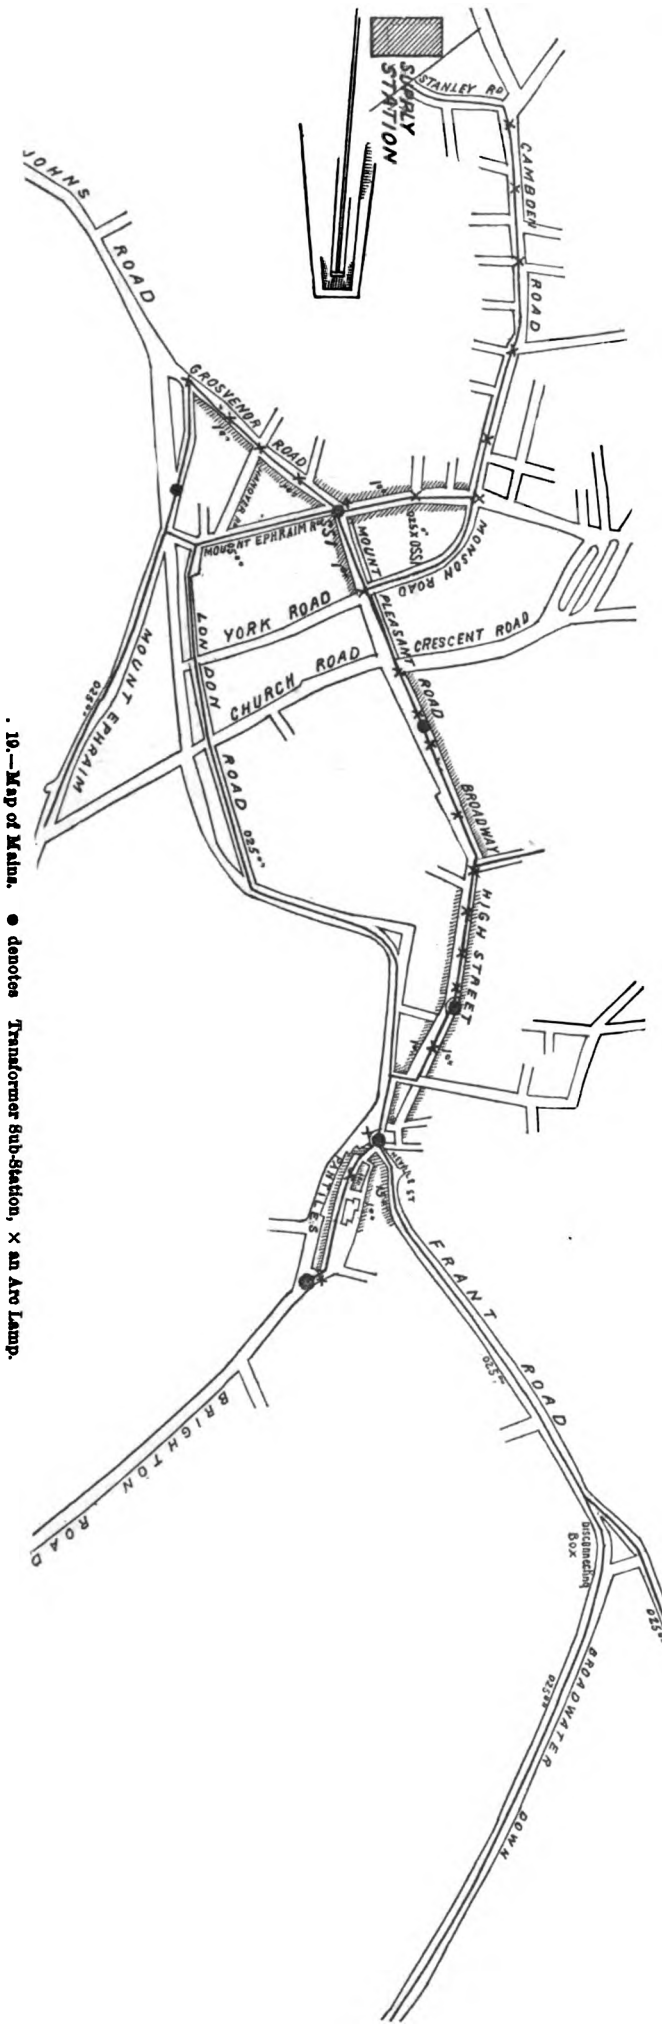

Fig. 19.—Map of Mains. ● denotes Transformer Sub-Station, × an Arc Lamp.

connections pass to the 'bus cables at the back of the board. Below the ampere-meter is placed the electrostatic voltmeter measuring the E.M.F. of the alternator without a reducing transformer. Below the panel containing the above apparatus is placed another containing an ampere-meter regulating switch and double-pole main switches and fuses in the exciting circuit of the corresponding alternator. On the left-hand side of the centre of the board are placed the four circuit panels, each provided with double-pole fuses, ampere-meter, and high-tension plug switch, just as for the alternators.

The current is brought from the 'bus cables at the back of the board, first through the plug switch, then through the fuses, and thence to the circuit through the ampere-meter. Between the alternator and circuit panel in the centre of the board is fixed a panel containing the double-pole exciter switches and fuses and the automatic knock-off switches for same. Three shunt regulating switches are provided for varying the E.M.F. of the exciters when throwing them into parallel; also a three-way voltmeter switch in connection with the voltmeter, so that the E.M.F. of any of the exciters may be measured. Above this panel is placed another containing the synchronising apparatus, and the high-tension electrostatic voltmeter and three-way voltmeter switch for measuring the E.M.F. of the pilot wires. Above the centre of the whole switchboard are placed a main ampere-meter, electrostatic voltmeter, and clock, the two former being connected to the 'bus cables. On the extreme right of the switchboard is situated the panel for the arc light circuit by means of rectifiers. On this panel provision is made for one circuit and two rectifiers. The leads from each rectifier are brought to the sockets of the double-pole four-break plug switch, and from thence are connected by means of the plug switch to a pair of fuses, and thence pass away to the arc light circuit through the ampere-meter. Below the ampere-meter is placed an electrostatic voltmeter measuring the E.M.F. of the circuit, and also a three-way voltmeter switch, so that the E.M.F. of the rectifier can be ascertained before plugging it to the circuit. By providing only one plug for the two sets of sockets, it is not possible to put both rectifiers on to the circuit at the same time.

The panels are of enamelled slate, 1½in. thick, fixed in a suitable varnished teak frame, the joints being covered with a varnished beading.

The whole of the switches are of the plug type, Fig. 16. The sockets for these are entirely encased in stoneware tubes, and are sunk very deeply in the board so that it is impossible to get a shock from them from the front of the switchboard. The plugs are mounted on an ebonite base set in a wood foundation, and are provided with suitable handles. The plugs themselves are also encased in ebonite, with the exception of the flat spring contacts at the end, so that it is impossible to get a shock when a plug is only partly withdrawn from its sockets. As the sockets extend over the metal at the back, they are also a protection at the back of the board.

The fuses (Figs. 17 and 18) are entirely mounted and encased in stoneware, and consist of a pair of clips, between which a porcelain bridge is inserted provided with terminals at the top and bottom. The fuse-wire is connected to these terminals, and threaded in and out through holes in the porcelain bridge so as to prevent any possibility of an arc forming from one terminal to the other on the fuse breaking.

The ampere-meters are of Messrs. Crompton and Co.'s manufacture, and are of the electromagnetic type, the dials being 8in. diameter, with the exception of the main ampere-meter at the top of the board, the dial of which is 12in. in diameter. In all cases the terminals are carried through the back of the instruments, and are encased in ebonite.

The high-pressure voltmeters are of the electrostatic type, and the low-tension voltmeters for the exciters are of the electromagnetic type, being also of Messrs. Crompton and Co.'s manufacture.

A synchroniser is provided at the back of the board, mounted on brackets and fitted with usual double-pole high-tension fuses. This synchroniser is connected by means of a pair of single-pole plugs to the 'bus cables, and is also connected to a pair of small 'bus cables, which are connected to a set of sockets on each alternator panel, and also to a double-pole plug switch on the synchroniser panel. A pair of plugs—one for the alternator and one for the

Digitized by Google

synchroniser panel—are provided to connect an alternator first to one side of the synchroniser by means of its plug switch on its own panel, and then when the machine is in phase it can be connected to the 'bus cable through a pair of light fuses, situated on the synchroniser panel, by means of a small plug switch on the same panel. After this is done, the alternator would be again connected to the 'bus bar by means of its own main switch. As only one plug is provided for the alternators, and as it is of a different size to that for the synchroniser panel, it is not possible to connect two alternators to the synchronising 'bus cables at the same time. The whole of the necessary plug and socket work for the above apparatus is mounted in ebonite.

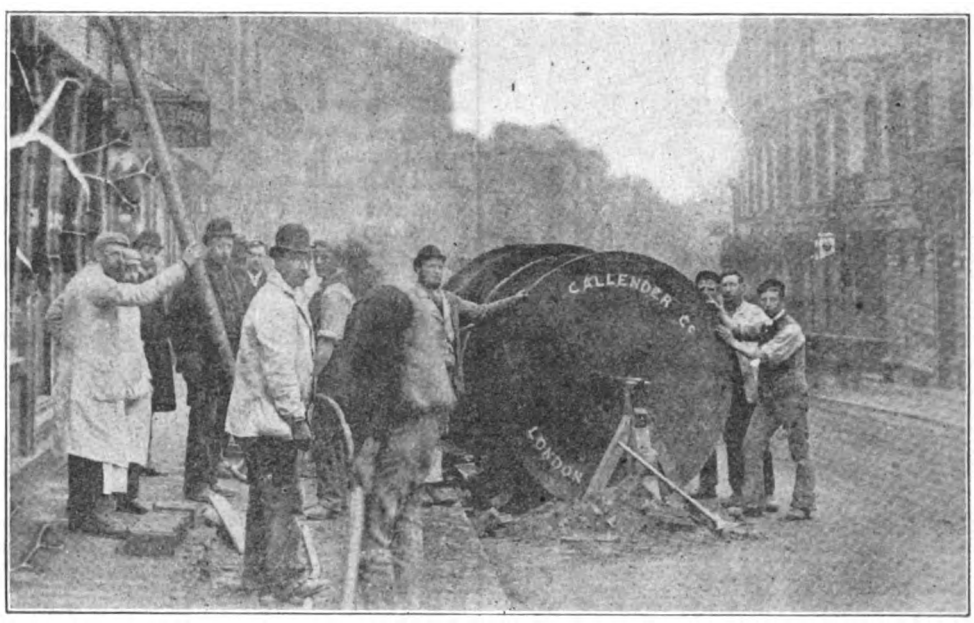

FIG. 20.—Laying Mains at Tunbridge Wells.

The exciting switches and fuses are of the usual low-tension pattern, the fuses being strips of fusible metal held between copper terminals, and the switches are of Messrs. Crompton's copper-foil S pattern. The three shunt regulating switches are of the circular pattern. The resistances for the same are mounted at the back of the board, and consist of platinoid coils wound on suitably insulated frames. The magnetic knock-off switches are of the usual type, and arranged so that upon the current falling to a minimum through the failing of an exciter or other causes, they automatically break circuit, thereby preventing any possibility of a return on the machine.

The slate panels are left bare at the back of the board, so that the terminals can be easily got at, but the whole of these terminals are suitably protected. In all cases where the high-tension connections pass through to the back of the board, they pass through quite clear of the slate or their ebonite or stoneware bushes, and no high-tension metal work is at any spot in contact with the slate. The connections at the back of the board are made by means of heavily insulated rubber cable. The resistances for the alternator field circuits are also mounted at the back of the board, and are constructed of platinoid wire wound on suitable frames similar to those for the shunts of the exciters.

Extensions are allowed for, so that an additional alternator can at any time easily be added by adding another panel to the right-hand side of the board. In the same way additional circuits can be provided for by adding panels at the left-hand end of the board, or if length is an object a second set of panels can be placed below the first. For additional synchronising apparatus, room is provided on the alternator panels. Spare panels for two alternators and exciters and three circuits are provided fixed in position ready to receive the necessary instruments and fuses.

MAINS AND DISTRIBUTING GEAR.

The distribution is on the high-tension system, the current being supplied direct from the generating station in Stanley-road to seven sub-stations through four high-pressure feeders and three sub-feeders. The system of supply will vary with the locality. A large proportion of the town consists of residential districts, containing gentlemen's houses standing in their own grounds. As a consequence, a large number of consumers will be found in outlying districts, where a low-tension system will not be at all economical for some time. In such cases a transformer will be placed in the houses. In the streets of the town low-tension distributing mains are being laid down wherever the demand is found sufficient. In the map of mains already laid, Fig. 19, the sub-stations are indicated by circles and the arc lamps by crosses in the streets. Also the lines indicate high-tension mains only, the low-tension distributors occur wherever the sides of the streets are cross-hatched. There is also an arc-light circuit laid throughout the chief streets of the town. The whole of the cables for the high-pressure feeders, low-pressure distributors, and arc-light mains have been manufactured and laid by the Callender Bitumen Telegraph and Waterproof Company, Limited, whose engineer on the work was Mr. H. Y. Schiassi. The type of cables employed throughout the

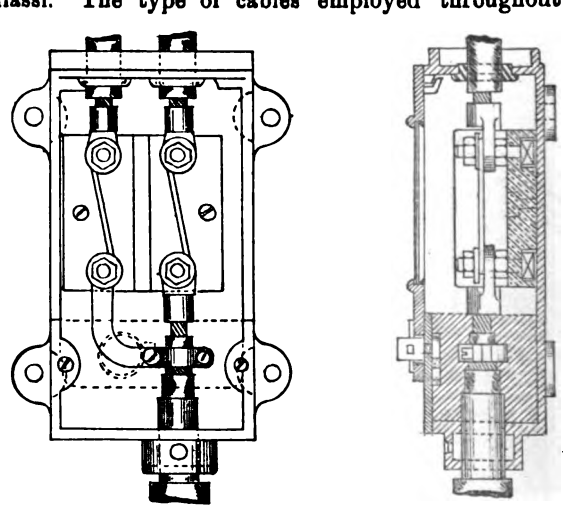

FIG. 21.—Reid's House Fuse Box.

whole of Tunbridge Wells is concentric, lead-sheathed, and armoured, and have conductors of the following sectional areas and lengths:

Feeder A, together with sub-feeder A, has an area of ·025 square inch, and is 1,817 yards in length. It runs from electric light station through sub-station 1 at the junction of Calverley-road and Mount Pleasant, thence *vid* Grosvenor-road to the Mount Ephraim sub-station. Feeder B, of ·035 square inch sectional area, is 1,800 yards

Digitized by Google

in length, and goes from electric light station to the sub-station 3 in High-street. Feeder C, also ·035 square inch, is 2,410 yards in length, and runs *vid* High-street, looping into sub-station 3, and thence *vid* the Pantiles to the sub-station at north end of the same, opposite to the pump-room. Feeder D runs from electric light station through sub-station 1, thence down Mount Ephraim-road and laid in 1895, together with their respective sizes, are as follow: ·025, 6,874 yards; ·035, 5,362 yards; 050, 1,350 yards; ·022, 3,796 yards; ·10, 2,781 yards; ·15, 1,175 yards; ·20, 85 yards. This gives a total length of about 12¼ miles, and it is a credit to Mr. Schiassi that this length has been successfully laid since January last. A view of the work in progress is shown in Fig. 20.

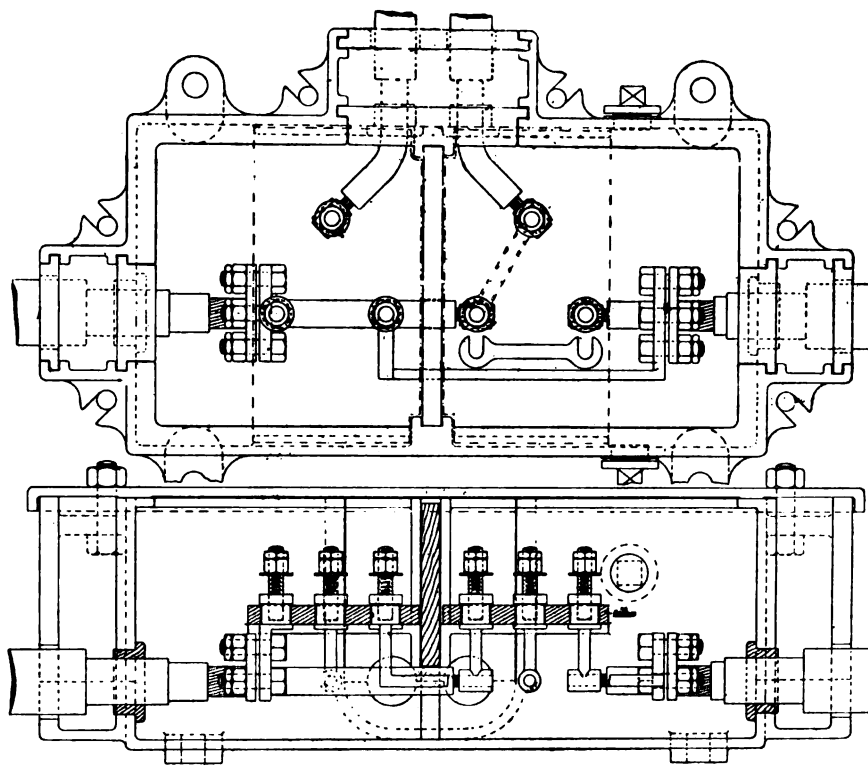

FIG. 22.—Transformer Connecting Box.

to the junction of London-road; this is 1,350 yards in length, and ·05 square inch sectional area. Sub-feeder D_2, ·025 square inch, is 1,170 yards in length, and runs from the junction of Mount Ephraim-road and London-road (where D ends) *vid* London-road to the transformer-chamber in Neville-street. Sub-feeder D_1, also ·025 square inch, is 860 yards in length, and is also run from where D

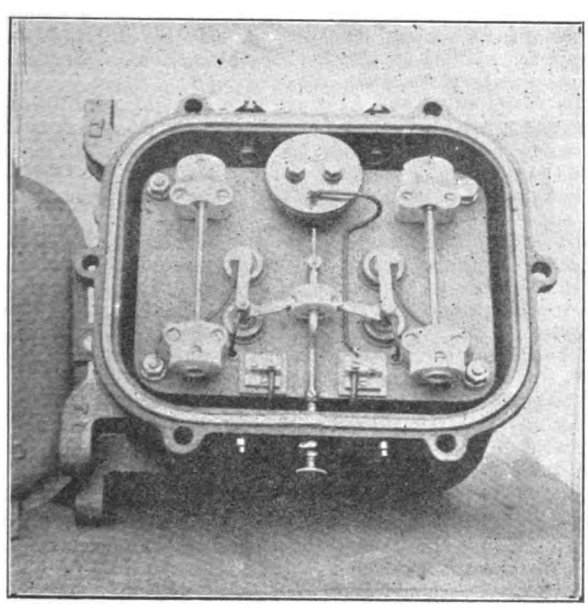

FIG. 26.—Crompton Transformer.

ends in Mount Ephraim-road along Mount Ephraim as far as the Mount Ephraim House. The arc lighting cables have a uniform area of ·022 square inch. At present only one circuit is used. The low-pressure distributing mains vary from ·10 square inch up to ·15 square inch and ·25 square inch sectional area.

The total amount of cable supplied to Tunbridge Wells,

House services are also laid on with concentric cable, lead-sheathed and armoured. These cables are of four sizes—*i.e.*, $^{7}/_{16}$, $^{7}/_{14}$, $^{19}/_{16}$, $^{19}/_{14}$—the services being joined to the mains in cast-iron boxes. The house ends terminate in Reid's fuse-boxes, as shown in Fig. 21. The cables, after being inserted in the box, are cast in with insulating compound to prevent the damp from running back up the cable. The transformer connecting boxes are shown in Fig. 22.

TRANSFORMER SUB-STATIONS.

These are excavated chambers under the footways of the general shape shown in Fig. 23, 24, and 25. The details vary somewhat with the space available.

The transformers (Fig. 26) were supplied by Messrs. Crompton and Co., and consist of a rectangular iron core with two coils wound on the two longer sides of the rectangle. Each coil has both a primary and a secondary winding, the primary winding being nearest the core. The insulation between these two windings and between the primary winding and the core consists largely of mica. These transformers are placed in cast-iron water-tight cases, fitted with a special type of water-tight gland bushed with stoneware bushes. The terminals are mounted on stoneware bases. All these transformers are tested to twice their primary voltage before being passed, and accurate measurements of the drop in loss on open circuits are taken.

In the design of these transformers, more particular attention has been given to the construction of a transformer that shall have high efficiency at all loads, and small drop in volts. The table below of efficiencies at a periodicity of 100, with some of these transformers, illustrates this:

Output of transformer in kilowatts.	30	15	10	8	3
Full-load efficiency, per cent....	97·8	97·3	96·8	96·4	95
Half-load ,, ,, ...	97 3	96 6	96	95 5	93·8
Quarter-load ,, ,, ..	95·3	94·4	93·3	92·7	89 8
Eighth-load ,, ,, ...	91·3	89·8	88	86·8	82
Open-circuit loss ,, ...	1·17	1·4	1·7	1·88	2·67

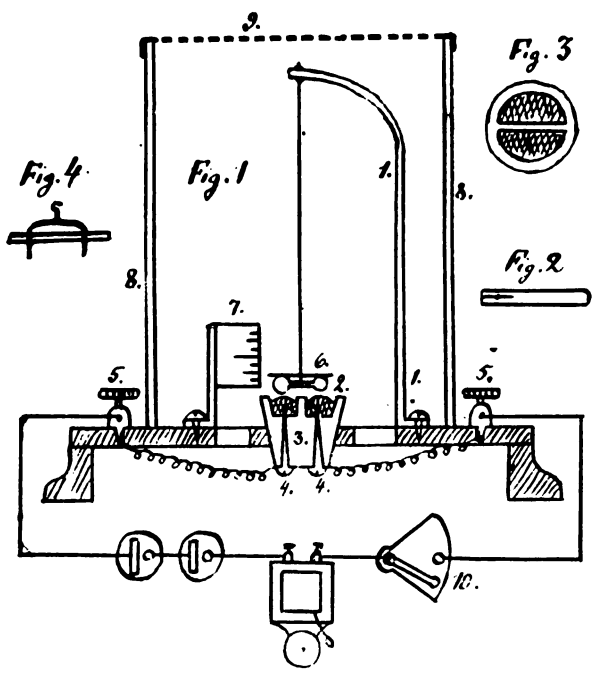
NOVEL APPLICATIONS OF ELECTRICITY.

BY R. W. HILL.

Herewith are the particulars of a simple, but efficacious, hygroscope with an electric attachment: Get a long hair from your lady friend, boil the hair for a while in a solution of soda, and one end of same attach to the brass or copper strip, 1 (Fig. 1), as shown in the horizontal section in Fig. 2. To the other end attach a tiny dumb-bell-shaped brass or copper, 2, electroplated with platinum. A small caoutchouc stopper, 3, is provided with two hollow apartments, as indicated in horizontal section in Fig. 3; put a few globules of mercury into them, and the two nails, 4, are connected by a wire to the two terminals, 5. To the brass, 2, is pasted a short piece of mica or straw, 6, and a small graduated paper scale, 7, is fixed near the suspended brass, as shown on the rough sketch. Cover the device with a glass cylinder, 8, provided with a cap made of wire gauze, 9, and the hygrometer is now ready. When the air is moist, the hair shrinks, and the brass will be lifted;



but when the air is dry, the little brass pendulum falls, closes the circuit of the bell, which will ring in a certain apartment in your house. In order to break the circuit, one-way switch, 10, is used. The stopper, 3, may be made movable, so as to adjust the alarm to any desired degree of humidity or dryness. The brass, 2, may be substituted by a short thick platinum wire with straw attached, as shown in Fig. 4.

Every chemist has experienced the difficulty of removing the glass stopper of a bottle when it has become fixed—apparently immovable. Of course, one of the best remedies is to heat the neck of the bottle for a while over a Bunsen burner. A serious drawback, however, of this old-fashioned method lies in the fact that the bottle must be held in a horizontal position, and the fluid or solution may be easily spilled out of the bottle if the operation is performed carelessly. I have solved this little problem in an up-to-date, efficacious manner by rigging up an adjustable clamp with coils of platinum wires embedded in a strip of asbestos attached to the said clamp. You press the circular clamp round the neck of the glass bottle, then "press the button, and electricity does the rest."

The last novelty is an electric annihilator of moths, flies, and the like-winged nuisance. It is an extremely simple though efficacious arrangement, consisting of an incandescent electric lamp placed inside a large glass globe, which is coated externally with a mixture of honey and wine or any other suitable sticky mass. Close the windows of the room, pull down blinds, close the doors, and make the room as dark as possible. Turn on the current, and a couple of hours later you will be surprised to see a lot of insects sticking to the said glass globe. The victims may be then "removed" with hot water, and the device is set afresh.

THE NEW BRITISH ELECTRIC INSTALLATION CONTRACTORS, LIMITED.

The official receiver's observations upon the failure of this Worcester company are of considerable length. The winding-up order was made on August 21 last, on the petition of a creditor presented on July 30, in respect of a debt for goods sold and delivered to the company, payment of which he had failed to enforce, although he had levied an execution, the whole of the company's property being claimed on behalf of the debenture-holders. The official receiver says:

The company was registered on October 29, 1892. Both the secretary (Mr. W. J. Hill) and the manager (Mr. J. H. Martin), who have attended upon me for preliminary examination, give the names of the promoters as Mr. J. Millington and Mr. J. Duce. The authorised nominal capital of the company was £25,000, divided into 5,000 shares of £5 each. Five of the signatories to the memorandum and articles of association appear to have treated the part which they took in the formation of the company as a formal and irresponsible matter (and it appears that they did not pay for any share or shares). The official receiver gives extracts from the original prospectus, which stated that the company was formed "for the purpose of acquiring and developing the business carried on by the British Electric Installation Contractors, Limited, at Worcester. The purchase-money of the business is fixed at £5,000, inclusive of all plant, stock-in-trade, etc., and payment is to be made partly in cash and partly in shares, as provided by the under-mentioned agreement. The company takes over the business as from November 1, 1892. The vendors pay the whole of the expenses attending the formation of the company."

It is alleged that such amounts as were subscribed in response to this prospectus were returned voluntarily. A supplementary prospectus, headed "private and confidential," was subsequently circulated amongst a limited number of local capitalists, without result.

The secretary of the present company was the liquidator of the old one. He was then, and still is, the chief clerk to Messrs. Griffiths and Millington. It was announced in the prospectus that the auditor of the company was Mr. Hubert Leicester, of Worcester, chartered accountant, but that gentleman informs me that he was not aware that he had been appointed auditor, and that he never conducted any audit of the company's affairs. The present solicitor, Mr. A. J. Beauchamp, has notified me that his appointment as solicitor of the company was not made till July, 1894.

The directors of the company have been Mr. J. Millington (chairman), Mr. J. H. Martin, and Mr. R. J. Surman. The last-named gentleman writes: "As I did not feel at all satisfied with the method of working, I sent Mr. Hill, the secretary, my resignation, dated February 10." The vacancy thus created was apparently not filled.

Mr. J. H. Martin, who was specially named in the winding-up order as the officer of the company required to wait upon me in reference to the affairs of the company, denies that he had anything to do with its promotion. He alleges that he was induced to join it by the offer of a joint managership, at a salary of £2 per week, which salary he admits receiving from February, 1893, to July last. He is now the holder of 46 ordinary shares and 500 debentures, in respect of which he asserts that he has paid the full value thereof. He also states that he was not cognisant of the true position of the responsibilities of the new company at the time he agreed to take up the 46 shares. Since the statement of affairs was lodged I have received a letter from him as follows:

"In lodging the sheets this morning with statement of accounts, there is on sheet F a note that the £500 that I lent to the company should rank *pari passu* with the other debentures. This I most strongly object to, as the first debentures are made up of bonuses and shares allotted free to the promoters, whereas mine is actual money lent to the company with the understanding that I was to be repaid out of the first moneys received, and when I asked for security these debentures were offered as the only security I could have for the loan, so I most certainly think mine should be a prior claim."

At the first meeting of the directors of the new company, held on February 11, 1893, it was resolved:

"That the following arrangement for the purchase of the business of the British Electric Installation Contractors, Limited,

Digitized by Google

be confirmed, that the chairman be authorised to carry out the details thereof, and that the seal of the company be affixed to an agreement containing such provisions.

"That the purchase-money for the business of the British Electric Installation Contractors, including all plant, machinery, stock-in-trade, standards, poles, instruments, wires, fittings, wayleaves, rights-of-way, book debts, contracts and agreements, be the sum of three thousand pounds (£3,000), this company also taking over the existing liabilities of the vending company, it being understood that the value of the business is £3,200, and the balance of liabilities over book debts £200."

A formal agreement between the two companies for the payment of £3,000 6 per cent. first mortgage debentures, with a covenant to pay the liabilities of the old company, which, I understand, exceeded £500, was executed by John Millington as director of the old company, and James Duce as secretary, and by James Hugh Martin as director of the new company, and W. J. Hill as secretary. In his preliminary examination the secretary, who, as I have already pointed out, was also liquidator of the old company, stated that he did not fix the amount of the purchase-money; that there was no independent valuation; but that he believes the amount was arranged "by Mr. Millington and Mr. Duce, who were interested in both companies."

At extraordinary general meetings of the company, held March 11 and April 8, 1893, at which only four persons were present—viz., Mr. Millington, Mr. Martin, Mr. Duce, and the secretary—authority was given for the issue of £3,500 6 per cent. first mortgage debentures, as part of the authorised capital of £25,000; and at a subsequent meeting of the directors, held in July, 1893, the secretary was "instructed to issue debentures to the liquidator of the vendor company, as the purchase-money of the old business, for distribution among the vendors, such debentures to be filled up in such names as he may require." The debentures were, so the secretary informs me, "divided amongst the old shareholders upon the basis of their claims and interests in the old company, with a bonus."

The debentures were allocated thus:

Messrs. Griffiths and Millington	£1,400
Mrs. H. Duce	400
Ditto	650
Mr. Millington and Mr. Terry, trustees of Mrs. A. M. Duce	425
Mr. R. J. Surman	125
	£3,000

From further particulars supplied by Mr. Hill, I find that the debentures were appropriated in discharge of the following items:

Capital subscribed in cash by shareholders in the old company	£810
Promoters' shares allotted in respect of services rendered in the way of promoting the company	500
Cash advances to company	1,200
	2,510
Bonus added	490
	£3,000

Upon my enquiring of Mr. Surman the circumstances under which he obtained debentures in the new company of the value of £125 in lieu of the £100 shares which he held in the old company, he replies: "The £125 debentures were handed to me by the secretary, but I do not recollect why the company made the amount £125 instead of £100, unless it were in lieu of broken promises."

On January 27, 1894, the directors resolved "that the unallotted debentures, amounting to £500, be issued to Mr. Martin as security for his advances."

The debentures were of a wide character, embracing "the freehold and leasehold premises, plant, stock, licenses, book and other debts, property, goodwill, assets, and undertaking of the company, both present and future, including uncalled capital for the time being of the company as a floating security for the payment of the principle and interest for the time being due on this debenture."

The ordinary share capital of the company was represented thus:

Shares allotted to the seven signatories, one each of £5	£35
Mr. J. H. Martin, 46 ditto	230
Mr. J. Millington, 47 ditto (held on behalf of Mrs. A. M. Duce)	235

The following shares were subsequently paid for:

June, 1894, Mr. David Harper, 20	100
July, 1894, Miss R. Wheatley, 40	200

making the gross total of the share capital £800.

At a directors' meeting held on May 26, 1894, Mr. Millington reported "that he had been in negotiation with several gentlemen with a view to increasing the capital of the company, and that Mr. Harper had promised to invest £100." It is also recorded at the same meeting as follows: "Mr. Martin expressed his willingness to invest a further £100; Mr. Surman £50; Mr. Millington £100, provided £500 was invested altogether." Neither of the directors appears to have taken up these shares.

At a directors' meeting on July 18, 1894, the chairman reported that he had seen Mr. H. Turner, who had agreed to take £400 worth of shares in the company, and that he had communicated with Miss Wheatley, who had agreed to take up £200 worth of shares. A resolution was passed "that letters of allotment be sent to those two persons, and that the share certificates be issued and sealed with the seal of the company." Mr. Turner's shares were apparently not taken up.

It will be noted that, with the exception of Mrs. A. M. Duce, the ordinary shareholders in the new company do not apparently include as *bonâ fide* subscribers any of the persons who obtained the debentures in respect of their claims upon the old company.

The old company was registered in October, 1891. It was wound up voluntarily, and I have therefore no precise information as to its affairs. But the particulars set forth below may not be uninteresting as illustrating its financial position. The following paragraph is extracted from the petition:

"The old company was insolvent, and its shares valueless. The new company has been formed for the purpose of converting the shareholders in the old company who were debtors to the old company (inasmuch as they were the holders of shares in the old company credited as fully paid in respect of which no cash had been paid and no contract had been filed with the registrar of joint-stock companies) into secured creditors of the company."

Amongst the papers which have been handed to me by company's officers, I have found what appears to be a copy of a balance-sheet relating to the affairs of the old company. [This represents the position of the company from the time of its incorporation: no dividends, debenture interest, or other profits having been paid.]

The books of accounts which have been produced to me appear to have been kept in a very loose and imperfect manner. Many of the company's transactions have been passed through a private banking account of Mr. J. H. Martin. The secretary states that he has not had anything to do with the books of account, and that they have latterly been under the supervision of Mr. J. H. Martin. The question of book-keeping was discussed at a directors' meeting held May 26, 1894, when it was resolved that "provided the additional capital required is raised, the books should be kept at 50, Foregate-street, and that 25s. per week should be paid to Messrs. Griffiths and Millington for so doing." This arrangement does not appear to have been carried out.

What has been produced to me as the company's general cash-book appears, as to very many of its entries, to have been compiled at one and the same time. The receipt side of the book is only cast in pencil; the payment side is not cast at all, and the last payment recorded therein is made under date September 26, 1893. Against some of the receipts there is a remark in the cash-book, "Pd. Bank," but I cannot trace that these moneys were paid into the company's account; other receipts appear to have been handed to Messrs. Griffiths and Millington to repay them cash advanced for the benefit of the company, but I do not find such transactions properly recorded in the books produced to me. The pages of the cash-book are not numbered, and some of the entries are inaccurate. In some cases moneys were collected from the company's customers, and receipts given, but the company's official receipt forms were not used. Many of the company's transactions do not appear in the ledger. Entries appearing as credits in the ledger do not correspond with the cash-book, and cash credited as being subscribed by the shareholders cannot be properly traced either in the general cash-book or bank pass-book. In fact, the company's affairs, so far as they are exhibited by its books of accounts, are in a state of chaos. A letter has been received by me from Mr. Martin, in which he states:

"I made the stipulation when I joined the company that I was to have nothing whatever to do with the book-keeping, as I did not understand it. Further, a minute was made at a directors' meeting in the early part of 1894, that the books were to be kept at Messrs. Griffiths and Millington's, but after they had been there some months I enquired and found the books had not been kept. I had them back to our office and made an effort to put them in order."

The secretary attributes the failure "in the main to insufficiency of capital," but he adds, "I have not personally had the active management." My own opinion as to the precise causes of the failure I, for the present, withhold; but I may point out that as the old company had an authorised capital of £20,000, of which not one-twentieth part had been subscribed in cash, further information appears to be necessary as to why the new company was ever brought into existence.

The statement of affairs has been submitted by Mr. Hill and Mr. Martin. The unsecured liabilities are principally owing for goods supplied to the company. Two or three of the principal creditors, with whom I have communicated, inform me that they were not, at the time of supplying the company with goods, aware that such goods were subject to the debentures

Digitized by Google

immediately they reached the company's premises. All the property of the company is claimed by a receiver, who was appointed on behalf of the debenture-holders on July 19 last.

The deficiency of £4,722. 16s., plus £1,977. 12s. 2d. (added in respect of the company's gross profits since its formation), and making a total of £6,700. 8s. 2d., is explained by the secretary and manager thus :

I. Expenses of carrying on business from date of formation of company to date of winding-up order—viz. :

	£	s.	d.
Salaries and wages	2,506	10	11
Rent, rates, and taxes	115	0	0
Miscellaneous trade expenses	355	14	11
Depreciation written off in company's books	—		
Interest on loans	54	0	0
	3,031	5	10

II. Depreciation on property not written off in company's books—viz.:

Electrical standards and other fittings erected in anticipation of development of lighting	150	0	0
Stock-in-trade	250	0	0

III. Other losses and expenses (if any) from date of formation of company to date of winding-up order—viz. :

Difference between amount of debentures issued to, and liabilities of old company, and tangible assets received in consideration	2,699	2	4
Expenses of formation (printing, postage, advertising, etc.)	320	0	0
Loss on Ledbury contract	100	0	0
Legal expenses, costs, etc.	100	0	0
Expenses of removing from 21, Broad-street to The Avenue, and additional expenses caused through obstruction of entrance	50	0	0
Total amount accounted for	£6,700	8	2

Mr. Luke J. Sharp adds : "This report has been prepared with the object of giving the creditors as much information as possible for the purposes of transacting the business at the first meeting ; but as the statement of affairs and books were not lodged with me till September 16, and such books are incomplete, I have not had time to make an exhaustive investigation of the company's affairs."

The summary of the statement of affairs shows, as regards creditors, that the company's gross liabilities are £4,363. 18s. 8d., of which £3,922. 16s. is expected to rank for dividend. The estimated assets are : stock-in-trade, £280. 5s. 9d. (estimated cost, £370. 12s.); trade fixtures, fittings, and utensils, etc., £9. 18s. 2d. ; good book debts, £150. 18s. 6d. ; a total of £441. 2s. 5d. ; deduct loans on debenture bonds secured on the assets of the company, £3,500 ; estimated deficiency of assets to meet the liabilities of the company, subject to the cost of liquidation, £3,922. 16s. The nominal amount of unpaid capital liable to be called up to meet this deficiency is nil. As regards contributories, the statement shows that there were 160 ordinary shares of £5 per share (11 shareholders) called up, adding another £800 to the liabilities, and making the total deficiency of the company £4,722. 16s.

PORTRUSH ELECTRIC TRAMWAY.

BOARD OF TRADE ENQUIRY.

Major Cardew, R.E., opened a Board of Trade enquiry on the 25th ult., in the Town Hall, Portrush, concerning the fatal accident which occurred on the electric tramway on August 2 last.

Mr. Wm. Moore, barrister-at-law (instructed by Mr. Thomas Taggart), represented ratepayers who are opposed to the present system upon which the cars are driven ; and Mr. H. W. Leech, Coleraine, appeared for the Electric Tramway Company. Lord Macnaghten, Viscount Templetown, Sir Francis E. Macnaghten, Bart., H.M.L., County Antrim, Prof. Fitzgerald, M.I.C.E., and Dr. Trail, F.T.C.D., were present.

The **Inspector** stated that he had been appointed by the Board of Trade to hold an enquiry into the fatal accident which occurred on the electric tramway on August 2 last. The Board of Trade had received complaints from various ratepayers, and he thought the best way would be for those complaints to be investigated first. After that they would hear what the company had to say in their defence.

Mr. Moore stated the case for the opposing ratepayers. At the outset he referred to the Acts of Parliament under which the tramway was worked. He pointed out that under the Act of 1880 the railway only extended from Bushmills to Portrush. In the year 1885 the company obtained another Act empowering them to construct a railway from Bushmills in the direction of the Causeway. The first railway was some six miles in length ; the additional railway was a little over two miles. In consequence of the lengthening he understood that increased water power was required, additional machinery was erected, and that larger engines were put up at the depôt at Bushmills. Now, what the ratepayers objected to was this—there was no security to the public, nor was there any advantage conferred upon the ordinary traffic by this electric tramway company. People who were accustomed to drive their cattle along the road—the highway—now made detours rather than expose their animals to the risk of contact with this electric rail What the Board of Trade would have to do would be to decide what were the proper precautions to be adopted if the tramway was to continue, having regard to the ordinary requirements of the public traffic. On behalf of his (Mr. Moore's) clients he intended to make proposals at the termination of the enquiry as to how the tramway should be worked, and he would suggest that the question of expenditure, whatever it might be, should not be considered where the public safety—life and property—was involved. If it be necessary, as he would ask them, to hold on scientific evidence that this third rail, which was now elevated some foot and a half above the surface of the road, should be removed, and another system—underground or overhead—adopted, the matter of expense, he submitted, was unimportant. This electric current had not only killed cattle, but had, unfortunately, deprived a human being of his life. If this tramway company were permitted to proceed in the manner they were now doing, no one could tell what the result might be. Counsel having alluded to the voltage at the generating station, directed attention to the fact that there was no automatic record kept, and read correspondence which had taken place between the company and ratepayers. If a man were driving a beast along the road he must be ever at its side, and the risk run was very great. In 1884 a Board of Trade enquiry was held into the working of the line, and it was decided that a notice cautioning persons of the danger would be sufficient. With great respect to the Board of Trade, he might ask what safety a poster offered to an ignorant bull or a person who could neither read or write? As representing a large number of ratepayers in the district who had lost cattle, he asked that some proper protection should be afforded, and that the present arrangement be prohibited.

Sir Francis Macnaghten was the first witness called.

Mr. Moore : Have you seen cattle injured on the line?—I have seen the dead bodies of cattle on the line and efforts made to resuscitate them. David Douglas lost a cow, and I saw a grey horse killed by the current up at the quarries.

The **Inspector** : Did you see any marks of burns upon them?—No, I did not examine them.

In answer to **Mr. Leech**, **Witness** denied having opposed the tramway from its inception, but he believed it had become a nuisance Shortly before 1884 he complained to the Board of Trade, and correspondence had taken place.

Somerset Fairley, cattle dealer, Coleraine, stated that a bullock of his was killed through coming in contact with the rail. After the accident he was afraid to fetch his cattle along the road.

Lyle Taggart, who has a farm between Bushmills and Portrush, said that in June, 1893, he was driving six cows and a bull along the road. Some of the cows had been shocked before, so they kept away from the rail, but the bull, which he had only a short time, touched the rail and fell. Witness rushed forward caught him by the tail, and pulled him off. Death ensued, however, in about five minutes.

By **Mr. Leech** : There was a ring in the bull's nose, but he had no rope attached. The bull was looking for grass, and happened to touch the rail with his nose. He immediately fell, struggled, and died. In pulling him off the rail they were shocked. At the present time witness admitted having grass sublet adjacent to the railway.

Hugh Macauley, labourer, remembered working at hay about four years ago contiguous to the Bushmills depôt, when he saw a cow with her right foreleg over the rail. Mr. Chambers, in the employment of the company, cut off the current, but the animal roared and died. Mr. Douglas owned the beast. Witness had seen the body of the cyclist, Thomas Walne, who was killed, and it was greatly discoloured.

Daniel M Mullan said he recollected the accident to John Hall's horse 10 years ago. It occurred on the Portrush side of Bushmills. A man named John Russell was driving. He wanted to get on the horse's back, and for that purpose drew the animal up close to the bank where the rail was. The horse touched the rail with his foreleg, and he fell. Witness ran to Russell's assistance, and they endeavoured to drag the horse away, but they had to let go because of the current. They then procured a rope, but the animal was dead when they got him off.

Dr. Traill remarked that although the company had paid compensation in several cases, they disclaimed entirely any liability.

Other evidence was given of the killing of cattle by contact with the conducting rail, and of complaints made to the Grand Jury by the cesspayers.

Samuel Cooper said that a servant girl named Jane Callaghan in his employment received a shock through simply touching a paling wire. It seemed that the current was communicated through an iron bar, which was resting against the electric rail. The girl could not let go, and witness experienced difficulty in dragging her away. She was unable to work for days owing to the soreness of her hands, which were burned.

At this stage the enquiry was adjourned until the following morning.

Upon the resumption of the enquiry, **Arthur E. Porte**, an electrical engineer of 20 years' experience, said that he had examined the generating station on the previous day. The pressure at the Bushmills station was 290 volts. There was one car on the line at that time. He would expect the voltage to be considerably higher if the number of cars were larger. There was not an automatic brake or governor on the cars, so far as he could see, nor was there an indicator to show the speed. There was not an efficient governor

Digitized by Google

on the turbines at Bushmills. The speed indicator attached to the dynamo was not efficient, inasmuch as it was indicating wrongly when he saw it. The voltmeter could not be read at a distance of 18in.—he himself had not been able to read it at 6in. He did not see notice boards fixed in the electric generating station at Bushmills stating the maximum speed of the generator. He had made no leakage test, and could not say what waste might take place in the current along the line. There were a great many insulators broken and missing, and in wet weather there would be leakage. If there was a heavy load the resistance would of course, be greater, and would necessitate a higher pressure at the Bushmills end to maintain 250 volts at the Portrush end. He considered the line not safe as at present working up to 290 volts, having regard to the ordinary traffic of the road. There was possible danger to human life

Mr. Moore: You have considered the matter, and in your opinion how would you propose at the lowest possible cost, in fairness to the company, to put matters in a safe condition for the public?—I would cover in the rail so as to prevent contact with it, and still leave room for the connectors to travel on it.

Now, what sort would your covering be?—Preferably iron, but wood would do.

Only for the top and partly down the side?—Principally on the top. It might lap over a little on the side on which the traffic is.—And the shape of the tongue or slipper could be altered so as to catch the rails as at present?—Yes

Now, as to the turbines, would you propose any alteration in the present method of governing them?—I would like to see them governed automatically.

The **Inspector**: Would you link these governors with the electric circulators?—Yes, preferably. Continuing, witness said he would recommend a self-regulating voltmeter open to public inspection at the Bushmills junction, and more frequent inspection by officials

Mr. Porte was cross-examined by Prof. Fitzgerald with a view of showing that his proposed precautions were not absolutely necessary to the public.

The **Inspector**: If an electric conductor can be easily protected so that it will not be touched, there is no adequate reason for its remaining unprotected?

Mr. Porte: That is my point.

Further questioned, **Witness** said there would be considerable danger to a child by coming in contact with the rail.

By **Mr. Leech**: He had made no estimate of the probable cost to the company of the alterations he suggested. That was not within the scope of his investigation, but he should say, as compared with the cost of putting the rail overhead, it would be as the difference between hundreds and thousands.

The **Inspector**: In your opinion, if a person was drawn on to this rail, so as to press upon it with all his weight, would there be a greater chance of his sustaining injury than if he touched it of his own free will?—Yes, very much greater.

Mr. Moore closed his case by handing in the notes of evidence and verdict of the coroner's jury.

Mr. Leech, in replying, said the notice of enquiry which he had received certainly led him to the conclusion that the enquiry was to have reference to the unfortunate accident which led to the death of the young man Walne, but the proceedings had taken an entirely different course, for they had been dwelling upon the lamentable and deplorable deaths of heifers, cows, and horses. He always expected Mr. Moore to come to the point of the enquiry, but he showed them he was not going to grapple with a matter of such difficulty and doubt when he had plenty to satisfy his clients by assailing the Messrs. Traill about these dead animals. In the 12 years from 1883 to 1895 there had been nine animals killed. There was not the slightest doubt that there was an influential body of ratepayers personally opposed to the Messrs. Traill, or the tramway company, if they liked to put it so. But subscriptions were easily raised. After all, they had only proved the deaths of nine animals in 12 years, and some of the evidence, indeed, was second-hand. To bring it to vulgar fractions, it meant three fourths of an animal per annum. This was not such a matter as would induce the Board of Trade to interfere with the working of the line, or to place restrictions upon it which were not necessary to the safety of the public. The killing of the cattle did not strictly come within the scope of the enquiry, but he had not objected because it led up to the case which ought at least to have been attempted. The line had been laid for the public advantage, and there was also the benefit of a footpath from Bushmills to Portrush, without any cost to the county. It was illegal, of course, for a person riding a bicycle to use that footpath, but as such it was used along its entire length. Having argued that Walne had no right to attempt to get on the footpath with his bicycle, that it was probable that the great force with which he was thrown off the bicycle against the electric rail might have caused death, and that the Board of Trade regulations had all been complied with by the company, Mr. Leech concluded by stating that a weaker case had never been presented—in fact, there was nothing to meet but the overwhelming eloquence of eminent counsel brought down from Dublin.

David Christie said he had lived in Portrush for the past 33 years. He had not the slightest interest in the railway. He had been in the habit of taking shocks by catching the elevated rail with his hands.

The **Inspector**: What did you take them for?—For mere curiosity. He had taken them in all sorts of weather, and had felt no ill-effect. When the rail was wet he had caught it without any injury being done. On one occasion he sat down on the rail to rest himself, with his feet upon the ground rail. He received a slight shock, but it did him no harm. He had once struck the electric rail with a piece of iron and produced sparks. Tourists were wont to do the same thing out of curiosity.

James Lecky, manager Portrush gasworks, said he, too, had taken shocks for curiosity. He had known rheumatic people come specially to Portrush to get at the electricity, as it had the name of doing them good. Witness had caught the rail when wet, and taken shocks very near the generating station.

John M'Kay stated that he had frequently taken shocks when the rail was both wet and dry, and found no ill-effects. He had seen other persons touch the rail.

James Boyd, inspector of the line, had also frequently taken shocks—of his own accord and otherwise—under different circumstances and in all kinds of weather. On one occasion, when the chain of a car got deranged on a journey, he had of necessity to lie on his back to get at the injury, and during all that time—15 minutes—his head was leaning against the rail through which the current was passing. He felt the shock, but he was not in any way injured. His head was not singed. A drunken man fell asleep across the rail, his neck touching it. Witness was driving the electric car at the time, and was within an ace of running over him, as it was at night and very dark.

By **Mr. Leech**: The current was on at the time; just at the same pressure as when the unfortunate cyclist lost his life. Witness had made various experiments. He had touched the rail with wet grass to test the effect. He received shock, but no injury. In 1885 a horse bolted on the road, and struck the rail with his forelegs. They had difficulty in getting the animal off, but he was not injured. A few hairs were taken off. The driver also touched the rail, but was not injured. Witness gave several instances where people and horses struck the conducting rail without receiving any harm. A horse and cart one time ran into the engine, and got so wedged in between the electric rail and the tram that great difficulty was experienced in extricating them, and a considerable time elapsed. Three of the driver's ribs were broken, but he was in no wise injured by electricity, although he was pressed against the rail. He had seen Mr. John Taggart make a horse touch the rail, and the animal received no injury. He had also seen a man mount a horse by stepping on the rail. It was a usual thing for children down at the Causeway to catch the rail for fun, and still no harm was done.

Prof. Fitzgerald was then called, and examined by **Mr. Leech**.

You are well versed in electrical science?—Yes.

In your opinion is there any danger to a person up to 250 or 300 volts?—No serious danger.

Is there danger to cattle?—I think there is.

The **Inspector**: Why do you think that there is danger to cattle and no danger to human beings?—Because of the many experiments that have been tried. Drunkenmen and others have touched and lain upon the elevated rail while the current was passing, and no injury had resulted. On the other hand, cattle and horses, according to the evidence, had been killed.

Prof. Fitzgerald: I think the jury were dissatisfied as to the cause of the death of the cyclist. If they had intended to say that the electric shock killed the man they would have said that death was due to the current It certainly was an extraordinary case.

Mr. Leech said he had several other persons ready to be examined, if thought fit, who had caught the rail and sat down on it without any ill-effects, but he did not consider their evidence necessary. It would be merely corroboration, and he did not wish to unnecessarily prolong the enquiry.

Mr. Moore then made a few remarks. He pointed out that the enquiry was not held simply into the fatal accident which unfortunately had occurred, but into the entire working and condition of the line. The death of the cyclist had only brought things to a head The Acts of Parliament referred to gave the company no authority to use the rail in its present position, but when constructed the Board of Trade approved of it, and he supposed the same Board would have power to order its removal. And now that it had been proved that the rail was a source of danger, he submitted that the Board of Trade were bound, in the interest of the public, to have the rail so safeguarded that those dangers would cease Although the company had never admitted liability, they went so far as to recognise that they were in the wrong by paying compensation in almost every case of accident. If the Board of Trade came to the conclusion that the electric rail was dangerous—and he asked them to decide that it was—the electricity could be stayed until proper safeguards were constructed. And the company need not suffer in the least, for they had steam-engines which would prevent any suspension. He might also suggest that there ought to be automatic governors on the turbines.

The **Inspector** said he would send in his report, and the Board of Trade would give their decision in due course.

COMPANIES' MEETINGS AND REPORTS.

FROGGATT'S ELECTRIC LIGHTING COMPANY, LIMITED.

The first annual general meeting of this Company was held on September 30 at Winchester House, E.C., the chairman of the Company, Mr. A. de Murrieta, presiding.

The report, which, with the statement of accounts, is made up to May 31, says:

"The general progress has been, on the whole, satisfactory, though hardly equal to what the directors expected. Several contracts have been secured, among the most important of which may

Digitized by Google

be mentioned the London Tramways Company, Limited, the Glasgow Corporation Tramways, and the proprietors of the leading South London omnibus services. The Board have the pleasure to report that applications are continually being received for the lighting of omnibus and extensive tramway services in the Metropolis and other populous centres in the United Kingdom, as well as on the Continent, and together with the enquiries which are increasing day by day for agencies to retail the various specialities manufactured by the Company, justify the expectation that a large business will result, more especially considering the experience that the directors have now acquired. In order to successfully carry out the various contracts entered into, and for the purpose of manufacturing accumulators and other fittings for this branch of the business, almost the entire outlay of the called-up capital has been necessitated, and as two of the principal contracts are not yet completed, and the majority of the others have only been running a few months it is not surprising that the accounts show a balance (£1,236. 12s. 8d.) to the debit of profit and loss account. A further cause which has contributed to this result is the fact that a large number of advertising discs, consequent upon the incompletion of the two contracts referred to, have been unproductive; also that it has necessarily taken time to secure customers for those that have been available, but as their undoubted value is rapidly becoming known to advertisers, and as improved arrangements have been entered into with the Company's agents (Messrs. Willing and Co., Limited), the directors have every confidence that these drawbacks will very shortly be overcome In the capital account shares to the extent of £17,120 remain to be issued, but having hitherto had sufficient capital for their requirements the Board have considered it was more in the interest of the existing shareholders that further shares should only be issued when money was required. It is, however, proposed to ask for further subscriptions, but only in such quantities and at such intervals as may be deemed necessary. On December 13, 1894, the Honourable Chandos S. Stanhope joined the Board as a director of the Company, and in informing the shareholders that he has, owing to ill-health, been obliged to leave the country, and has since felt impelled, on account of his continued absence, to resign that position, the directors are certain that the regret they feel at these circumstances will be shared by all."

The **Chairman**, in moving the adoption of the report, said that it was a very great disappointment to the Board that it was not a more favourable one. In all new businesses the first year was always very difficult, and in their case they had found it full of difficulties, especially in regard to that branch of their business which related to the lighting of public vehicles. With the experience they had, however, they were confident of overcoming these difficulties. Under present contracts they were supplying 500 lights for the London tramways and 800 for the Glasgow tramways. They had also sold some apparatus for lighting omnibuses in the Isle of Man. The extension of this branch of their business required serious consideration, owing to the capital it absorbed, and also because of the rough treatment their batteries were subjected to, owing to the class of men they had to employ. However, an arrangement had now been come to with the London Tramways Company by which their own staff did the work, and the directors intended to propose a similar arrangement to the Glasgow Corporation. The Board had been disappointed with the returns from their advertising discs They had secured long contracts for advertisements, and they hoped to make further progress with the empty space still at their disposal. They were now devoting more attention to portable lights for houses, bicycles, travelling and policemen's lamps. There was another branch they had in hand, the details of which he thought best not to mention, except that a very influential firm had approached them with a view of securing the agency for it. The directors had given their services without remuneration, and though they had not been able to realise any profits they had devoted much more time and attention to the business of the Company than they had ever contemplated would be necessary. A considerable amount of friction and disagreement had arisen on the Board and between the Board and the manager, and they thought it was very advisable that the shareholders should appoint a committee to confer with the directors with a view to reorganising the Board.

Dr. Macgill, managing director of the London Tramways Company, seconded the adoption of the report.

Mr. Diamond said he should like to propose the name of a gentleman to serve on the committee.

Mr. H. Keeble, the Company's solicitor, said that could not be done that day.

The report was carried, and some further conversation took place as to when the meeting would take place for the election of the committee, both the Chairman and Mr. Hackforth Jones stating that it would be as soon as possible, though a precise date could not be fixed.

The retiring director, Mr. C. de Murrieta, and the auditors, Messrs. W. P. Eldred and Co., were then re-elected, and the meeting closed with the usual votes of thanks.

HAWAIIAN TRAMWAY COMPANY, LIMITED.

The eighth ordinary general meeting of the shareholders of this Company was held on September 30 at the Cannon-street Hotel, E.C., Mr. H. R. Armstrong presiding.

The **Chairman**, in moving the adoption of the report, which recommended a dividend at the rate of 1¼ per cent., leaving £41 to be carried forward, stated that the cause of the decline in the profits was the enforcement of martial law, which had been necessitated by the change from a monarchy to a republic. Owing to this the hours of movement were curtailed and the usual pursuits of the population were upset. The profits of the Company had thus been reduced by about 5,000dol., but if the traffic returns of the past few months were maintained they would do very well. An omnibus proprietor had for some time been running against them, and in order to protect their interests it had been necessary to start omnibuses of their own and "nurse down" the opposition, as it would have been very bad policy to buy it out. They obtained permission from the Legislature in 1890 to use electric traction, but up to the present they had been unable to recommend its adoption to the shareholders, owing to the expense both of the installation and conversion. In America electric traction was greatly used, and no doubt it had an advantage in many instances over horse traction. Some company promoter brought forward a Bill for electric traction in opposition to this Company's, but the measure was thrown out in Honolulu. There still, however, remained a desire for electric traction on their tramways, and the directors were taking every step to enquire the price of the conversion and the cost of generating and renewal. It was very difficult to obtain correct details as regarded renewal, electric tramway accounts not yet being perfectly clear on this head. They would wish to convert, run, and renew themselves, but they must be assured that the shareholders would receive benefit as well as the travelling public. When they had the whole information ready, they would report the fact to the shareholders and call a meeting of them before going any further in the matter.

Colonel C. E. Macdonald seconded the motion, which was adopted.

WILLANS AND ROBINSON, LIMITED.

Directors: Mark Robinson, M.I.C.E. (chairman), Sir Gilbert A Clayton-East, Bart, Captain H. Riall Sankey, R.E. (Ret.), M.I C.E.

The third half-yearly report of the directors, to be submitted at the ordinary general meeting of the Company, to be held at the City Terminus Hotel, Cannon-street, E C., at 3 p.m. on Tuesday, October 8, 1895, states: The accounts for the third half-year of the Company's operations, ending June 28, 1895, are submitted herewith. The engine orders in the half-year amounted to 12,832 i.h p., against 10,315 in the corresponding half of 1894, and 9,290 in that of 1893 (old company). As previously pointed out, the Company has great difficulty in keeping pace with its orders, and the fast increasing demand for the Willans engine, though encouraging for the future, is only a source of embarrassment in the present, and must continue to be so until the new works at Rugby are completed. Notwithstanding this serious drawback, the result of the half-year's work is satisfactory. After writing off as depreciation from plant, patents, etc., the large sum of £3,762. 0s. 3d. (exceeding by nearly £900 the liberal amount written off last half-year), the balance to the credit of profit and loss account for the half-year is £10,614 2s. 7d. Out of this the directors propose that dividends be paid at the full rate of 6 per cent. per annum upon the preference shares, and at 7 per cent. per annum (as before) upon the ordinary shares, together amounting to £6 586 5s. 2d. The amount payable to the directors, in accordance with the articles of association, is £1 208 7s. 3d., and it is proposed to carry £2,500 to the reserve fund, raising the latter to £5,146. 9s. 11d. The balance, £319. 10s 2d., it is proposed to carry forward. Arrangements for the manufacture of the Willans engine upon the Continent, under license, have made further progress. "Royalties receivable" appear for the first time in the accounts, and this source of revenue is likely to increase. Licenses for certain countries have been granted upon satisfactory royalty rates, and in connection with these licenses certain sums down have also been received. After writing off all expenditure incurred in arranging the licenses, the sum of £3,632 12s 1d. remains to the credit of profit and loss, enabling the directors, as already stated, to write off about £900 as increased depreciation, and to reserve an equal amount in the valuing of other accounts. They are also able to carry an unusually large sum to the reserve fund. The balance of the shares authorised to be issued (to which the attention of shareholders was called by circular, dated June 1 last) has been taken up The applications for shares considerably exceeded the number to be allotted. The entire debenture debt, amounting to £9,910, was paid off as from March 31 last. Many of the debenture-holders applied for and were allotted shares in lieu of the cancelled debentures It was thought desirable to perpetuate as nearly as might be the system of workmen's debentures, which has been for some years in force, and workmen's bonds, to the amount of £1,080, were issued to the holders of cancelled workmen's debentures, bearing the same interest as the latter. The increase under salaries is chiefly due to a change in the mode of paying certain officers of the Company, by which they appear in the salary list instead of in the wages list. The change has no effect upon the final result. The new works at Rugby make satisfactory progress, though they cannot commence to add much, if anything, to the out-turn from the Company's workshops for another six months. Up to the present time contracts for buildings, etc., have been placed to the amount of about £18,700.

Reuter's Telegram Company, Limited.—The directors have declared an interim dividend at the rate of 5 per cent. per annum, tax free, for the half-year ended June 30.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Tongres.—The Municipal Authorities of Tongres (Belgium) invite tenders by October 12, 1895, for the concession for the installation and working of the electric light in the town.

Brussels.—Tenders are invited by October 16 for the supply of telegraph cables and copper wire in two lots, for the Administration of Telegraphs. Particulars at the Administration des Chemins de fer, des Postes, et des Télégraphes, Brussels.

Paris.—Tenders are invited for the supply of electric cables, in two lots, for the Administration des Postes et des Télégraphes. Particulars are obtainable of the Administration, 103, Rue de Grenelle, Paris, where tenders are to be sent by October 10.

Madrid.—The Director of Public Works invites tenders by November 15 for the concessions of the construction and working of a tramway from Madrid to Colmevar Viejo, with branches to Chamartin and Rosa. Security, 12,505 pesetas. Particulars at the Direccion General de Obras Publicas (Ministerio de Fomento), Madrid.

Bedford.—The Electric Lighting Committee invite tenders for the supply and delivery of 200 cast-iron lamp columns, carriers, and globes, in accordance with plans and specifications, a copy of which can be obtained at the office of Mr. T. S. Porter, clerk, Town Hall, Bedford, on payment of a fee of 5s. Tenders, marked "Electricity," must be delivered to the clerk by October 8.

London, E.C.—The Bengal and North-Western Railway Company, Limited, are prepared to receive tenders by October 16 for the supply of 22 copper tube plates. Specifications, with form of tender and general conditions of contract, may be obtained at the company's offices, 237, Gresham House, Old Broad-street, E.C., upon payment of 10s. each. Tenders must be addressed to Mr. E. L. Marryat, secretary.

Edinburgh.—The Lord Provost, Magistrates, and Council invite tenders for the wiring of the Waverley Market. Specifications and forms of tender can be obtained at the resident electrical engineer's office, 5, Dewar-place, Edinburgh. A deposit of £1 is required, which will be returned on receipt of bona fide tender. Tenders are to be sent to Mr. Thomas Hunter, W.S., town clerk, City Chambers, Edinburgh, endorsed "Tender for Wiring Waverley Market," before 10 a.m. on 12th inst.

Newport.—The Corporation of Newport are prepared to receive tenders by October 11 for wiring and for supplying and fixing electrical fittings at the provision market and public baths, Newport. Copies of plans and specification may be obtained upon application to Mr. R. H. Haynes, borough engineer, Newport, upon payment of £2. 2s. Tenders, endorsed "Market and Baths Wiring," to Mr. Albert A. Newman, town clerk, Town Hall, Newport.

Chepping Wycombe (Bucks.).—The Urban Sanitary Authority for this borough are prepared to receive tenders from public companies for working the electric order obtained by them within the borough for a term of years and upon approved conditions. Tenders are to be delivered by noon on October 14 next, at the office of the town clerk, High Wycombe, where a copy of the electric order may be seen and further particulars obtained. The Authority do not bind themselves to accept any tender.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

Croydon.—The Council are prepared to receive tenders for wiring and for supplying and fixing electrical fittings at the New Town Hall, Courts, and Free Library. Copies of the specification may be obtained upon application to the architect, Mr. Charles Henman, A.R.I.B.A., 64, Cannon street, London, accompanied by a deposit of £2. 2s., which will be returned on receipt of a bona fide tender. Plans of the lighting system may be seen at the architect's office, as above, and at the New Town Hall, Croydon. Tenders to be sent to Mr. C. M. Elborough, town clerk, by October 8.

Blackburn.—The Corporation of Blackburn invite tenders for the following: Contract No. 1.—High-tension concentric cables, low-tension triple concentric cables, cast-iron pipes, junction-boxes, drawing in boxes, service-boxes, etc. Specification, conditions of contract, and forms of tender may be obtained at the offices of Mr. E. M. Lacey, 10, Delahay-street, Westminster, on and after September 23, on payment of £1. 1s., which will be returned on receipt of a bona fide tender. Tenders, sealed and endorsed "Electricity Extensions," must be delivered at the Town Hall, Blackburn, on or before October 5.

London, W.—The Great Western Railway Company desire tenders, among other stores, for the supply of telegraph instruments, telegraph apparatus, copper wire, G.P. wire, etc., telegraph ironwork and tools, telegraph drysalteries, carbons for electric light, iron wire, acids, alkalies, zinc, telegraph poles, from November 1, 1895, to October 31, 1896. Samples and patterns may be seen on and after 23rd inst. at the office of the stores superintendent, Paddington Station. Specifications, with forms of tender, may be obtained at the office of the stores superintendent at Swindon or Paddington Stations. Tenders, addressed to Mr. G. K. Mills, secretary, Paddington Station, London, and marked outside "Tender for Stores," will be received on or before October 7.

Dundalk.—The Dundalk Town Commissioners invite tenders for erection of an electric lighting installation for the purpose of lighting the town by electricity on or about July 1, 1896, reserving to themselves the right of taking over the plant at the end of a term of years—this term to be stated in the tenders. The successful contractor to have the right of supplying private consumers, while the Commissioners will pay a fixed sum yearly for the town lighting—this sum to be stated in the tender also. The Commissioners have obtained a license from the Board of Trade for supplying electric lighting. Tenders will be received by Mr. Edward Farrar, town clerk, Town Hall, Dundalk, up to October 7.

RESULTS OF TENDERS.

Kingston-on-Thames.—The following tender has been accepted for the supply of coal for the electric lighting works, for the Town Council: T. Styles, Durham rough, small, 11s. 6d., Hartley rough, small, 9s. 9d., and Welsh nuts, screened, 16s. 9d. per ton.

Lincoln.—The following were the tenders for the new chemical laboratory at the School of Science and Art. Mr. W. Watkins, F.R.I.B.A., Lincoln, architect:

M. Otter and Co.	£231
W. Wright and Son	225
A. B. Wright (accepted)	207

BUSINESS NOTES.

Belfast.—It is proposed to light the Belfast Lunatic Asylum by electricity.

Rand Central Electric Works, Limited.—The directors have made a call of 5s. per share.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3 249.

Aberdeen.—The electrical installations at the new police station have been carried out by Messrs. Shirras, Laing, and Co.

Stafford.—The formal opening of the electric lighting works is to take place on the 15th inst., but the current will be switched on for a few days previously for testing purposes.

Eastern Extension, Australasia, and China Telegraph Company, Limited.—The directors have declared an interim dividend for the quarter ended June 30 of 2s 6d. per share, tax free.

Wimbledon.—The Ratepayers' Association have decided to convene a public meeting on October 8 to take into consideration the scheme of electric lighting adopted by the District Council.

The Safety Tread Syndicate, Limited (Mason's Patent), have been appointed contractors to H.M. War Office, the Admiralty, and the India Office for the supply of their well-known safety treads.

East Grinstead (Sussex).—The Urban District Council, who are somewhat dissatisfied with their gas supply, have appointed a committee to meet Messrs. Owen and Pike on the subject of the electric light.

Globe Telegraph and Trust Company, Limited.—The directors have declared an interim dividend of 3s. on the preference shares, less income tax, and of 1s. 3d. on the ordinary shares, income tax already deducted.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 29th ult. amounted to £1,266, as compared with £988 in the corresponding week of last year, being an increase of £278.

Direct United States Cable Company, Limited.—The Board have resolved upon the payment of an interim dividend of 2s. per share, free of income tax, being at the rate of 2 per cent. per annum for the quarter ended September 30.

Isle of Man Tramways and Electric Power Company, Limited. The directors have declared an interim dividend for the six months ending June 30 at the rate of 6 per cent. per annum on the preference shares, and at the rate of 7½ per cent. on the ordinary shares.

Drake and Gorham.—This firm have just had placed with them the contract for the electric lighting by means of a separate plant of The Lea, Esher, for Mr. C. C. Wyllie. In London they are proceeding with the wiring of Major the Hon. E. R. Bourke's house at Great Cumberland-place.

Bearpark (Durham).—The Parish Council have considered the question of lighting the parish, when it was resolved that the question of lighting stand over until the Council meet a representative of the owners of Bearpark Colliery, with a view of ascertaining the probable cost of the electric light.

Londonderry.—Alderman Fleming said, at the meeting of the Lighting Committee of the Corporation, that he quite agreed with Alderman Pollock that the electric light was needed in the churches, as the gas lighting was very bad. He hoped the chairman would soon call a meeting to consider this matter.

City and South London Railway.—The returns for the week ended September 29 were £823, compared with £881 for the corresponding period of 1894, being a decrease of £58. The total receipts for the half-year 1895 are £10,971, compared with £11,119 for the corresponding period of 1894, being a decrease of £148.

Peterborough.—The borough engineer has reported to the Town Council on the scheme for electric lighting proposed by him in consultation with Dr. Fleming, and recommended that applica-

Digitized by Google

tion be made to the Local Government Board for sanction to borrow £20,000 for the proposed works. The report was referred back for the engineer to reconsider and revise

Universal Electric Carriage Syndicate, Limited.—This Company has been registered with a capital of £5,000 in £1 shares. Object: to enter into an agreement with W. C. Bersey, and to carry on the business of electricians, electrical engineers, etc., in all its branches. The directors are D. B. Miller, R. J. Hinton, C. N. Stewart, and (after allotment) W. C. Bersey (managing director).

Agency.—Mr. D. J. Russell Duncan, formerly senior partner in the firm of Messrs. Duncan Bros., engineers, Westminster, and late managing director of the Steel Pipe Company, Limited, has commenced business at 80, Boulevard Haussmann, Paris, as agent for the sale of machinery, electrical apparatus, and specialities of British manufacture suitable for French trade, also for the sale of inventions protected in France.

Bermondsey.—The Vestry have received notification from the Capital and Counties Electricity Supply Company, Limited, of their intention to apply, on or before December 21 next, by memorial to the Board of Trade, for a provisional order, authorising the company to supply electricity for public and private purposes within the area of the jurisdiction of the Vestry. The matter was referred to committee.

Lithanode Electric Storage Company, Limited.—This Company was registered on September 23, with a capital of £12,000, in £1 shares. Objects: to acquire the business carried on by the Lithanode and General Electric Lighting Company, Limited, Millbank-street, Westminster, to enter into agreements with the said Company and its liquidator, and to carry on business as electricians and electrical engineers in all its branches.

Jean Concessions Guiana Rubber Company, Limited.—This Company has been registered with a capital of £100,000 in £1 shares. Object: to adopt and carry into effect an agreement, made September 4, between Joseph M. Jean of the one part and Jn. A. Russell, on behalf of this Company, of the other part, and to carry on business as rubber-tree growers and merchants, timber growers, farmers, indiarubber manufacturers and merchants, etc.

Marine Cable for Japan.—The Japanese Government have ordered 800 miles of submarine cable from the Telegraph Construction and Maintenance Company, this, it is understood, being intended for effecting telegraphic communication between Japan and Formosa. It is stated that the Japanese have determined to lay this cable themselves, and that they are having a cable ship built in this country, so that they will soon be in a position to lay and repair their own cables.

Important Belgian Enterprise.—On September 25, as already advised, the Société générale belge d'entreprises électriques was constituted at Brussels with a capital of 6,000,000f., which may be increased to 10,000,000f. Interested in the undertaking are the Société générale des chemins de fer économiques, Compagnie générale des chemins de fer secondaires, Banque de Bruxelles, Banque de Paris et des Pays-Bas—all of Brussels; further, the Comptoir National d'Escompte de Paris and the Gesellschaft für elektrische Unternehmungen (Union), of Berlin.

Chelmsford.—The Chelmsford Electric Lighting Company have written to the Town Council regretting that on two nights recently there was a failure in the street incandescent electric lighting supply. In order to meet the wishes of the Council and abate a smoke nuisance which had been complained of, the company had been engaged in fitting their boilers with patent smokeless furnaces, but in doing this they had found that their reserve boiler power was insufficient to keep the lights going. There was now every reason to believe that no further inconvenience would accrue.

Blackpool.—The other day two transformer-lids were blown off. It is supposed that sparks ignited the gas which had collected in the chambers. Councillor Pearson, at the last meeting of the Town Council said that it was pleasing to note that the electrical works were going on from success to success, and financially they were reaping large results week by week. With respect to the tramway, he reported that the Board of Trade had granted the license to work the Lytham-road section. The committee put it into force forthwith, and the electrical cars were working to South Shore station.

Appointment Vacant.—The Dundalk Town Commissioners will at their meeting on October 29 appoint an electrical engineer for reporting on the cost and the best means for lighting the town by electricity, and also to assist the solicitor in obtaining a provisional order from the Board of Trade granting power to the Board to erect works and plant to supply electricity within the borough Applicants will be required to state a bulk sum, if possible, which will cover all fees and expenses incidental to the work they propose to undertake. Applications to be sent in to Mr. Edward Ferrar, town clerk, Town Hall, Dundalk.

The Imperial Western Australian Corporation, Limited, with a capital of £500,000 in £1 shares, of which 5,000 are deferred shares, has been formed for the purpose of conducting the business usually carried on by an exploration and finance corporation; to prospect, acquire, develop, and otherwise deal with mining and other properties in the colony of Western Australia and elsewhere; to promote sub-companies; to purchase, lease, or work such properties; to purchase, resell, sub-divide, lease, or otherwise deal with lands (including town sites); to obtain concessions for and construct railways, tramways, electric lighting, harbour, and other works in the colony of Western Australia, etc.

Swansea.—The negotiations which have been carried on by the Swansea Corporation and the proprietors of the tramways for the purchase of the latter have not yet reached a definite point. Two years' time is still left for the municipal authorities to make up their minds what to do. The tramway company, in the event of another lease of 31 years being granted, will, we understand, undertake to relay the lines throughout and give an improved service by means of electrical power. It is stated that the directors have already determined upon using electrical power instead of horses, and that as soon as a definite arrangement is made with the Corporation the necessary electrical plant will be secured.

Liverpool.—On the motion of Alderman F. Smith, seconded by Mr. Brownbill, the following recommendation of the Special Lighting Committee of the Corporation has been agreed to: "That, in accordance with the agreement, dated May 28, 1895, between the Liverpool Electric Supply Company, Limited, of the one part, and the Corporation of the other part, a further agreement be made by the Corporation with the company to complete the purchase of the company's undertaking, works, and property in accordance with the before-mentioned agreement within six weeks from the date of an Act of Parliament authorising the sale to the Corporation, provided such Act is passed in the year 1896, and that the seal of the Corporation be affixed to such agreement."

Halifax.—The Tramways Committee's report to the Town Council contains details and plans and estimates for an overhead tramway system given by Messrs. Easton, Anderson, and Goolden, Limited, who are prepared to construct and lease the lines. Two routes are suggested—one from the railway station by Horton-street and Commercial-street to King Cross, and the other from the Grand Theatre to Haley-hill and Boothtown. The cost to the Corporation of the roadwork is estimated at £12,500 for the 3½ miles, and the firm's rough estimate for erecting and equipping an overhead electrical system service is about £18,500. At Wednesday's Council meeting it was decided that the matter be referred to the new November Council.

New Arc Lamp.—The arc lamp is now displacing to a great extent in lecture illustrations the oxy-hydrogen light, which was itself a great advance upon the old oil-lamp form. Improvements in the first-named were shown last week at the Camera Club. They have been patented by Mr. Cecil M. Hepworth, and the apparatus is known as the Ross-Hepworth arc lamp. The design is said to be simple and possess all the means necessary for keeping the light spot central with the lens. The light itself is steady, and the brilliance may be regulated according to requirement. The most novel feature is the device by which the arc can be struck instantaneously, and arrangements, we are informed, are being made to test its usefulness in this respect for naval searchlight purposes. The lamp is manufactured by Messrs. Ross and Co, opticians, Bond-street, W.

Telephones in Germany.—The telephone exchange at Essen, the town famous for Krupp's gun factory, was last week fitted up with multiple switchboards (for 6,000 subscribers) which have been manufactured and erected by Messrs. Mix and Genest, Limited, of Berlin, for the German General Post Office. We read in the local paper that the telephone service has thereby been greatly benefited, as the attention is more prompt, and less noise is noticeable at the exchange, the previously stereotype enquiries, "Have you finished?" not being needed with these patent multiple switchboards, as testing is done by galvanometers. The neighbouring towns of Dortmund, Bochum, etc, had previously been fitted with multiple switchboards of the same system and manufacture, where the working of the same had given great satisfaction, thereby accelerating the transformation of the old exchange at Essen into one equipped with the most modern apparatus.

Holophane Globes.—An exhibition was given in the showrooms of the Liverpool Gas Fittings Company the other day of a "new discovery in lighting which increases the amount of light obtainable by all systems of illumination, whether gas, oil, or electricity." It is stated that a company is about to be formed to purchase the patent rights of the invention for all countries except Great Britain and Ireland of Messrs. Blondel and Psaroudaki for the manufacture of Holophane globes, which it is asserted have been used with success in Paris for some months. Among the advantages claimed for the new globe are that it is grooved vertically inside in order to diffuse the light, and grooved horizontally outside in order to distribute the light; moreover, it gives such a perfect diffusion of light that the gain in the power of illumination is said to reach 13 per cent., whereas the loss of light by use of the ordinary shades ranges from 10 to more than 50 per cent. The globes were illustrated in our issue of April 19, p. 449.

Douglas.—The Finance Committee of the Douglas Town Commissioners have advanced a stage the projected cable tramway to Upper Douglas. The draft of the Bill was laid before the committee and considered, also the agreement between the tramway company and the Commissioners. Several enterprising tramway schemes are under consideration in the island, including the extension of the electric tramway to Ramsey, and the extension of the Snaefell railway to Tholt-e-Will by the back of Penny Point Mountain to Ingebrack, and thence to Douglas by Baldwin and Kirk Braddan. A company is in process of formation at Douglas for the purpose of constructing and working an electric tramway along Douglas Head Marine Drive. The Drive is nearly three miles long. In return for the concession of constructing and working a system of trams the new company agree to pay the Marine Drive Company one penny for each passenger conveyed. It is stated that the Douglas and Laxey Electric Tramway Company at the north of Douglas Bay have carried 30,000 passengers in one week. Major Goldie Taubman, Speaker of the House of Keys, is chairman of the new company.

Digitized by Google

St. Pancras.—The Vestry discussed at their last meeting the question of lighting some of the streets of the parish by incandescent gas. Mr. Hodgson said that after a considerable period they were lighting four miles of streets in St. Pancras by electricity at a cost of £6,000. If they multiplied that sum by 21—the number of miles of streets in the parish—they would see what it would cost to light the whole of the borough. A proposal made that a letter respecting the lighting of the streets by incandescent gas should be simply acknowledged was eventually carried. The electricity works at the King's-road station are now practically completed, and as soon as the work of connecting is finished the supply will be turned on. Most of the destructor furnaces have been lighted for some few weeks for a few preliminary tests, and have been found to be generally satisfactory, but few small modifications having been necessary to suit the character of the material delivered. The Hearts of Oak Society have at last overcome the scruples of the Vestry, for by 40 to 6 it has been decided to give the society permission to have a service pipe laid from the Hydraulic Company's mains on condition that the power is used for no other purpose than for a lift, the Vestry being desirous of protecting themselves against any possible use of the power for the manufacture of electricity.

Berkhamsted. — The chairman of the Great Berkhamsted District Council has received the following letter: "Bedford Electric Light Company, Limited, 3, St. Paul's-square, Bedford, September 13, 1895.—Sir,—As far as I am aware, no action has been taken by your Council with regard to the notice of the proposed application by this company to the Board of Trade under the Electric Lighting Acts, 1882 and 1888, for a provisional order to authorise the introduction of the electric light at Berkhamsted. I am now instructed by my directors to open negotiations with your Council with a view to obtaining their consent to the proposed application by this company. In making this application my directors do not think it desirable to suggest any terms upon which they are willing to undertake the lighting; but if your Council entertain the application to leave them to grant to them their consent upon such conditions as they consider desirable in the interest of the neighbourhood to be lighted and fair to the undertakers. My directors, however, wish me to inform you that they are prepared to meet the views of your Council in every way they possibly can —Your obedient servant, W. Jessop, secretary. F. Q. Lane, Esq." No action was taken by reason of no specific application being placed before the Council, but it was agreed that there was no objection to the electric light company applying to the Board of Trade in the matter as it referred to the roads.

Sunbury-on-Thames.—The District Council have received a report from Mr. Anstie, engineer to the Council, with reference to the suggested scheme of sewage pumping by electricity, the scheme having been patented by Mr. H. South. The report dealt with each detail supplied by Mr. South, and Mr. Anstie pointed out that whereas the electrical machinery was estimated to cost £5,000, against Mr. Anstie's scheme, £7,860, there were several omissions in the former estimate which it was calculated would increase it to £6,244. The annual outlay in connection with the electrical scheme would, it was stated, prove as expensive as the ejector scheme, and Mr. Anstie questioned whether the Council were justified in trying the experiment in such an important district. He further gave his opinion that the Local Government Board would not sanction the expenditure on the electric scheme in lieu of the one they had already sanctioned. The clerk read a further letter received from the Local Government Board acknowledging the Council's reply, and asking upon what points they had asked the engineer to report. The Board wished also to know what steps the Council had taken to acquire land in regard to the sewerage scheme, and desired an immediate answer. It was eventually agreed that the clerk should reply that pending the report of the engineer no steps had been taken, and send Mr. South a copy of the report, and that it should be further considered at the next meeting.

Leicester.—Councillor Clarke read at the last meeting of the Town Council a memorial from the electrical engineers of the town asking the Council to seriously consider the action of the Electric Lighting Committee in connection with the trade of fitting electric light installations. The Corporation, they stated, had created a competition between themselves and the petitioners which threatened to overwhelm their trade as contractors, and was stifling that healthy competition between local electricians which would otherwise exist for the benefit of the public. They therefore prayed that the committee might be instructed to refrain from competing with the local trade in fitting electric light installations. He moved that the petition be referred to the committee. Alderman Sir Thomas Wright seconded, and it was agreed to. In moving the adoption of the electric light report. Alderman Lennard said the income had been £963, including £268 for the fittings business. The expenditure, apart from interest and sinking fund, was £863, showing a profit of £100 on the revenue account, although it was not till late in the winter season that they got to work with it. But after deducting the interest and sinking fund there was a balance of £951 on the wrong side for the half-year. That was a large amount, but he would prophesy that when he made his next half-yearly report the balance-sheet would be pretty well even after paying the sinking fund. The actual loss on working now was only about £400, £700 of the total deficiency being on account of sinking fund.

Edinburgh.—The Cleaning and Lighting Committee of the Town Council have agreed to recommend that the West Bow and the Grassmarket should be lighted by electricity, and also to erect electric lamps at the corners of Picardy-place and London-road. The committee further recommended that until some definite scheme of extension is resolved upon, the request of the proprietors in Castle-terrace for the lighting of that thoroughfare by electricity should not be entertained. The Edinburgh Electric Lighting Committee decided on Tuesday upon the Brockie-Pell electric lamp for the lighting of Charlotte-square, George-street, St. Andrew-square, and the streets leading up to them from Princes-street. It appears that the former contractors could not undertake to supply the present style of lamp at the old price. The committee had likewise under consideration the matter of the frequency with which breakages of public electric lamp globes are brought to the notice of the staff. It seems that of late breakages have been reported so often that the suspicion is entertained that they are not caused by legitimate wear-and-tear, but are the result of wilful mischief on the part of persons using catapults. As these electric light globes are specially manufactured in Austria, and cost about 9s each, the matter is regarded by the committee as by no means a trifling one. As the result of the meeting, instructions were given to the police to take special precautions to detect and punish offenders The hope was further expressed that the public would assist the authorities in the matter by preventing or reporting cases of wilful damage.

Bedford —A correspondent writes: That the action of the Town Council with regard to the institution of the electric light in Bedford was the right one, has been satisfactorily proved by the ever-increasing demand which is being made upon the resources of the electric light station. Although the long evenings and short days are not yet upon us, it has been found necessary to increase the power of supply, and considerable alterations are now in progress at the central station at the Caldwell Bridge. When the building was planned and erected about a year ago the possibility of extension had to be considered, and it was arranged that the building should be blocked at either end with temporary walls so that at the proper time additions could be easily made The two new alternators are of much larger and much more powerful design by Messrs. Siemens Bros., though the type is similar to those at present in use. A substantial bed of concrete is being prepared for their erection. and it is expected that when they are in working order they will be able to manage three times the load which taxes their resources. There will be room for a third if it is required. The boiler-room, situated on the side nearer the river, is also being greatly enlarged, and new Scotch furnaces are in course of erection The additions have added much to the appearance and importance of the electric light station and it is expected that the additional power will enable them to meet all the demands made upon the light during the coming winter at least. The electric light has found excellent customers amongst the principal shops of the town. The Corn Exchange uses about twice as much as the Town Hall, and now that several of the clubs of the town have been connected there is a considerable increase in the consumption. The extension of the mains in the Cardington-road district has resulted in a call from many private residents, while something may be expected from Midland road, where work is in progress.

St. Helens.—Mr. F. H. Tulloch, an inspector to the Local Government Board, held an enquiry at the St. Helens Town Hall, on Tuesday, on the application of the Corporation to borrow £10,000 for the purpose of the electric lighting of the main streets in the centre of the town. The case of the Corporation was laid before the inspector by Mr. W. J. Jeeves (town clerk), who said the Corporation owned the gas undertaking, and had therefore a special interest in keeping control over the electric lighting. In former years there had been applications by various companies for provisional orders authorising them to supply electricity within the borough, which had been consistently opposed by the Corporation, as they felt that they ought to have control themselves, and believed the time had not come for the installation of the light. In 1894 they considered that they ought to have power to put down an installation, and they, therefore, applied for a provisional order, which was granted, and it was under the provisions of that order that the application was being made. They proposed to put down an installation at the gasworks, and from there lay a cable through Corporation-street to the corner of Hardshaw-street, where a new technical school and free library was being erected, which would require to be lighted with electricity. The plant the Corporation were putting down would be sufficient to light the public buildings referred to and to supply any demands for electric lighting likely to be made within the immediate future, and it was to be so arranged that while sufficient for present purposes, it would be capable of extension should demands warrant it. In reply to the Inspector, the Town Clerk further stated that the contracts for the plant had been let subject to the approval of the Local Government Board. Mr. Peter M'Kinley, a town councillor, said he was not altogether opposed to the electric lighting, but he protested against contracts being given out before the consent of the Local Government Board had been obtained. There had been a lot of trouble about the same thing in years gone by, and the Corporation gave an undertaking to the inspector that they would not do it again. The Inspector replied that the contracts on the present occasion were let subject to the approval of the Board, and were not accepted or given out in the ordinary meaning of those words.

Yeadon.—The property owners and ratepayers of Yeadon have met in order to consider the following resolution: "That the Yeadon Urban District Council adopt the electric light for the purpose of lighting the district as provided in the provisional order obtained for same." Mr. Medhurst, electrical engineer, of London, who has been called in by the District Council to advise on the tenders sent in, said he recommended the Council to accept the tender and scheme of the Brush Company. This

Digitized by Google

amounted to £5,487, but the tender did not include buildings, foundations, connections with the consumers' premises, excavating and making the roads good again, sundry charges, contingencies, etc., which he had estimated at £1,795, thus bringing the total cost up to £7,282 The plant was to be equal to supplying 1 800 lamps, besides 146 street lamps, and although the undertaking would not quite pay interest and sinking fund during the first and second years, he believed that in subsequent years there would be a surplus. The charge proposed to be made was 10s. per lamp per year. A number of questions having been asked and answered, addresses were given by several numbers of the Council. Messrs. J. Flaxington, H. Marshall, and Tony Marshall spoke in favour of the Council adopting the light, the two former giving a number of statistics in support of their contention that the undertaking could be made a paying concern. On the other hand, Messrs. Hudson (chairman of the Council), Cooper, Jenkinson, and Bolton condemned the proposal, holding that it would be a burden on the rates. Mr. Jonathan Peate said that if the Council were expecting to light the mills with the electric light he was afraid they would find themselves mistaken, as the mills, having their own power, could produce the light on terms far more advantageous than could be given to them by the Council. He did not therefore see how in a scattered place like Yeadon they were going to get 1,800 lamps. He was not against the adoption of the electric light at some future time, but he argued in favour of delay. A resolution having been proposed and seconded that the Council adopt the light, Mr. Peate moved an amendment that the question be deferred for three months, and that in the meantime the District Council ascertain what number of lamps they could get taken up. The amendment was carried.

Copper.—More than usual interest attaches to the latest monthly statistics of the copper trade, says the *Financial News*, owing to the fresh batch of rumours with regard to the proposed arrangement for regulating supplies, and to the active demand for copper shares to which the rumours have led. For more than a twelvemonth past there has been much talk about the intentions of the producing companies and from time to time it has seemed as if the negotiations were on the point of being concluded; but so far, nothing has been settled, though there are many who believe that the latest proposals for a restrictive combination, with the Rio Tinto and Anaconda companies at its head, will shortly be generally accepted. That it would be possible for the principal producing companies to reduce the supplies of the metal, and thus, for a time, at least, to lift the market values both of copper and copper shares, is indisputable; but arrangements for tinkering with the natural laws of supply and demand, however apparently safe and profitable to those who join in them, have a very awkward knack of going wrong, as the experience obtained by the Société des Métaux in 1888 showed very plainly Of course, it will be said that the projected combination is of quite a different character, and that producers have no desire to raise prices unduly, or to bring about anything approaching a corner. With the beginnings of industrial revival in many directions, it is clearly desirable that consumption should be encouraged as much as possible, seeing that the greater the demand the more certain, if gradual, would be the improvement in the value of the commodity. To force up prices by artificial manipulation would inevitably check the demand, and it is obviously better to be able to sell an article freely at £47 per ton than to have it left on one's hands by asking £60 or £70 per ton for it. This being so, it seems to us self-evident that the copper producing companies would act wisely in adopting the policy of *laissez faire*. The consumption of copper is increasing satisfactorily, and it will continue to do so if it be left to take its natural course. That the deliveries of the metal have already got ahead of the supplies is proved by the monthly statistics which have just been issued by the leading firms From the figures furnished by Messrs. Henry R. Merton and Co. it would seem that the total supplies of copper in England and France last month amounted to 8,361 tons, and the deliveries in England and France were 10,950 tons.

South Staffordshire Tramways.—Correspondence between the South Staffordshire Tramway Company and the Board of Trade, on the former's application for the renewal of the license to use steam on their tramway, has been read before the Tipton Urban District Council. The tramway company, in their letter, regretted that the agreement with the Electric Construction Company had not been finally concluded, but they hoped it would be shortly. The portion of the tramway which passed through Tipton barely paid working expenses in the summer time, and in the winter was a source of considerable loss, and, therefore, to some extent increased the difficulties which they would have to surmount in providing an improved mode of traction for the other and more profitable sections of the tramways. Several of the engines had been thoroughly overhauled, in order that they might make less noise and be more safe. That, however, would not impede their progress towards providing an improved mode of traction. A letter from the Board of Trade stated that they were unable to regard as satisfactory the circumstances under which the application was made. They had frequently renewed their consent to the use of steam power on the tramways, notwithstanding the objections of certain of the local and road authorities, in the hope and on the assurance that within a reasonable period an improved system of traction would be introduced. The company had, however, made little progress in this direction. In these circumstances the Board of Trade had had serious doubts whether they were justified in granting any further extension of the authority to use steam power, but having regard to the consensus of local opinion referred to in Major Marindin's report of January 31 last that it would be detrimental to the interests of the public if the tramways cease to be worked, they had decided to give a final opportunity to the company of establishing a proper system of traction, and thereby avoiding the contingency referred to. Authority to use steam power would be given until the end of the year, but no application for a further extension would be considered unless either the company were able to satisfy the Board of Trade that arrangements for improved traction were actually in progress, or the local and road authorities supported the application, giving adequate reasons for their support. The Chairman said he should like to know if the tramway company could not possibly, at the end of the year, adopt another form of traction, and their only alternative would be to stop running, whether the Council would sanction the closing of the tramway or not. Councillor Doughty said Walsall, Wednesbury, West Bromwich, and Dudley would be sure to be in favour of continuing the trams, because they took people into these towns for business purposes. Tipton was not so favourably situated—in fact, the people went out of Tipton. He objected to overhead wires as being more dangerous than the steam-engines. He was in favour of the cable. Councillor T. H Millington said he had heard of complaints from Tipton people of the trams taking the money out of the parish, and there were those who would hail with delight the entire stoppage of the trams. Councillor Doughty proposed that the Council, at the end of the year, oppose the running of the steam-engines under any circumstances. Councillor Earp thought they should not be too eager to take action against the company. If the Tipton shopkeepers could not compete with shopkeepers in other towns, and so keep the people at home, they had better shut up. The cable system would be useless at Ocker Hill. They allowed the canal company to raise bridges, but because the tramway company was a weak one they tried to put their foot on it. The Chairman objected to that. The steps they had taken were in the interests and for the safety of the public. He thought they had been very patient with the company. Councillor Butler was of opinion that overhead wires were worse than steam-engines. Councillor Round: Those who drive would sooner meet a steam tram than pass the overhead wires. Councillor Walker proposed that if they were unable to get the cable tramway they should favour the existing steam trams. Councillor Earp: I should like to know what it has cost the tramway company in law expenses. Ultimately it was decided to object to the running of the steam trams at the end of the year.

NOTES.

Guatemalan Telegraphs.—A statement just published shows that Guatemala has 409,769dol. invested in Government telegraph wires, and employs 469 operators.

North-East Coast Institution.—A conversazione in connection with the North-East Coast Institution of Engineers and Shipbuilders will be held at the Assembly Rooms, Westgate-road, Newcastle, on October 18, at 7.30 p.m.

Non-magnetic Metal.—*L'Eclairage Electrique* says that steel containing 12 per cent. of manganese is not magnetic, and that therefore this property could be utilised with advantage in the construction of many electrical apparatus.

Threshing Grain by Electric Transmission of Power is at present being carried on with very satisfactory results at Mjölby, in Sweden. The electricity is conveyed a considerable distance from the main cable to a motor in the immediate vicinity of the thresher.

Electricity in Russia.—The Russian Government has established in Lugansk, in the province of Ekaterinenburg, a cartridge factory, with an annual capacity of 100 million small-bore cartridges. It is stated that 1,000 men are employed at the works, in which electricity is used as motive power.

Incandescent Lamps and Eyesight. — Dr. Gebhardt, of Budapest, has raised an emphatic protest against the practice of putting electric incandescent lamps at a low level among the wares in shop windows. He says this is exceedingly destructive to the eyes, and that these lamps should always be put out of the direct range of vision.

Traction Trials in Berlin.—The *Elektrotechnischer Anzeiger* (October 6) announces that the municipal authorities of Berlin have resolved to grant a credit of 50,000 marks (£2,500) for the purpose of carrying out experiments with various forms of traction, more particularly with the Serpollet steam car, the Dessau gas car, and the improved accumulator systems.

The Tesla Patents.—MM. Schneider and Co., of Creuzot, who alone hold in France the Tesla patents for electromotors with rotary field, have taken proceedings against MM. Weyher and Richemond, who make the Brown motors; MM. Guitton and Bertolus, who manufacture the Oerlikon motors; M. Joly, the representative of M. Alioth; and the Société Grenobloise, for alleged infringement of patents. In Germany, the Actiengesellschaft Helios of Cologne possesses the Tesla rights, and it has acted in a similar manner.

Electricity as an Aid to Navigation. — The inland steamer companies in Calcutta acknowledge the utility of the electric light as an aid to navigation. Several vessels of both leading companies have already been fitted with installations, and the Rivers Steam Navigation Company is having others of its boats electrically equipped this season in order to contend with the expected heavy jute business. These steamers will then be able to run at night and do the distance between Naraingunge and Calcutta in about four days, whereas the trip ordinarily occupies from eight to ten days.

Royalty and the Electric Light.—The other week an alarming report was circulated, only to be immediately contradicted, as to the abhorrence in which Queen Victoria held the electric light. Now we are informed, doubtless on equally reliable authority, that the Empress of Austria has "a positive horror" of the same illuminant—indeed, of gas also—inasmuch as she "forbids the use of anything but the purest wax to light up the palace; and it is," we are told, "very amusing to see the servants, to whom the half-burned candles belong by right, make a rush to blow them out the moment the last guest has walked out of the rooms."

The Institution of Junior Engineers.—At the annual general meeting of this institution at the Westminster Palace Hotel it was stated that the membership roll had increased by 45, the total at the present time being 418. The Belgian summer meeting was, it appears, highly successful. The institution premium for the best paper read by members during the session has been awarded to that on "The Warming of Buildings by Hot Water," of which Mr. E. King and Mr. Kenneth Gray were joint authors. On Thursday, October 17, at 6.30 p.m., a visit will be paid to Messrs. Caird and Rayner's works, 777, Commercial-road, Limehouse, E.

Personal.—The third electrical engineer appointed by the Hull Corporation is Mr. Adam Sedgwick Barnard. Mr. Barnard is 27 years old, and at present is electrical engineer to the Town Council of Lancaster. There he has had entire charge of the electrical supply undertaking, which position he has held since the commencement of the works in 1893. He designed and carried out several extensions of the system, and is now engaged in laying a number of new distributing-mains. Mr. Barnard has been solely responsible for the street electric lighting of Lancaster, as well as for the bulk of the private lighting, which he has carried out with his own staff.

Train and Tram Lighting by Electricity.—Lighting railway carriages by electricity, the *Railway Engineer* says, is to have another trial, and this time with every prospect of success. The London, Tilbury, and Southend Railway Company, after having made extended trials with the system which is being introduced by Messrs. J. Stone and Co., of Deptford, have decided to electrically equip two additional trains. The Midland Company and the Midland Great Western of Ireland are also giving extensive trials to this system. The North Metropolitan Tramways Company, again, are adopting the electric light experimentally, several of their cars on the Aldgate and Stratford route being already fitted with electric lamps.

Nature's Lightning-Rods.—M. Oovaroff, the Russian electrician, of Moscow, and Prof. Hirscht, Government forest inspector, of the same city, have published some investigations concerning the liability to lightning-stroke of certain species of trees. In the summers of 1893 and 1894 the two scientists spent 109 days in the great forests between Moscow and Remereff, and during that time found 597 trees that had recently been struck by lightning. Of the total number of marked trees 302 were found to be white poplar (*populus alba*), this notwithstanding the fact that that species is not nearly so common as a dozen other varieties. On the suggestion of M. Oovaroff, the Russian Government recommend that the peasants should use it as a lightning-conductor.

Electricity in Mining.—At the annual meeting of the South Staffordshire and East Worcestershire Institute of Mining Engineers held at Mason College, Birmingham, Mr. J. H. Cooksey, the newly-elected president, said that it was imperative that the mining engineer should be equipped not only with a practical acquaintance with mining in all its branches, combined with a considerable knowledge of mechanical science, but also—and the necessity for this was daily increasing—with an acquaintance with the principles of the science of electricity. Mr. J. Meachem, jun., read before the gathering a paper upon "The Electric Power Plant at Haden Hill Colliery, Red

Digitized by Google

Hill." He explained that the installation was for the purpose of hauling the coal from the face of the work to the shaft, pumping water, lighting, and ventilating.

An Electric Theory of the Solar System.—M. C. V. Zeuger, professor of astronomy and physics at the Prague Polytechnic School, contributed a paper on this subject at the recent meeting of the Association française pour l'avancement des sciences at Bordeaux. M. Zeuger has been experimenting with a hollow copper sphere suspended in an asymmetric field produced by one, two, or three electromagnetic poles, and finds that the movements of the sphere present an absolute analogy to the motions of the planets. He proposes, therefore, "to replace Newton and Kepler's laws by the law of Gauss." It follows as a consequence of the theory that the periods of revolution of the planets and comets must be a multiple of half the period of rotation of the sun, and a similar law would apply to the revolutions of satellites round their primary, except in so far as they may be affected by perturbations of the sun or other planets.

Books Received.—We have received the third and final supplement to Mr. Henry Sell's "Register of Telegraphic Addresses" for the year, correcting the information supplied to Mr. Sell by the Postmaster-General during the past three months. All the additions and alterations contained in the three supplements of the year and any further corrections and information received from the Post Office during the current three months will, we understand, be incorporated in the new volume for 1896, which will be ready early in January next. The new volume will also contain all the trades and professions, as well as the telegraphic addresses and telephone numbers of the 50,000 largest concerns in the country. In the preface to the supplement will be found some particulars as the extension of telephonic communication between large towns. We have also the programme of the City and Guilds Technical College, Finsbury, Leonard-street, City-road, E.C., session 1895-96.

Manufacture of Chloroform by Electrolysis.—It is highly necessary that chloroform should be absolutely pure, for great as are the services that it has rendered to surgery, there is always the risk that the patient may fail to come to if the chloroform used is not quite pure. M. Raoul Pictet claims to have obtained it in a state of perfect purity by distillation at the low temperatures that he has been able to produce. Electricians, however, are setting up against this purification process a method of manufacture which gives quicker results. A double-headed retort of enamelled iron, heated by steam, and containing two lead electrodes, is filled with a 20 per cent. solution of common salt. The liquid is raised to the boiling point and a stream of acetone is sent in and diffused, the electric current passing at the same time. The chlorine produced by electrolysis reacts on the acetone, and the chloroform obtained is collected by distillation. From 100 parts by weight of acetone, it is stated that 190 parts of absolutely pure chloroform are obtained.

Evaporation in Wet Cells.—A simple method of guarding against evaporation and salt secretions in wet cells is described by Herr Carl T. Fischer in the *Elektrotechnisches Echo*. He remarks that the chief disadvantage of open, wet, house batteries, for example, the Leclanché cells, consists in that, in the first place, the liquid is continually evaporating, and that, in the second place, the salt crystallises on the glass. Hitherto, to obviate these difficulties, tallow or asphalte lacquer has been used to coat the upper sides of the cell inside and outside. Herr Fischer uses, after the cells are filled, an infusion of paraffin oil, which, of course, floats on water, to the depth of one or two centimetres. He says that he has successfully employed this paraffin deposit for three years both with batteries and small accumulators. Paraffin oil is the best substance to use, because it may be exposed for years to the atmosphere without becoming rancid. The oil deposit at once absolutely prevents evaporation, since no air can get to the liquid, and paraffin oil itself does not evaporate. Crystallisation of the salt out of the liquid is also prevented.

Sealing Champagne Bottles Electrically.—In a recent number of *La Nature*, M. A. M. Villon describes a novel method of sealing champagne bottles. The loss and deterioration of champagne due to the escape of gas has long, he says, made some process of perfect air-tight sealing desirable. M. Villon accomplishes this by covering the cork and part of the neck with a thin layer of copper electrically deposited. For this purpose the neck of the bottle is coated with a conducting substance such as black-lead, zinc or copper powder, and plunged in a galvanic bath. This bath has a cover of paraffined wood with conical holes, which are lined with copper rings. All these rings are connected among themselves, and with the negative pole of the dynamo, while a copper sheet in the bath is connected to the positive pole. The bottles are simply inserted in the holes, neck down, and when a layer of $\frac{2}{10}$ to $\frac{3}{10}$ of a millimetre has been deposited the current is stopped. The deposit may be gilt or silvered, or given any desired shade in special baths. The process, of course, can be employed to seal bottles for mineral waters, preserves, and a variety of products.

Telegraphs on the Amazon.—With reference to the paragraph under this head in our issue of September 27, p. 337, we are further informed that the entire length of the route for the new cable about to be laid up the Amazon from Pará to Manaos under exclusive concessions from the Government of the Brazilian Republic is 1,365 nautical miles, and that there will be in all 16 stations on the line. The "Faraday," it is stated, will probably leave England next month with the cable, more than half of which is already manufactured. This long subfluvial line will for the first time bring these tropical regions, so increasingly productive of indiarubber, coffee, and sugar, into direct telegraphic communication with Europe. All past attempts on the part of the Brazilian Government to establish aerial lines through these districts have, it appears, failed, owing to the rapidity and density of the forest growths. Mr. Reidy, representative of the Amazon Telegraph Company, joined the expedition at Pará. The great importance of the Amazon as a trade route may be gathered from the fact that the "Faraday," a steamer of 5,000 tons burden, will proceed all the way up to Manaos, a distance of 1,100 miles from the mouth of the river.

Electricity v. Horses.—From the *Field* comes a wail of complaint that "the horse is likely to become extinct in the United States, or at all events to be seen only in museums and menageries. Electric traction has undergone surprising developments in that country, thus displacing horse power, which fails to find employment in other ways. The latest official reports show that over 10,000 miles of electric roads, with a total capitalisation of nearly 1,000 million dollars, are actually in working order, and that electricity is the motive power of no less than two-thirds of the gigantic number of street cars actually in use. In this connection it is important to remember that any town with at least 5,000 population in the United States would consider itself disgraced if it had not a public street car service. It is estimated that up to the present time 50,000 horses have been displaced upon the tramways. Nor is this all, for the extensive system of suburban and

Digitized by Google

country lines has made it needless for many families to keep a horse and carriage who once thought it necessary. Then, again, the horse, driven out of the tramways, driven out of the private carriages, finds a new competitor in the bicycle, which threatens him with actual extinction." The same doleful predictions about the noble animal were nevertheless everywhere heard on the introduction of railways.

Niagara's Fate.—The commissioners of the Niagara State Reservation have appended to their annual report an essay on the subject of the famous Falls by Prof. J. W. Spencer, who observes that the computation of the age of the Niagara River—based upon the measured rate of recession during 48 years, upon the changing descent of the river from 200ft. to 420ft. and back to 320ft., and upon the variable discharge of water out of the Erie basin only during three-fourths of the life of the River, and afterwards that of all the upper lakes—leads to the conclusion that the Niagara Falls are 31,000 years old, and the river of 32,000 years' duration; also, that the Huron drainage turned from the Ottawa River into Lake Erie less than 8,000 years ago. If the rate of terrestrial deformation continues as it appears to have done, this authority calculates that in about 5,000 years the life of Niagara Falls will cease. These computations are confirmed by the rate and amount of differential elevation recorded in the deserted beaches. It is further roughly estimated that the lake epoch commenced 50,000 and 60,000 years ago, and there was open water long before the birth of Niagara in even the Ontario basin, and that under no circumstances could there have been any hydrostatic obstruction to the Ontario basin since before the birth of Niagara Falls.

The Otto Apparatus for Producing Ozone.—The action of the ozonising apparatus invented by M. Otto is based on the partial transformation of oxygen into ozone under the influence of a continuous discharge. The ozoniser is enclosed in an oblong wooden box coated inside with a protective lacquering, which prevents the corrosive action of the ozone. The box rests on four glass feet. Inside there is a series of triple plates made up of two plates of glass, enclosing a sheet of aluminium foil or some other conducting material. The plates are perforated with several holes alternately at the top and at the bottom to allow the gas to pass. The end plates have only one hole each for the entrance and exit of the gas. Thin strips of asbestos at the edges of the glass plates keep them at a uniform distance of a millimetre from each other. To keep the system gas-tight, the two end glass plates are made slightly larger than the others, and the space left at the periphery of the others is luted with a suitable cement. The conducting plates are connected alternately odds and evens together by little tags, and the ends of each set coupled up to the terminals of a Rhumkorff coil or a high-tension alternator. The discharge takes place in the spaces between the successive plates, the oxygen to be acted on passing in a zigzag course through the holes alternately at the top and bottom of the plates.

The Telegraph Service in Chili.—The Chilian Minister of the Interior reports the reconstruction of 830 miles of telegraph lines during the past year, at a cost of 120,250dol., and the erection of 340 miles of new lines at a cost of 87,641·50dol. Forty lines, moreover, were repaired, at a cost of 10,128·50dol. With this outlay the service has been much improved. Direct communication between the principal offices has been completely established, whilst in the secondary offices the system of turns has been abolished. Previously these turns were a necessity owing to a deficiency of lines. One line more between Serena and Illapel, and the reconstruction of the line between those places, will, the Minister says, complete the telegraphic network of the Republic, and will be sufficient for all present necessities. In 1894, 12 new offices were opened, and three were closed for want of business. The number of messages transmitted in 1893 and 1894 shows a great increase over 1890, whilst the revenue in 1894 exceeded that of 1890 by 155,431·22dol. Similarly to the State railways, the telegraph lines of the Republic are the result of patient labour extending over many years. The precursor of the network of these lines was the "linea Americana" between Valparaiso and Santiago, which was constructed little more than 40 years ago, and as a company concern proved a failure. In Chili, as in England, telegraphs and post office are generally mentioned together, and the Minister reports a large increase in the business of the latter service.

Retirement of a State Telegraph Engineer.—Mr. J. E. Naylor, assistant-superintending engineer of the Postal Telegraph Department, has just retired, owing to failing health, from the active service of the General Post Office. Mr. Naylor has been associated with the electric telegraph for a period of 40 years, during which time he has taken an active part in the extensive work that has devolved upon the engineering department in connection with the extraordinarily rapid development of telegraphy, especially during the last quarter of a century. Joining the British Telegraph Company in 1855, Mr. Naylor was appointed clerk-in-charge of that company's office at Wakefield in 1860, and five years later he was promoted to a similar position at Sheffield. In 1868 Mr. Naylor became an inspector of the engineering department and had charge of all the Magnetic Telegraph Company's wires and apparatus upon the Lancashire and Yorkshire Railway, from Sowerby Bridge to Goole and Leeds, and also upon the South Yorkshire Railway from Barnsley to Sheffield and Doncaster. On the transfer of the telegraphs to the State, he was appointed to the York district, and carried out the extensive erections of new road lines that were then made from Beverley to Scarborough and Whitby, and from Leeds to Harrogate and Northallerton. On the rearrangement of districts that took place in 1878, Mr. Naylor was appointed to Leeds, where he carried out extensions and additions rendered necessary by the adoption of the sixpenny rate for telegrams. More recently he has taken an active part in the erection of the new trunk telephone lines that have been erected by the Post Office.

A New Form of Insulator has been devised by Messrs. Albert Vickers and Wm. Dibb, of Syracuse, N.Y. The insulator, the *Electrical Review* of New York says, is designed to do away with tie-wires. The idea to aim at in effecting a perfect support for any wire is to prevent its coming in contact at the insulator with anything that could injure it in consequence of the constant movement that exists there owing to swinging in the wind of the wires and working of the poles. In the insulator under notice the idea has been to support and fasten the wire and yet have it in contact with nothing but smooth rounding surfaces of glass or porcelain which could not possibly in any way injure it. The insulator consists of a body of the present form screwing to the pin with the top part provided with a cavity. The roller action of the plug prevents the wire from moving laterally, the plug keeps it from flying up, and it is therefore securely fastened. The plug cannot come out, for the pressure of the wire against a slight groove in it holds it to its place securely enough, as there is no strain on it tending to force it out. In addition to the advantages

Digitized by Google

already cited, the following points are claimed for the insulator: It fastens the wire more positively than a tie, and all corrosion is avoided. It is used more easily and quickly than a tie, and can be fastened very much more quickly. This saves time and money in constructing lines and the results are bound to be more satisfactory, as every fastening is uniform and is readily inspected from the ground, since if the plug is in position the fastening is all right. It is evident, therefore, our contemporary adds, that broken wires and crossed lines will be at a minimum on lines where this insulator is used, to say nothing of the very much less time required to construct a line with them.

Fog-Signalling by Searchlight.—There has been a discussion in the *Standard* as to the first inventor of fog-signalling by searchlight. Mr. Ronald A. Scott, M.I.E.E., writes, in reply to a letter by Mr. Nelson Harris, of Deal, that the intensity of a 6,000-c.p. searchlight would be insufficient to render a beam visible at 33 miles distance. It was this fact, he says, that caused Lieutenant Froude, R.N., to ask him to assist him with his (Mr. Scott's) powerful searchlight in his experiments, as the tiny one in use during the mimic sea battle, though, of course, capable of throwing a small vertical beam, was practically useless for the purpose of Lieutenant Froude's investigations. It will be apparent to anyone, he thinks, that, if the beam of light was seen at a distance of 33 miles from the exhibition, it was, doubtless, thrown from Mr. Scott's projector of upwards of 27,000 c.p., and not from one of only 6,000 c.p. Mr. Harris replies that as Mr. Ronald Scott indirectly concedes the point that he has been fighting for, that Commander Wells was the first to adapt a searchlight for the purpose of deflecting a beam of light vertically, he does not propose to go any further. He admits that it is more than probable that it was Mr. Scott's light that was observed at Frant. He adds that, from circumstances that have since come to his knowledge, it is possible that his claim for Commander Wells will have to be abandoned in favour of a commander in the Eastern Telegraph Company's service, who, he has been informed, was induced to make experiments with a searchlight at Malta and Gibraltar so long ago as in 1886, through having observed that the glare, or reflected light, of the Lizard light, sent horizontally, was visible at a distance of 50 miles. Had a light of such intensity been purposely directed vertically, it is difficult, he imagines, to say at what distance it might not have been seen. Unfortunately, Lieutenant Froude is at present absent from England.

Electric Lighting of Tunbridge Wells.—The ceremony of the official opening of the electricity works at Tunbridge Wells was conducted on Wednesday last with unusual demonstration. The programme commenced with a gathering of guests in a large hall, where the hospitality of the mayor (Sir David Salomons) was dispensed, after which followed speeches of the usual order. Councillor Ashby Wood, as chairman of the Electric Committee, handed to the mayor the key of the works, after referring in glowing terms to the prospective advantages which would accrue to the ratepayers from the fact of their having kept the electric lighting of the town in their own hands. Sir David Salomons, in reply, stated that the demands for the light had more than fulfilled his expectations, and dwelt upon the advantages to be derived from the use of electricity for public and private purposes. Mr. Preece also spoke, and a vote of thanks was accorded to the mayoress. A procession of the public bodies of the borough was then formed, and proceeded to the central station in the Corporation yard. Here the mayoress switched on the new light, and, after a parade of the town, a visit was paid to an electrical exhibition held at the Town Hall. This exhibition contains an extremely creditable collection of apparatus and fittings, displays of various apartments artistically fitted with incandescent and arc lamps, heating and cooking apparatus, ventilating fans, telephones, bells, cigar lighters, night lights, together with a host of minor novelties to which the energy of current force is now applied; and the mayor has equipped a stand with a highly interesting set of scientific appliances. In addition to a large number of local firms several London houses send exhibits. One of the most attractive displays is a happily-conceived design of partly-concealed and variously-coloured lights embowered in fernery, foliage, and rockwork.

Compulsory Use of Fenders.—The Massachusetts Board of Railway Commissioners has promulgated the following order requiring street railway companies to equip their cars with fenders: "All cars run by a street railway company on a highway, townway, or travelled place (excepting cars run by horse power, cars run only as trailing cars, and, until the further order of the Board, cars run wholly within the limits of towns whose population is less than 7,500 each), shall be equipped with fenders and wheelguards in accordance with one of the two following methods: either (1) with a fender at the front of the car (going in either direction), and also with wheelguards underneath the car; or (2) with a fender at the front of the car of such design as to serve also as a wheelguard. In the first case (1) the fender shall consist of a platform, netting, or other similar device, constructed and arranged so as with reasonable certainty to pick up a person who is run into while standing, but to pass over a person who is lying on the ground, without probable injury to the person in either contingency; and the wheelguards shall be of such construction and arrangement or method of operation as to prevent, so far as practicable, a person who has fallen or been thrown down from being run over by the wheels. In the second case (2) the fender shall be of such construction, arrangement, and method of operation as not only to pick up as aforesaid a person who is run into while standing, but also to prevent, as far as practicable, a person who has fallen or been thrown down from getting under the car and being run over by the wheels. This form of fender shall accordingly include a device by which, in case of emergency, it can be lowered by the motorman, and when lowered held down close to the ground." These regulations are to take effect on November 14, 1895. The Board of Railroad Commissioners of Massachusetts enjoins, furthermore, that the several street railway companies shall equip such electric box cars as are used by them for the transportation of passengers in the months of November, December, January, February, or March in each year, with suitable apparatus for heating them by electricity.

"That Terrible Telephone."—In the course of a leader with this title the *Financial Times* remarks: In order to give the telephone a fair trial we made an impromptu experiment last night from the offices at which this journal is printed, two members of our staff joining in the trial, having separate receivers attached to the same instrument, and adhering rigidly to the printed rules. In the first instance, after listening for a reply from the exchange, and getting it, we were asked for the number of the subscriber wanted, and gave that of our City telephone. Nothing happened for some little time, and then the operator remarked, "Well?" It turned out that she had not heard the reply. Finally, communication was established in the strictly limited sense of the London telephone—that is to say, it was clear to the subscriber at each end of the wire that somebody was talking to him

Digitized by Google

from the other end. But intelligible conversation was found impossible, even to the extent of explaining the object of the call. While efforts to this end were in progress, our representatives learned with interest that somebody unknown was "wanted at the Adelphi," together with a quantity of other information which was only relevant to the object of the call in that it emphasised one of the most glaring defects of the system. Next we tried Brighton, and asked for the Métropole Hotel there. The reply came promptly that we could not be put through, and our natural rejoinder was, "Why?" The operator promised to enquire, thereby breaking one of these precious rules, which says "that the operators are strictly forbidden to answer any question." We should feel very thankful if conversation between subscribers were as clearly audible as was the altercation which ensued between the operator who had said we could not get through and the one who had conveyed us the message. Ultimately we were told it was a mistake arising from an idea that our printing works were a hotel. Why that should have prevented our talking to another hotel, we know not; but such was the explanation given. After a little more delay, we were asked if we knew that there would be a charge of a shilling; and having satisfied the exchange that we were willing to risk that sum, the desired communication was effected. From Brighton every word was audible, in spite of the conversation which was going on at the same time on the London wires as to a place of amusement for the evening. This experiment was quite unpremeditated. Our representatives did their best in every way to give the telephone and its operators a fair chance. The results as above stated are in no way exaggerated; nor are they an exceptional experience. Surely there must be some remedy for this sort of thing.

The Paris Municipal Regulations for Indoor Electrical Installations, which were recently issued, are embodied in 16 clauses. No. 1 enjoins that electric installations supplied by a concessionee of the city of Paris must satisfy the conditions laid down both at the time of their establishment and at any period of their use. No. 2 sets forth that the metal entering into the composition of the cables and wires must be of a resistance equal at most to 1·8 microhm-cm. at 20deg. C. No. 3 is as follows: The metallic section of the conductors must always be such that the accidental passage of a current of double the normal intensity should not result in a temperature of above 40deg. In every case the current density must not exceed three amperes per square millimetre for sections of 1mm.^{2} to 5mm.^{2}, two amperes per square millimetre for sections of 5mm.^{2} to 50mm.^{2}, one ampere per square millimetre for sections above 50mm^2. (This amounts to about 2,000 amperes per square inch for wires from Nos. 13 to 19 B.W.G., 1,300 amperes per square inch for wires from Nos. 1 to 12 B.W.G., and 650 amperes per square inch for larger sizes.) When bare wires are used the figures indicated should be doubled. No conductor must be used the core of which consists of a single wire of a smaller diameter than $\frac{9}{10}$mm. No. 4.—Outside the switchboards all the cables and wires must be both insulated electrically and protected mechanically. For wires placed in damp situations the covering must be waterproof. No. 5.—The safety fuses must be easy to replace, and must not cause projections of the melted metal. They must fuse at a current of at most three times the normal. No. 6.—The insulating material forming the base of the switches must be suitable to the situation they occupy. They must not be heated by the passage of the current. They must always remain at a temperature that the hand will bear. No. 7.—Each wire of a private connection must be furnished with a cut-out and a switch. No. 8.—When motors, transformers, or accumulators are used, they must be fixed so as to avoid all risk of accident. Special precautions must be taken to insulate them and place them beyond the reach of persons who are not called upon to deal with them. The places where accumulators are located must be suitably ventilated. If there be employed a primary difference of potential exceeding 800 volts for a continuous current, or 500 volts for an alternating current, the secondary installation must be effectively protected against a contact between the two circuits. No. 9.—Each part of an installation must be easily distinguished and insulated from the whole. Each circuit must be provided at the outset with a double cut-out; every lead must be equally so provided, also every sub-division in which the intensity may reach five amperes. No. 10.—The means employed to fix the conductors must both ensure their insulation and avoid damaging the cables or wires; where cables cross, there must be supplementary insulation and mechanical protection. Along walls and ceilings the mechanical protection should be a tube of some hard material with rounded edges. No. 11.—In the portions of cables intended to be united by splicing, the cleaning shall be done with a substance which does not affect either the metal or the insulating material; the use of acids is proscribed. The joints must not weaken either the metal core, nor the insulating covering, nor the mechanical protection. No. 12.—The moulding must have no discontinuity in the angles, curves, and joints. The edges of the grooves must be rounded off at each turn. Cables and wires must never be fixed in the mouldings by means of nails or staples. No. 13.—The greatest care must be exercised in the fixing of electroliers. The conductors attached to them shall have the best insulation and strictly follow the forms of the fittings. In electroliers with five or more lamps, joints must be avoided; the wires of each lamp shall be preferably united to the source of supply on metal crowns furnished with screws. Sockets shall be fixed so that they cannot turn; they should, further, be electrically insulated from the body of the fittings. No. 14.—Each arc circuit shall include a switch, and on each pole a cut-out. If rheostats are used, these shall be placed in a sheltered situation, remote from inflammable material. The wire of the rheostat must not heat above a temperature of 200deg. in ordinary working, and must be separated by an air-gap of at least 5cm. from the wall or the table carrying the rheostats. These fittings shall be mounted on incombustible and non-hygrometric material. No. 15.—When the installation comprises both gas-pipes and electric conductors, the following special regulations apply: (*a*) the fittings serving both for gas and electricity shall always be mounted on a bracket the insulation resistance of which shall be at least 500,000 ohms, and which shall be so arranged that this insulation cannot be impaired by dust and damp; (*b*) wires attached to fittings used for both gas and electricity shall be well insulated and protected from the heat of the gas. Clause No. 16 gives the method of determining the insulation: over every part of the conductor capable of being separated from the system by switching or by the removal of a fuse, the insulation resistance, either with reference to the earth, or to the conductor with the contrary sign expressed in ohms, should not go below $5{,}000\,\frac{E}{2}$, E being the difference of potential in volts measured at the terminals of the generators or current transformers. In measurements of insulation the difference of potential employed must be equal to E, without, however, going above 500 volts or below 100 volts.

STAFFORD ELECTRICITY WORKS.

There is always a feeling of exultation when we see a historic town acclimatising itself, so to speak, to modern requirements, and thus making continuous its title to enlightenment. We speak about enlightened citizens—up-to-date men, *fin-de-siecle* councils—as indicating that

MR. C. H. WRIGHT, MAYOR OF STAFFORD.

those to whom the name is applied realise the progressive nature of things, that there must be from time to time a putting aside of that which is old and the taking up of that which is new. Stafford comes under this category. It is an ancient town—an historic town, by the Saxons called Stadeford or Stadford, and mentioned in earlier times as

MR. J. FERGUSON BELL, A.M I.C E., ENGINEER OF THE ELECTRICITY AND GAS DEPARTMENT.

Betheney. Subsequently it is described in Domesday Book as having only 18 burgesses belonging to the king, but a larger number looked possibly to the Earl of Stafford as overlord. From the time of the Saxons, too, there was a castle, which was from time to time destroyed and as often rebuilt till demolished by order of the Parliament during the Civil Wars, after which it was only partially rebuilt. An older charter was confirmed and enlarged by King John and again by Edward VI. In 1876 the borough and municipal boundaries became identical. The principal trades of the town are tanning and the manufacture of shoes. Such is the brief history of a town which will

DR. JOHN HOPKINSON, M.A., F.R.S., M.I.C.E., CONSULTING ENGINEER FOR THE ELECTRICITY WORKS.

inaugurate the electric light as a municipal work on Tuesday, the 15th inst.

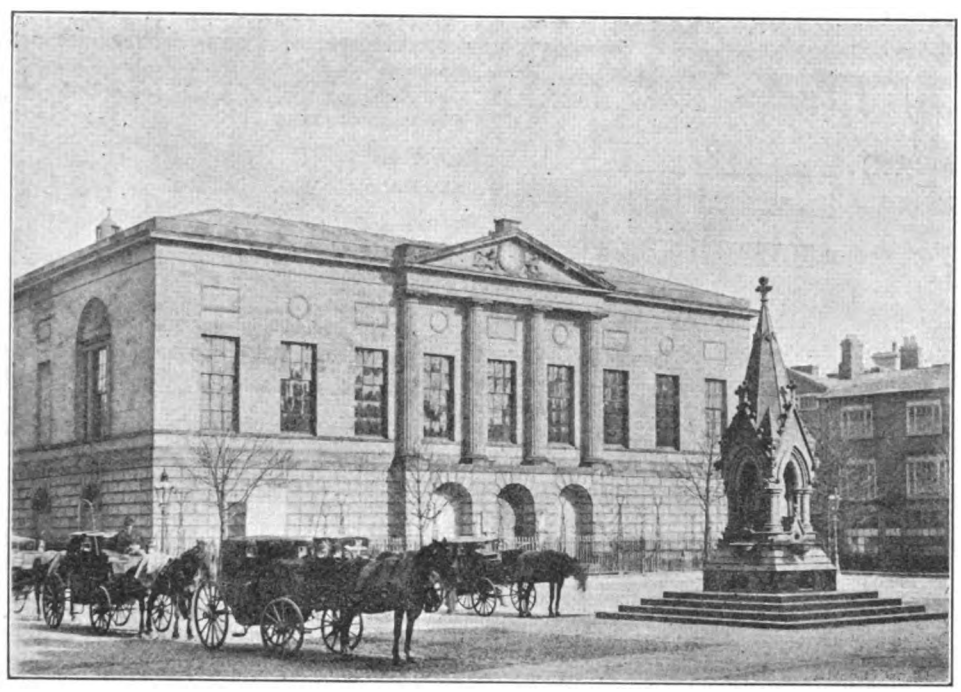
The history of the electric lighting movement at Stafford dates back to early in 1889, when a provisional order for the supply of electricity was obtained by the Corporation. Mr. J. Ferguson Bell, the gas engineer to the borough, was

ALDERMAN W. H. PEACH, J.P., CHAIRMAN OF THE ELECTRIC LIGHTING COMMITTEE.

then instructed to prepare a report as to the probable cost of laying down an electric lighting plant to supply the scheduled area. Mr. Bell's report was presented to the Council in September of the same year, and it is interesting to note that many of its recommendations have been now carried out. For instance, the advantage of placing the new works on the same site as the gasworks was pointed

Digitized by Google

out. The estimated cost, also, did not differ greatly from the cost of the present plant. The following clause, however, shows that the engineer considered caution to be necessary. He stated that: "Unless sufficient consumers can be obtained within the scheduled area who will undertake to pay for not less than six 16 c.p. incandescent lamps each during a period of two years at a fixed price per light, and making an aggregate number of lights equal to 1,200



THE SHIRE HALL, STAFFORD.

16-c.p. lamps, and yielding a revenue of at least £2,400 per annum, the Town Council would not be justified in establishing electric light works." The Council accordingly ordered a canvass of the town to be made to ascertain who would take the light, presumably on the above terms. Anyone who has had any experience of the results of such canvassing will not be surprised to learn that only two townsmen cared to bind themselves for the two years, and hence the matter was allowed to drop for a time. Such has, we believe, been always the case, and no true estimate of the demand can be obtained in a town till the light is actually ready for supply. When, however, the provisional order was about to expire, fresh steps were taken, and Mr. Bell was authorised to obtain further expert advice from Dr. John Hopkinson on the question. The report from this gentleman was received in August, 1893, and since that date the matter has been pushed forward as rapidly as possible.

The following extracts from Dr. Hopkinson's report are of interest to the general reader: "The town of Stafford presents both favourable and unfavourable conditions in regard to electric lighting. Coal is cheap, water for condensation is accessible, and it would be easy for the Corporation to combine in a measure their electric light staff and the staff employed in the production of gas; these conditions all tend to economy of production. On the other hand, the demand for electric light in the town is not likely to be very large, and there will be many consumers whose demand for a supply will last for a short time only, whose account will therefore be small, but for whom it will be necessary to incur considerable expenditure for plant. The first point to be decided is the site upon which the generating machinery is to be placed. In this respect you are fortunate, inasmuch as you have an excellent site at the gasworks which is not likely to be required for the production of gas. This site presents the advantage that, if steam be used, the boilers can be utilised for the purpose of the gasworks when they are not required for the production of electric light. From this will result a considerable economy of coal and wages. The site, too, is in proximity to the district where at first the principal demand may be expected. I am therefore of opinion that there can be no doubt whatever that the gasworks site is the right site for you to adopt. The site for the generating

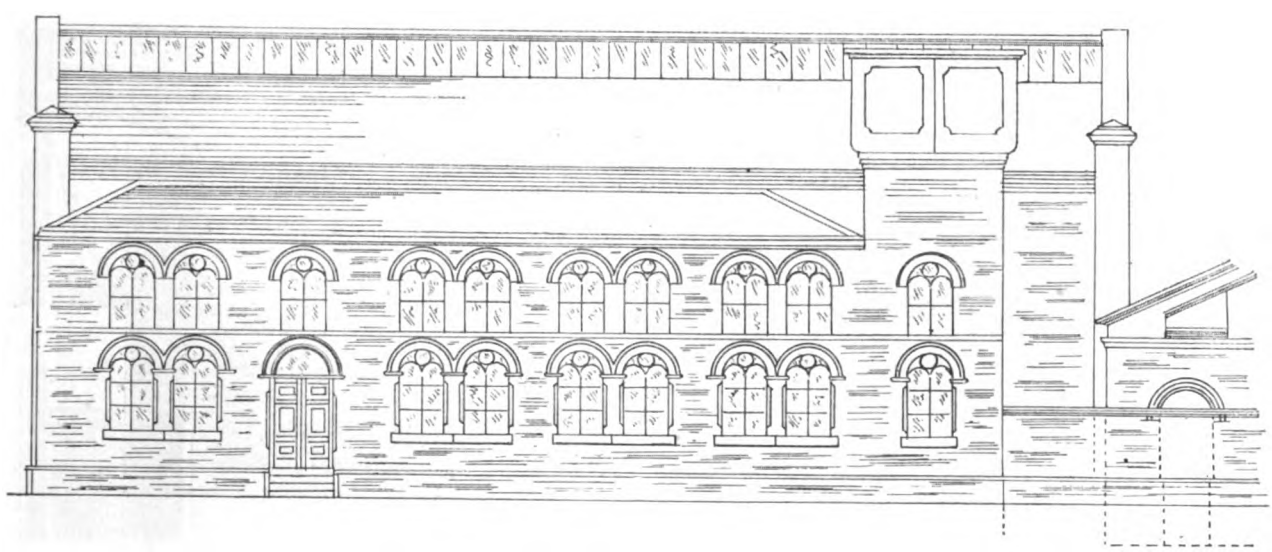


FIG. 1.—Front Elevation of the Stafford Electric Lighting Works.

Digitized by Google

plant having been decided upon, the next question is, what is the right system of supply to adopt? The whole of the lighting which you will have to do at first is comprised within a distance of about 700 yards from the generating station. It is now well recognised by all electric light engineers that when the district to be lighted is so near to the generating station, the proper system to adopt is that applied to the supply of mechanical power. I should therefore advise you to adopt the continuous current with the system of conductors known as the three-wire system, which enables you to materially increase the pressure at which you work, and therefore to diminish the size and cost of your conductors. I should also advise you to make use of accumulators. If at a future time a demand for

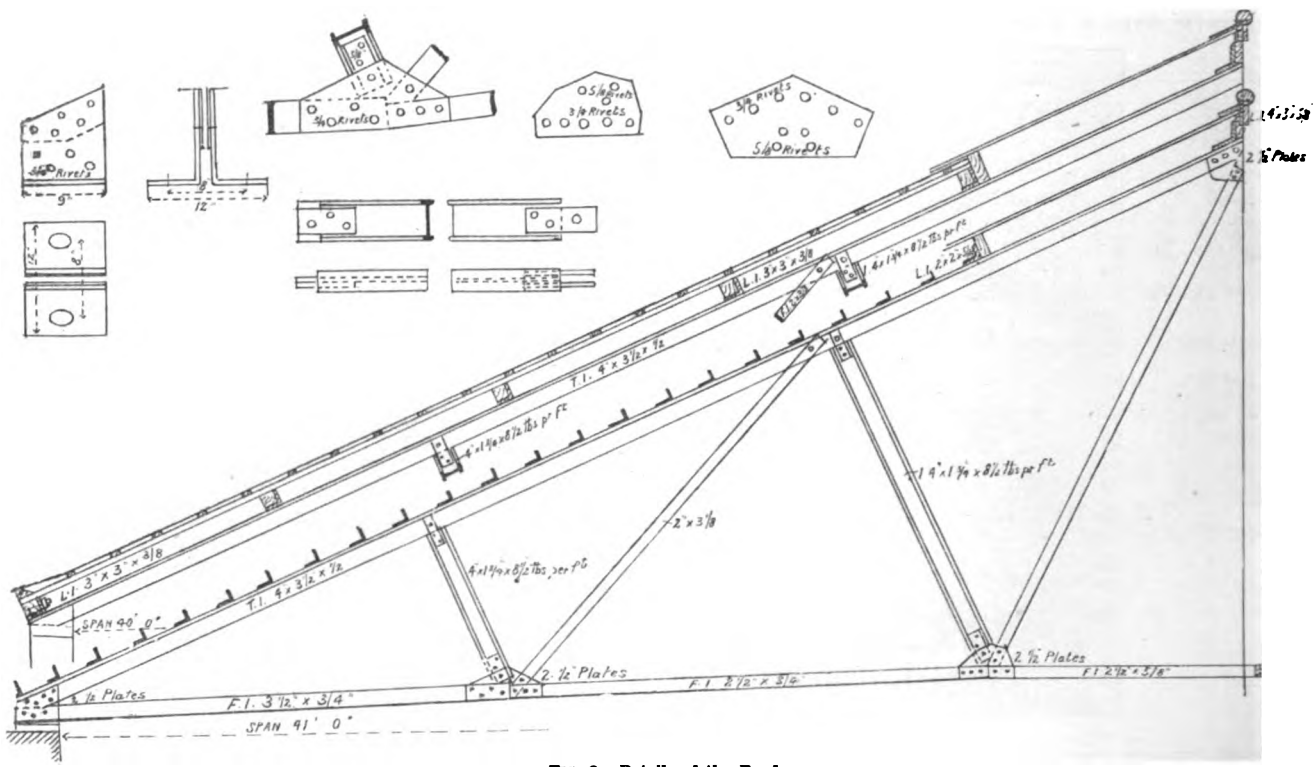

FIG. 2.—Details of the Roof.

with continuous currents at low pressure. The continuous current has the great advantage that with it accumulators may be used. These are continually becoming cheaper, and even at their present price they are of great service in small stations, such as yours will be, in enabling the machinery to be stopped during the greater part of the 24 hours, so economising the wages of the attendants, who otherwise would have to be present for the purpose of supplying a very few lights. They have also the advantage that they enable you to increase to a material extent the maximum output of the station, inasmuch as you are able to add the output of the accumulators to the output of the machinery. The continuous current has the further advantage that it is more readily

electricity arises at a greater distance from the station, this would be met by putting down a battery in the neighbourhood of the demand, and charging the battery from the station directly, if the distance did not exceed a mile, by means of a transformer if it was more considerable. One question still remains—as to the motive power to be used

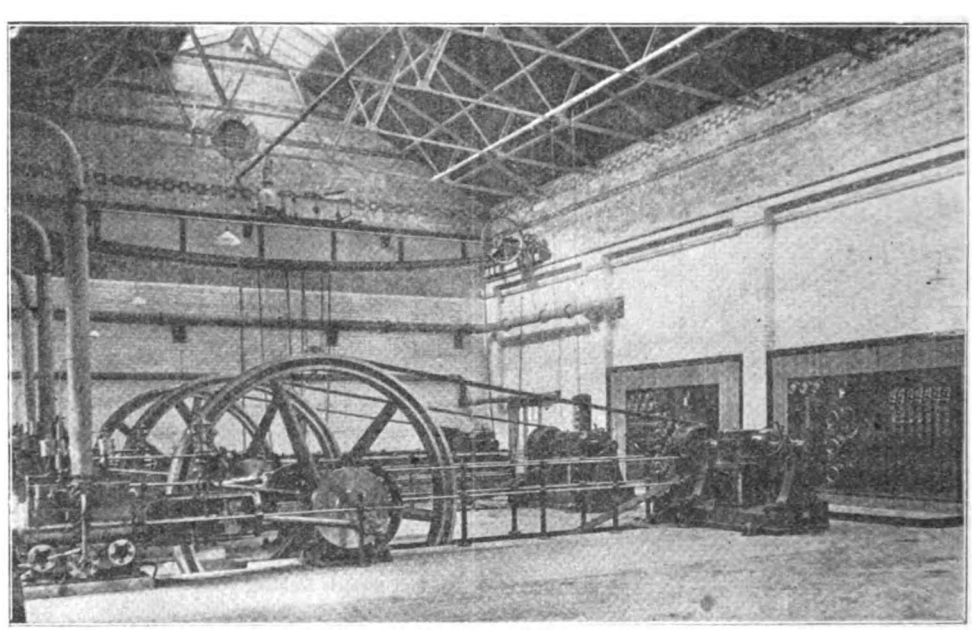

FIG. 3.—View of the Engine-room at Stafford.

It has been suggested that gas-engines should be adopted. I have not the least doubt that a perfectly satisfactory result could be attained with gas-engines. I should, however, prefer steam for two reasons—firstly, if gas-engines be used it is necessary to increase the number of accumulators employed, in order to secure that steadiness of light which is essential; accumulators, of course, are costly instruments, and it is not desirable to increase

Digitized by Google

their numbers beyond what is really necessary. Secondly. on anything but a small scale steam is cheaper than gas, I consider it is absolutely necessary for the Corporation to will be speedily required, I should advise you to go to the Local Government Board for permission to borrow a larger sum."

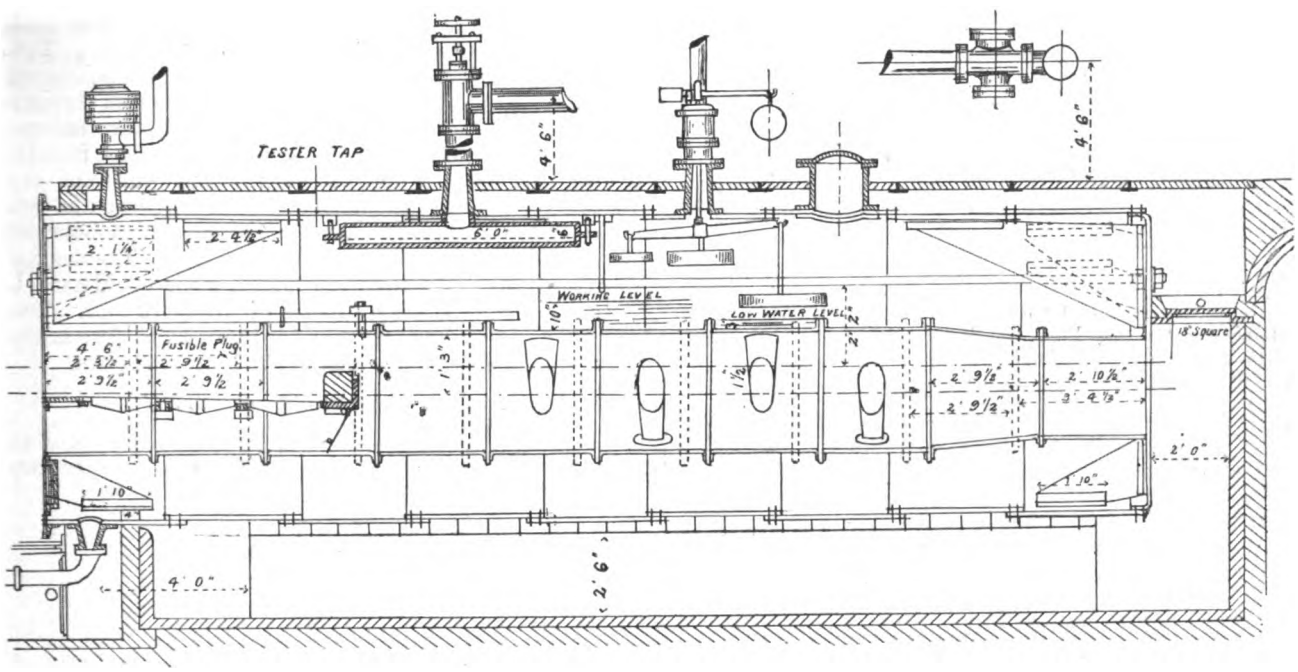

FIG. 4.—Detailed Section of the Lancashire Boilers.

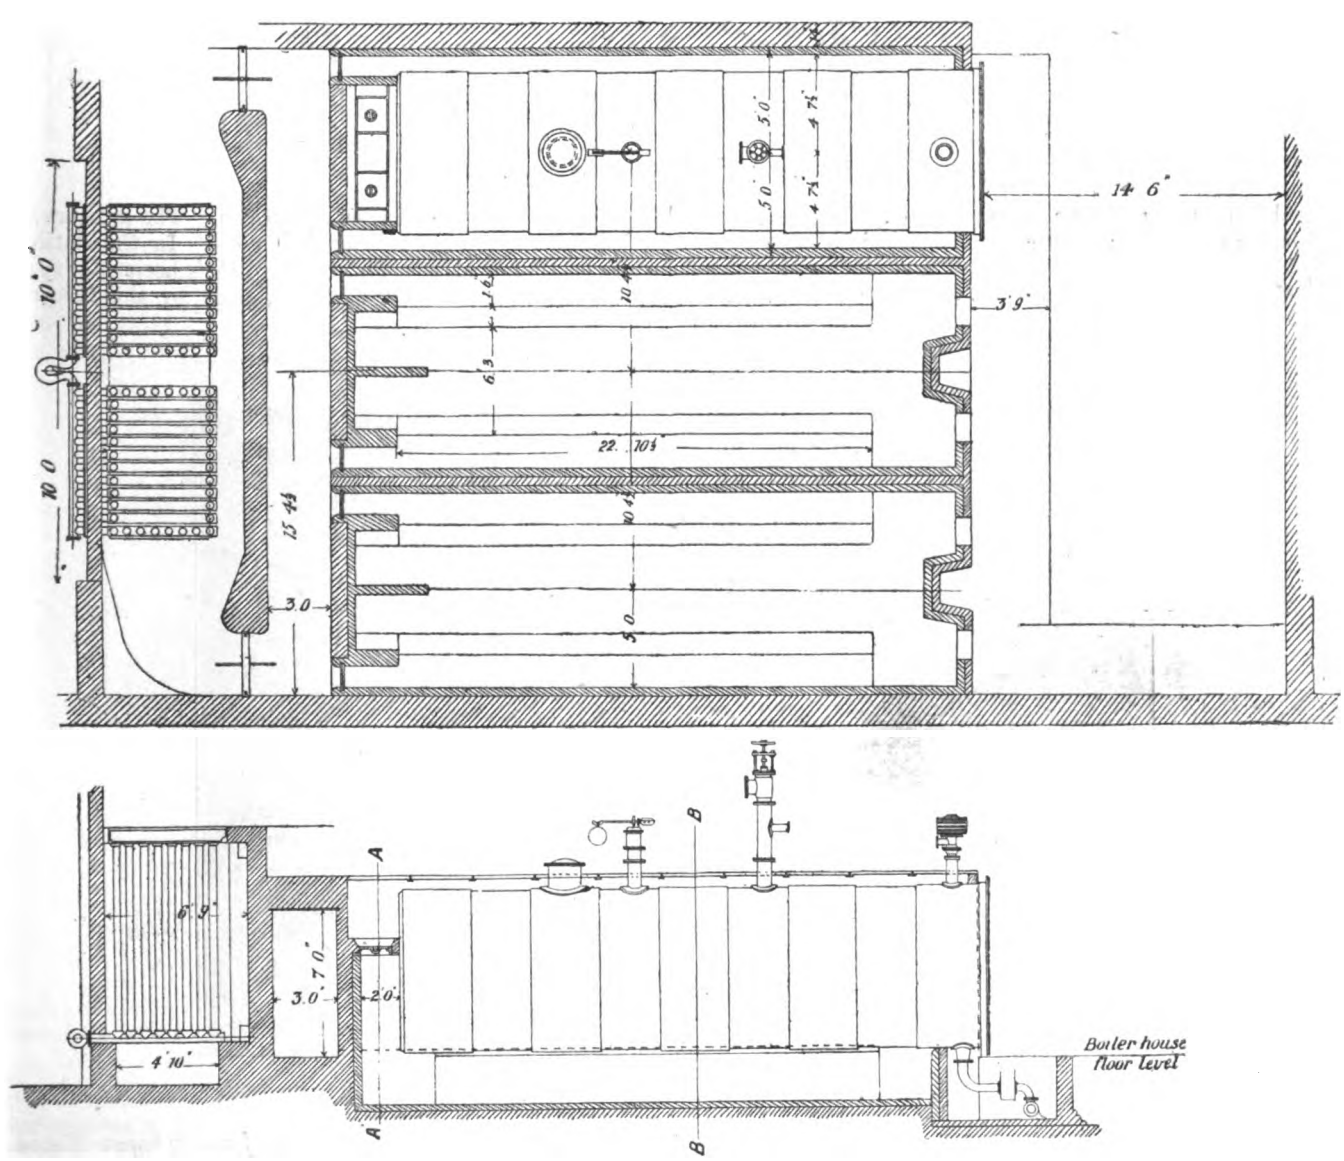

FIGS. 5 AND 6.—Details of the Boiler Seatings.

incur an expenditure of £12,000. In this estimate there is an adequate allowance for contingencies, but meters are not included. As, however, I think that further extensions

Dr. Hopkinson's estimate included all apparatus required for lighting simultaneously 5,000 8-c.p. lamps, and he gave figures to prove that the station would be financially suc-

cessful. It was decided to apply to the Local Government Board for permission to borrow £20,000, and, after an enquiry being held in December, 1893, the loan was sanctioned. Specifications were accordingly prepared and tenders invited, with a result that the following contracts were entered into for the supply of materials, etc.:

Foundations, etc., the Corporation	£1,837
Boilers, including boiler-feed pumps, economisers, and steam-pipes, Hick, Hargreaves, and Co., Limited	2,198
Engines, including steam-pipes in engine-house and pumps for condensing, Marshall, Sons, and Co., Limited	2,420
Dynamos, Electric Construction Corporation	1,151
Switchboards, Electric Construction Corporation	505
Mains, Siemens Bros. and Co., Limited	1,290
Traveller, T. Smith, Rodley	185

Accumulators, Chloride Electrical Storage Syndicate	882
Exhaust-pipes, W. Bagnall and Co.	75
Overhead tank for condensing purposes, C. and W. Walker	117

Buildings.

The whole of the designs for the buildings were prepared by Mr. J. F. Bell, and that gentleman is to be congratulated on the general appearance of the station. The site chosen is in the east corner of the land attached to the Corporation gasworks, where there is ample space for extensions. The present buildings extend over an area of 70ft. by 130ft., and consist of a spacious and well-lighted engine-house, boiler-house, accumulator-room, and offices. The buildings are of red brick, with stone and blue-brick facings, the engine-room being lined with white glazed bricks. A dado of coloured glazed brick forms a pleasing relief, and adds to the general appearance of the room. The front elevation of the building is shown in Fig. 1, while Fig. 2 shows some details of the roofs, which were designed by the engineer. The construction, as will be seen, employs rectangular sections throughout, and combines economy with strength. The foundations were not easily obtained, as there is a good depth of peaty subsoil under the building. This necessitated a liberal use of piling. Piles of pitch-pine are employed, of about 40ft. length. These are driven through into the gravel and then braced together with cross-timbers. On these a 3ft. bed of concrete is placed to form a foundation for the footings of the walls. The whole of the foundations for the machinery in the engine-room are supported on piles, and there is no connection between these foundations and those for the building. The engine-room is spanned by a travelling crane, made by Messrs. I. Smith and Co., of Rodley, capable of lifting 12 tons. The chimney is of circular section, and is 135ft. high. The inside diameter at the top is 6ft., and at the bottom 7ft. 3in.

General Conditions of Supply.

The station is designed to supply on the low tension three-wire distribution system, with five low-pressure feeders connected to the outside mains. The pressure of supply to the consumer is at 100 volts. In the station, three engines of Messrs. Marshall and Co.'s horizontal type drive three direct-current dynamos, made by the Electric Construction Corporation, by means of cotton ropes. These are each capable of giving 66 kilowatts at a pressure of 220 volts. Fig. 3 gives a general view of the engine room. The dynamos supply by means of feeders the two outside wires of the three-wire network, and the balancing current is provided by one or other of two sets of Chloride accumu-

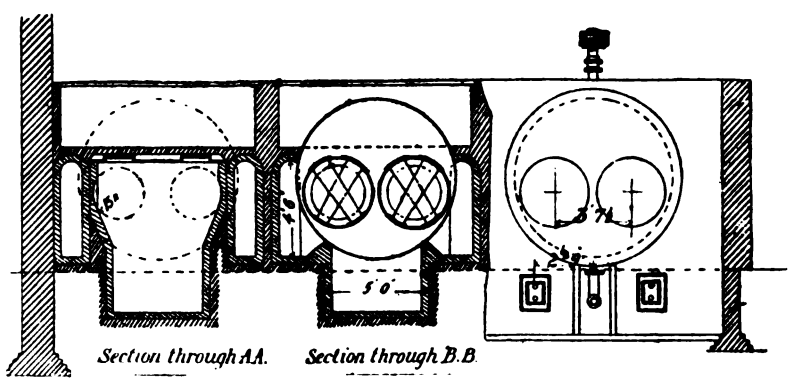

Fig. 7.—Transverse Sections of Boilers.

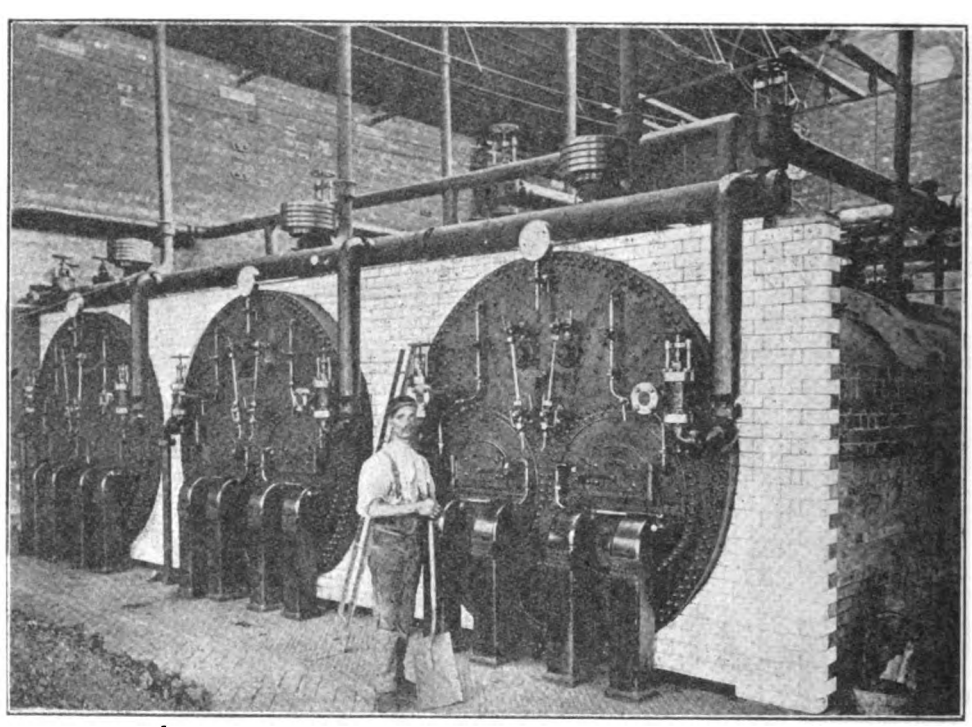

Fig. 8.—View of Boilers, showing Meldrum's Blowers.

Digitized by Google

lators. The accumulators are also intended to materially assist the generating plant at heavy loads and to supply the whole of the light load periods, when the demand is not sufficient to warrant the running of an engine. At such times of light load the boilers will be used to supply steam to the gasworks, and hence will be always under steam should sudden demand arise. In return for this advantage of using the steam, the gas department will supply to the electricity works all their refuse coke and coke screening free of charge. There is also a proposed arrangement for

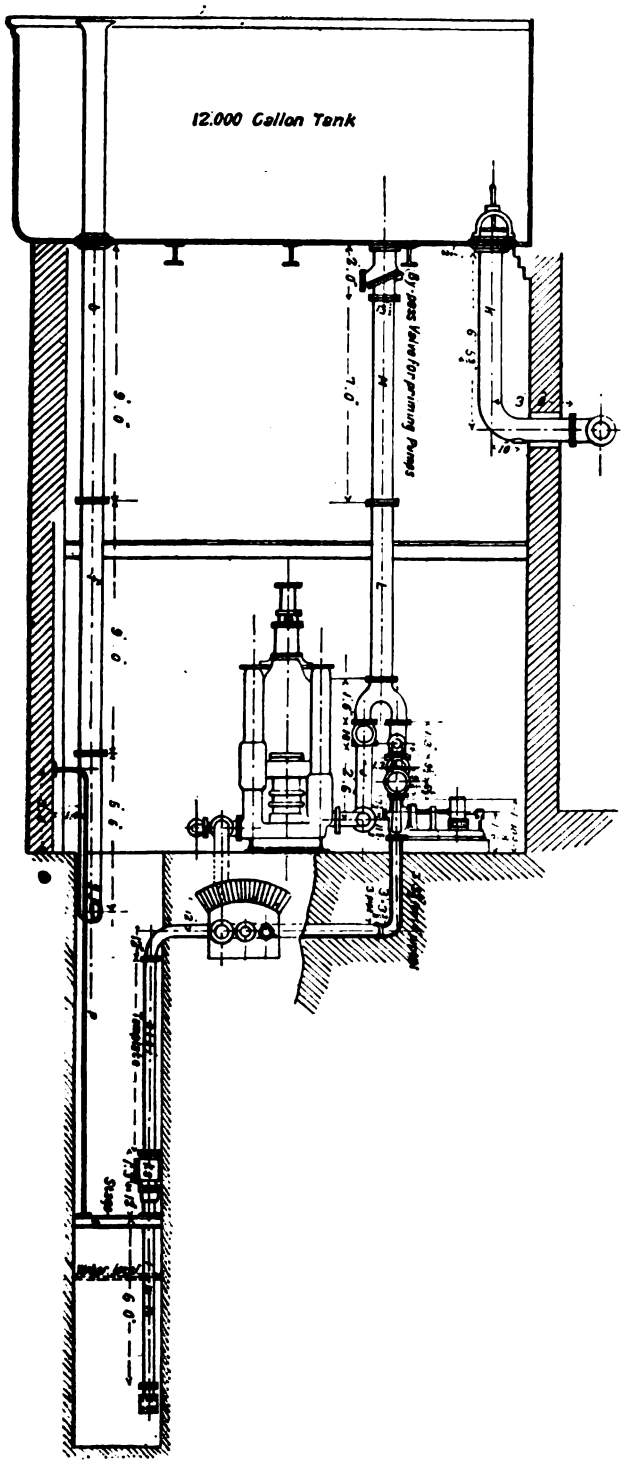

FIG. 9.—Sectional Elevation of the Pump-house.

cash payment as well, which would practically nullify the usual fuel charges in the electric works.

STEAM GENERATING PLANT.

The present boiler plant consists of three Lancashire boilers, made by Messrs. Hick, Hargreaves, and Co., of Bolton. The specification for these boilers was prepared by Mr. J. F. Bell, and submitted to Dr. J. Hopkinson for approval. The boilers have the following leading dimensions: Length, 28ft.; diameter, 7ft. 6in. The two flues have an internal diameter of 3ft. at the furnace end, and taper down to 2ft. 6in. at the other end, as shown in Fig. 4. Thickness of plates: cylindrical shell, $\frac{5}{8}$in.; flue tubes, except end rings, $\frac{1}{2}$in.; end rings of flue tubes, $\frac{9}{16}$in.; end plates, $\frac{5}{8}$in.; outer cover strips, $\frac{5}{8}$in.; inner cover strips, $\frac{7}{16}$in.; gusset plate, $\frac{5}{8}$in. Angles: front end of shell, $4\frac{3}{4}$in. by $4\frac{3}{4}$in. by $\frac{11}{16}$in.; gussets, $3\frac{1}{4}$in. by $3\frac{1}{4}$in. by $\frac{9}{16}$in.; $\frac{13}{16}$in. rivets are used throughout the shell.

All the plates, angles, and rivets are of the best Siemens-Martin steel, tested under the supervision of the National Boiler Insurance Company. Two $2\frac{1}{2}$in. diameter longitudinal stays are placed in each boiler, and have ends enlarged and screwed $2\frac{1}{2}$in. diameter. Four conical welded cross-tubes of $\frac{3}{8}$in. steel are fitted in each of the flue tubes, the cross-tubes being about $5\frac{1}{2}$in. diameter at the bottom end. Figs. 5, 6, and 7 show details of these three boilers and their settings, and Fig. 8 is a view taken from one corner of the firing space of the boiler-room. The following boiler mountings are attached to each boiler, and are designed for a working pressure of 125lb. per square inch: a Turnbull patent dead-weight safety-valve, $2\frac{1}{2}$in. diameter, having suitable waste-pipes to discharge the steam outside the boiler-house; a Hopkinson patent "Duad" high-steam and low-water safety-valve (1890 patent); a Hopkinson patent "Triad" junction-valve, with brass valve and seating, fitted with regulating screw, spindle, and handwheel (the above valve is 6in. internal diameter); a $2\frac{1}{2}$in. Hopkinson patent

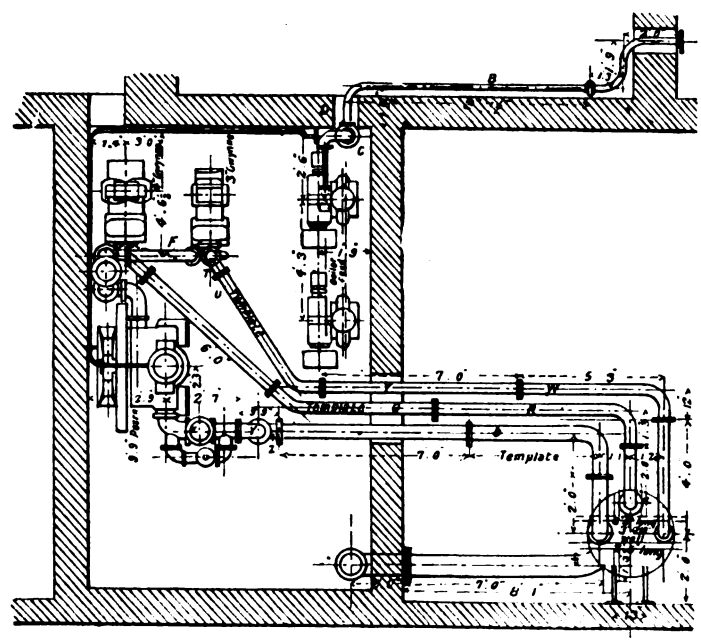

FIG. 10.—Plan of Pump-house.

accessible check-feed valve, combined with back-pressure arrangements and regulating screw, and so arranged at the front end as to be within easy reach of the attendant also; two gauge glasses of the patent safety type by the above maker, a steam-pressure gauge, and a blow-out cock.

The furnaces of these boilers are of the "Meldrum" forced-draught type, which are now being extensively adopted to enable any kind of cheap fuel, such as coke breeze, common slack coal, or anthracite coal, to be used, which is a great advantage. A further important advantage is that when a sudden demand arises from any cause, such as fog or thunderstorms or the like, which under ordinary conditions is most difficult to supply, with this system the boilers may be instantly forced and the evaporation increased without any trouble. Messrs. Meldrum Bros. have recently introduced an improvement, which has been adopted at Stafford, by which what we should consider the chief drawback to the adoption of this system at electric supply stations has been overcome, and that is the noise occasioned by the inrush of atmospheric air and steam through the blowers. This has been entirely overcome by means of an ingenious contrivance which introduces resistance in the air-admission passage, and in this way silences the blower. The needful air supply is obtained through special tubes, which are the subject of a protecting patent, and which pass through the foot-plates. Fig. 8 shows the silencing apparatus in position. We understand that the boilers at the Islington electric supply

Digitized by Google

station, which are to be supplied with the "Meldrum" furnaces, are also to be similarly fitted with this special improvement.

The furnace bars are placed specially near together to enable the coke breeze from the gasworks to be used, and then occasionally, when heavy demand arises, coal will be added to increase the output of steam.

from the sudden and dangerous strains to which flywheel pumps are subject. They work at a moderate speed, and by means of special valve gear the pistons are slowed down towards the end of the stroke, and the valves have time to settle into their seats. This also prevents any jar or shock, as there is no sudden reversal of the piston. Another feature of the design is the large water area through the

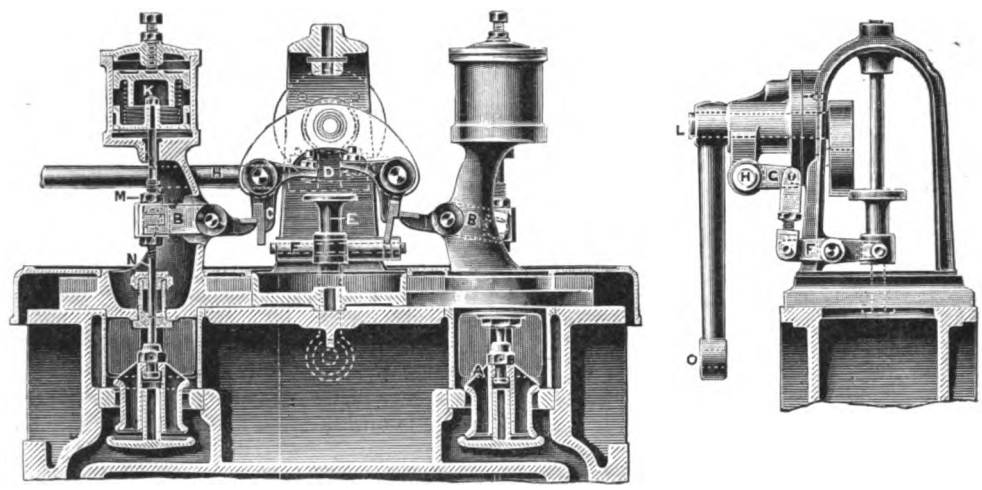

FIG. 11.—Details of the Proell Valve Gear.

The economiser is on Messrs. Green's new principle, and is constructed from improved strengthened patterns, suitable in every detail for a working pressure of 125lb. to the square inch. The whole is of the best material, approved construction, and workmanship, and tested to a pressure of 350lb. per square inch before leaving Messrs. Green's works. The economiser is arranged in two groups, with expansion

valves, which are of a special type for high-pressure boiler feeding. There is no dead centre, and the pumps will start at any part of the stroke. The length of the stroke and the requisite amount of clearance can be adjusted in a few seconds. The pumps are fitted with special buckets, and are compact and well finished in every way.

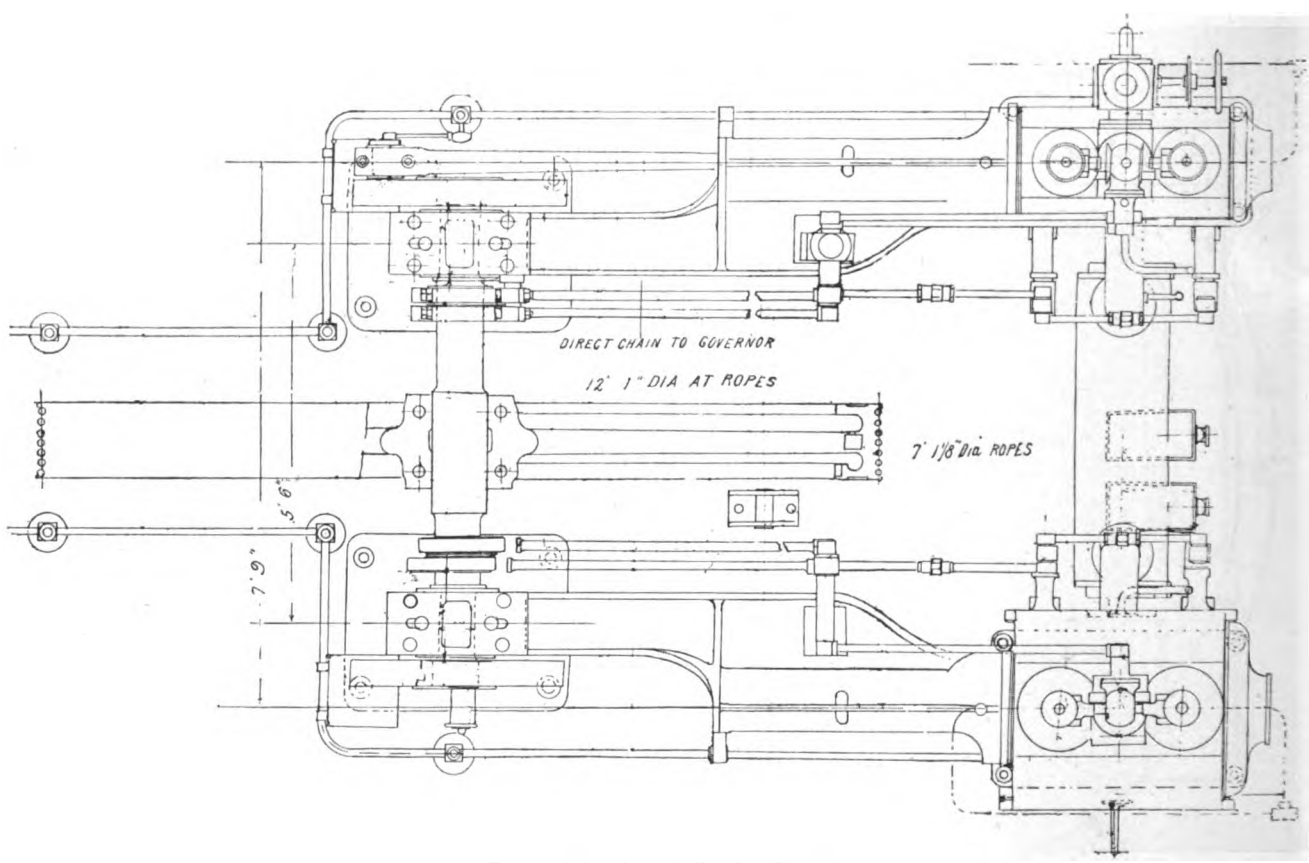

FIG. 12.—Plan of Marshall 90-h.p. Engine.

elbows top and bottom, and is provided with a 3½in.-cylinder engine for driving the scraping gear. The economiser consists of 128 tubes $4\frac{9}{16}$in. diameter and 9ft. long.

FEED-PUMPS.

The boilers are fed with two of Weir's patent feed-pumps, 6in. by 15in. stroke, made by Messrs. G. and J. Weir, Limited, Holm Foundry, Cathcart. These pumps are of the direct-acting type, and are consequently free

An alternative method of feeding is provided by the use of three Giffard injectors, supplied by the Patent Exhaust Steam Injector Company. These are made of gunmetal throughout and are cross-connected, so that any injector can be made to supply any boiler. The feed-pipes also are so arranged that the feed water may either be supplied direct or through the economisers. The details of the machinery in the pump-house will be gathered from Figs. 9 and 10.

Digitized by Google

Steam and Exhaust Pipes.

The usual method of arranging the main steam-pipe in a ring has been departed from in this station, and the engineer endeavoured to reduce the chance of accidents to a minimum by making all the parts of ample section. The main steam-pipe is of Siemens-Martin steel, 10in. diameter, with steel flanges screwed on, faced and bolted. It is carried on cast-iron brackets on rollers, so that any expansion does not produce strains at the points of support. The branch connections to the boilers and engines are of the same type, and are 6in. diameter inside. The main exhaust-pipe is of cast iron, 12in. diameter inside. The water-main which supplies the condensers is also of cast iron, and is 18in. diameter, the branch pipes being 3½in. diameter. The discharge-pipe carrying away the water and condensed steam from the Korting condensers is 12in. diameter, leading into a 15in. sewer.

The condensing water is obtained from the river, and is pumped up into the tank (shown in Fig. 9) by two electric pumps, by Gwynne and Co., and a steam pump, by Pearn and Co. Three Korting ejector condensers are provided for each engine.

The Engines.

There are three engines of the horizontal, coupled, compound type by Marshall, Sons, and Co., each with high-pressure cylinder 11in. diameter, low-pressure cylinder 19in. diameter, both 26in. stroke. The cylinders are steam-jacketed, the inner barrel being cast separately of a special hard mixture of iron, and tightly forced into the main casting of the cylinder. The clearances are carefully worked out, and the inside faces of the covers and both sides of the pistons are turned and polished to prevent initial condensation. The governors are Dr. Pröell's patent, with two valve-releasing gear and Corliss exhaust-valves, and the governors are chain-driven direct from the crank-shaft.

"AN EXTRAORDINARY CASE."

This was an exclamation of Prof. FitzGerald's as regards the fatal accident on the Portrush electric railway in the beginning of August. A summary of the evidence at the Board of Trade enquiry held by Major Cardew was given by us in our last issue, and it is in the evidence that Prof. FitzGerald's exclamation will be found. We cannot comment upon this evidence till the report of Major Cardew is made public; but there are incidental questions relating to all enquiries of this kind that may well be mentioned. In the first place, accidents, fatal or otherwise, cannot be wholly avoided when there is moving machinery. No matter what precautions are taken, the unforeseen will arise and an accident will happen. This conclusion ought not to prevent us taking all possible precautions to prevent accidents, and no matter whether we are dealing with an electric or any other railway, "prevention is better than cure." One great difficulty in the way of prevention is that we do not always know what to prevent. The state of our knowledge at the present day would prevent a second Portrush electric tramway being built, but the state of our knowledge now is not what it was ten or twelve years ago, nor what it will be ten or twelve years hence. No doubt the work of to-day will twelve years hence be reckoned defective, even as we look upon the work of twelve years ago as defective. Are we to stop the work of to-day because of the further information the future will bring forth? The Portrush railway was built years ago. It was compulsorily a cheap line, otherwise there was no prospect of return for outlay. The ordinary engineering mind would agree to the formula, take every known precaution for the prevention of accidents at the time of constructing the machinery. There seems to be no possible objection to that course. There is, however, a much greater and much weightier question behind. Is a railway or a tramway, which has complied with all the rules and regulations in force at the time of construction, to be compelled to carry out every change indicated by advance in knowledge? It is usual to erect the best machine known at the moment and to continue to use that machine as long as possible, even though progress is made in that particular class of machinery and better machines are in the market before the original is worn out. Capital can hardly be limited if change is continuous—and in all directions change is continuous. Facing points are not obsolete, interlocking signals are not everywhere found on railways, but the old designs are not all replaced by newer designs. Our point, in fact, is this: you cannot utterly condemn something that is convenient because progress has rendered it somewhat old-fashioned and knowledge has shown it has weak points tending to accidents. We must not be taken to say the Portrush tramway is dangerous. Like Prof. FitzGerald, we say the fatal accident presents "an extraordinary case." Expert evidence here, as in so many other cases, must seem very divergent to the general reader, but the fact is—and every expert fully understands it is so—the conditions surrounding a fatal acci-

Digitized by Google

dent are so complex that it is difficult to say which is the predominant feature leading to the exact result. In this particular case witness after witness came forward to say that boys and girls, workmen and visitors, are often taking shocks, and up to the accident under consideration with no other result than inconvenience. The state of the body, the state of the rails, the state of the earth, the state of the atmosphere, the state of the machinery, the number of cars suddenly put on or off the line, these and many other things have to be considered. A particular combination of circumstances may lead to an accident, but in many cases the combination is extraordinary—could hardly, or not at all, be obtained at will. The expert evidence at the enquiry was of two kinds: on the one hand, that nine animals have been killed; on the other, that people come from a distance to take shocks to try and cure rheumatism.

The extreme pressure upon our space caused by the descriptions of the various central stations just completed, renders it impossible to discuss the interesting material which has appeared in the *Lancet* on death by electric shock. Dr. Shettle, in a long letter which appeared on September 14, rather supported the views of Dr. Bleile, of Ohio, that death was due to the action of the nervous system upon the arteries. Dr. Shettle explained his views, which are founded upon magnetic action, and an editorial appended to his letter traversed the views expressed therein. On September 21 the *Lancet* dealt editorially with the subject, and on September 28 Dr. Shettle replied. We hope to give the whole of this correspondence at an early date, but meanwhile we desire to call attention to the fact that the electrolytic action of the current upon the fluids of the body is by this class of experts absolutely ignored. This again goes to prove, from another point of view, how extraordinary everything connected with fatal electric accidents must appear to the non-technical reader. Of course the coroner and his jury, or the president of an enquiry, have to deal with the fact of death, and have nothing to do with physiological effects; but the time may come when a real knowledge of the latter will simplify all enquiries in this direction.

THE FALLS OF FOYERS.

The following correspondence has taken place between the Duke of Westminster and the British Aluminium Company, Limited, 9, Victoria-street, Westminster, respecting the Falls of Foyers:

"9, Victoria-street, Westminster, S.W., September 19.

"To his Grace the Duke of Westminster, K.G.,

"Grosvenor House, W.

"My Lord Duke,—I am instructed by the directors of this company to write in reference to the letter, dated July 31 last, signed by your grace, and published in the *Times* and other newspapers, which comments upon their proposed works in Scotland.

"The company, considering that they alone had the right to deal with their own property, have hitherto refrained from entering into any controversy in the public Press concerning the works they propose to erect at Foyers; but the great importance that has been given to your grace's letter by its frequent republication and comments in the Press makes it necessary, in the opinion of those who advise the company, that the incorrect statements made therein, founded, no doubt, on improper information given to your grace, should now be publicly corrected. The directors feel sure that it will only be necessary to show to your grace wherein these statements are wrong, to have them corrected in the same public manner as they have been made, and that they are not mistaken in supposing your grace will, after reading this letter, cause these corrections to be made.

"Your grace states that, in connection with the aluminium works which are about to be started at Foyers, great spoil heaps will be created. As a matter of fact, the process to be carried out at Foyers consists only of the electrolytic decomposition of the oxide of aluminium, and consequently there will be no solid or liquid residuum, and no heaps formed which will spoil the beauty of the place. The oxide of aluminium is obtained from the company's mines in Ulster in the form of bauxite, which which is afterwards treated at the company's works at Larne, so as to free it from its impurities.

"Secondly, it is stated in the same letter that the factory there will emit hydrofluoric acid gas, which will be most destructive to the vegetation in the neighbourhood. If this were the case, the only party concerned would be the company, as proprietors of the land for several miles round the site of the factory. In reality, however, no such destructive effect will occur, as your grace's informants could have easily found out by procuring a report as to the state of the vegetation in the neighbourhood of the Continental factories at Schaffhausen and Froges, or by reading the official report on this matter published by the Swiss Government authorities.

"There remains an allegation in your grace's letter to be answered—viz., that the agent of this company has stated that 'the Falls will not be injured, only there will be no water in them.' This statement is untrue, and was not made by any person in the employ of the company.

"The company has never contemplated taking all the water passing over the Falls, or interfering with their natural structure, and such water as the company do not use will pass over the Falls as at present, but should the company's proposals for the storage of the water during flood times not be allowed, the company may reluctantly be compelled to utilise in times of scarcity the whole of the flow.

"The works carried out at Foyers will be very beneficial to the whole district, and consequently the company have received the cordial support of the local authorities and inhabitants. Those who are well acquainted with the neighbourhood recognise that the submergence of the boggy land between Lochs Garth and Farraline, and the creation of one grand loch, will be a distinct improvement to the scenery.

"Your grace will therefore see that the attempt to influence the decision of the County Council is calculated, if successful, to defeat the object your grace has in view—viz., the securing the amenities of the place to those visitors who desire to view the beauties of the Highlands.

"The directors have fully considered the scheme for the production of this metal, and have adopted the only method open to them to secure to this country the benefit resulting from this important industry.

"The directors feel convinced that your grace will, without delay, correct publicly the misleading statements contained in the above-mentioned letter, which are undoubtedly due to misrepresentations made to your grace by persons not possessed of adequate information.—I beg to remain, my Lord Duke, your obedient servant,

"For the British Aluminium Company, Limited.

"CHARLES F. JONES, secretary."

"September 30, 1895.

"Duke of Westminster, Eaton Hall, Chester.

"We wrote your grace on 19th inst., under registered cover, asking for public contradiction of misleading statements made in your letter concerning our business. So far we have received no reply, and, besides, to-day a letter is published by someone connected with your grace in this matter making baseless insinuations against honourable people who have acted straightforwardly and for the good of their district. Unless a thorough retractation is published before next Thursday, October 3, we shall feel compelled to send the whole of the correspondence to the public Press.

"BRITISH ALUMINIUM COMPANY, 9, Victoria-street, S.W."

"Eaton, Chester, Oct. 3, 1895.

"Dear Sir,—I am directed by the Duke of Westminster to acknowledge the receipt of your letter of September 19 with regard to the works that it is proposed to erect at Foyers.

"His grace is afraid that he cannot correct the alleged misstatements in his letter of July 31, and would suggest that the directors of the British Aluminium Company should, if they see fit, publish your letter of September 17 as a reply to his grace.

"I regret that there should have been a delay in replying to your letter, which was sent to me by his grace at a time when I was travelling in Scotland, and which I inadvertently mislaid.

"With many apologies for the consequent apparent want of courtesy, I remain, yours faithfully, "ARTHUR LAWLEY.

"The Secretary, British Aluminium Company."

STAFFORD ELECTRICITY WORKS.

(Concluded from page 421.)

The illustration (Fig. 11) represents a section of a cylinder fitted with Pröell's patent two-valve gear. This gear consists of two equilibrium admission valves, A, one to each end of the cylinder. These are alternately lifted by means of the valve spindle in connection with the principal trip levers, B. These trip levers are depressed by means of the L levers, C, which are connected on opposite ends of the rocking lever worked from the eccentric. The ends, D, of the L levers, projecting towards the centre, are brought into contact at each stroke with the trip pad, E. This trip pad is connected with the governor through the medium of the levers F and G and the shaft, H; and the height of this trip pad determines the moment of cut-off of the steam, for as soon as the end, D, of the L lever reaches the trip pad, any further movement of the rocking lever disengages the L lever from the trip lever, B, and the valve immediately closes. The closing speed of the valve can be very readily regulated by means of the spring box, K, so that although it closes the valve very rapidly, it does it very quietly, thus preventing any undue wear of the valves or faces. All the working parts of this gear are case-hardened, and the cutting-off edges are made of tool steel, hardened. The governor controlling this gear is of a very powerful and sensitive type, and has sufficient range to regulate the cut-off at any point up to five-eighths of the stroke. It can be fitted with a special adjusting arrangement, so that the speed of the engine may be varied 5 per cent. either way whilst the engine is running: this is a point of considerable importance for many classes of work, and enables the speed of the engine to be most accurately adjusted.

The crankshaft and bearings are of extra strength; all the wearing parts are amply large. Brass bushes and neck rings are provided for all rods, with patent metallic packing for the stuffing-boxes, and complete and efficient lubrication is everywhere provided. The flywheels are grooved for rope-driving, and fitted with barring gear. Pillars with hand-rails are placed round the discs, connecting-rods, and flywheels, and the engines throughout are fitted up in the first-class style for which this firm is renowned. With each engine is provided a Korting condenser with non-return valve, but the engines are so arranged that they may be worked either condensing or non-condensing. The condensers are fed by an overhead tank, which is supplied with water from the river by two electromotor

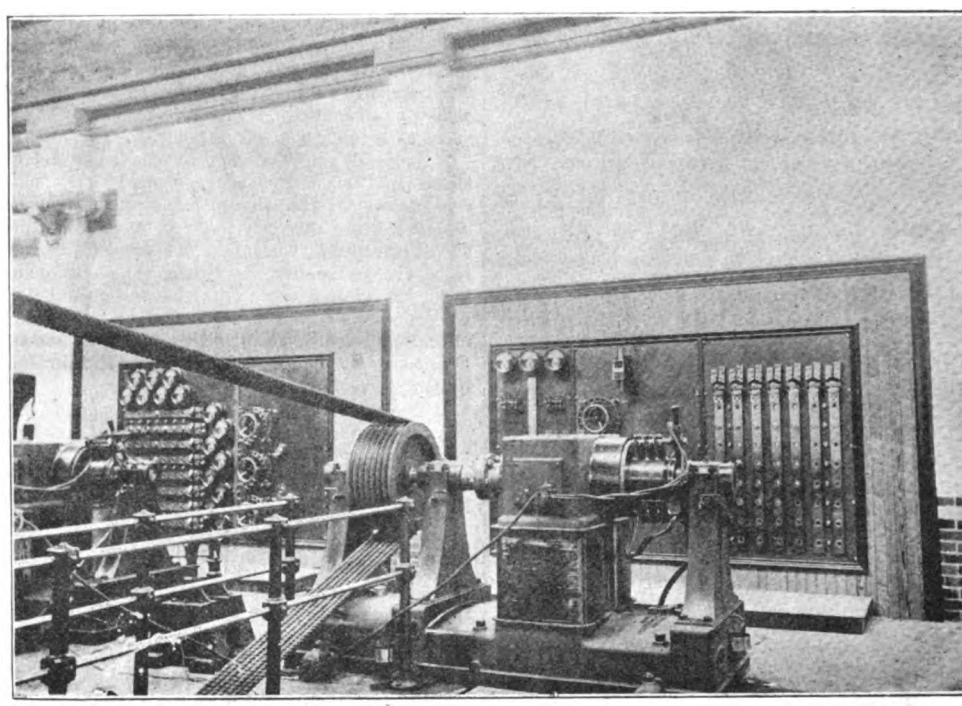

FIG. 15.—View of the E.C.C. 66-K.W. Dynamos and Switchboards.

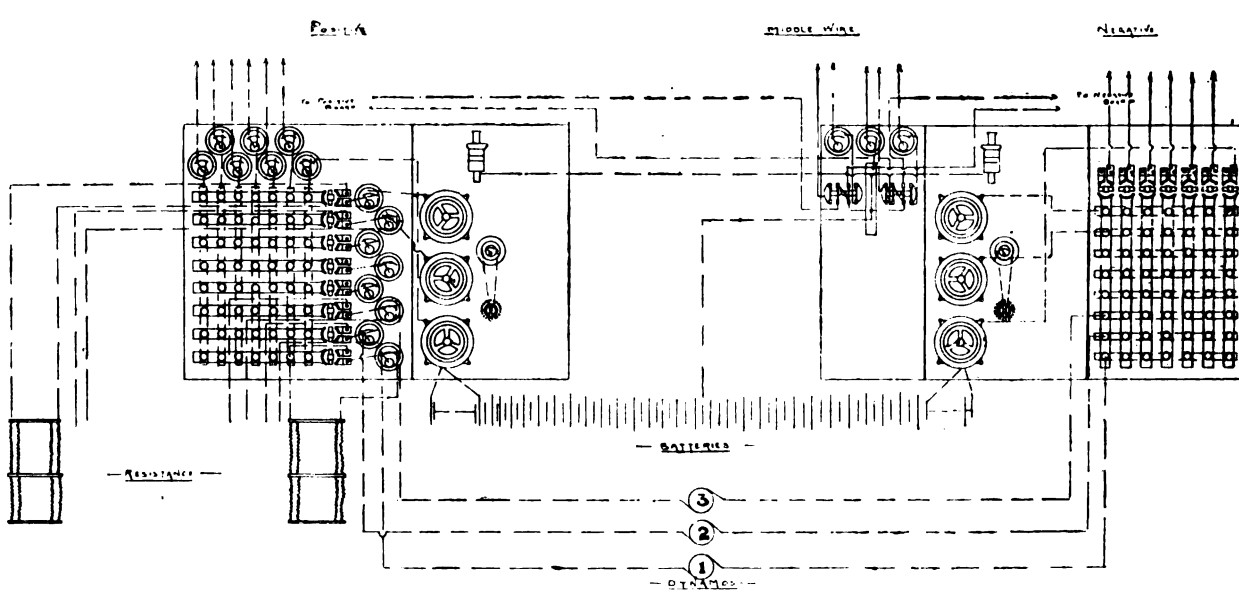

FIG. 16.—Stafford Switchboards and Connections.

Digitized by Google

pumps and one tandem compound plunger steam-pump of the Cameron type; this latter pump is also condensing in the same manner as the engines.

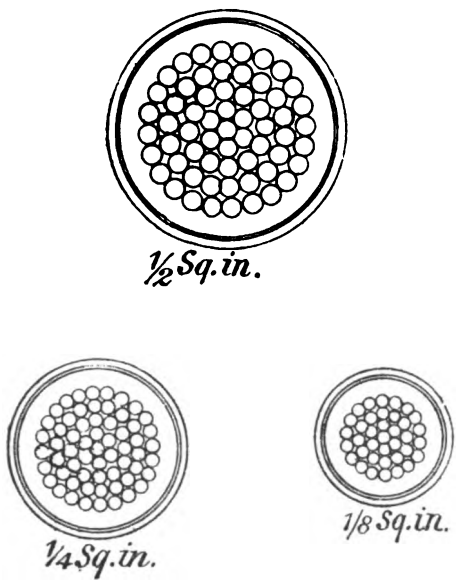

FIG. 17.—Full-size Sections of Siemens Cables.

Each engine is capable of delivering 90 b.h.p. to the ropes which drive the dynamos. The steam-consumption dynamo machine fully loaded so as to receive about 90 h.p., and will then be indicated from time to time and the mean value taken. The engine will afterwards be run with its dynamo machine light, and the engine will be again indicated. The difference between the two indicated horse-powers shall be taken as the net power of the engine. The steam supplied during four hours or thereabouts to the engine and jackets will be determined. If the water used is less than 21lb. per net horse-power per hour, the Corporation will pay to the contractor in respect of each engine at the rate of £20 for every pound by which this water is less than 21lb. If the water used is more than 21lb., a sum, at the rate of £20 for every pound by which the water is more than 21lb., is to be deducted from any sum or sums due or which may become due to the contractor in respect of each engine.

The general view of the engines in position is shown in Fig. 3, while Figs. 12, 13, and 14 give the details of construction.

DYNAMOS.

These are driven by the engines by means of seven 1⅛in. ropes. The three dynamos were manufactured by the Electric Construction Corporation, and are shunt wound. There are three E. C. C. shunt-wound dynamos, Fig. 15, each giving an output of 300 amperes, 220 volts, running at a speed of 600 revolutions per minute. Each machine is fitted with three bearings, and the armature is driven by a rope pulley. The top half of the magnet is arranged to lift off, so that the armature may be removed without upsetting the bearings. When completed, the following tests

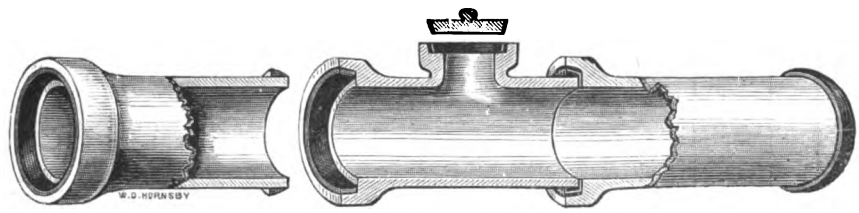

FIG. 18.—Details of Stanford's Patent Joint.

trials in accordance with the specification have yet to be made, but Marshall, Sons, and Co. are confident that these designs will win premiums. The conditions of trial and bonuses will be as follow: The engine will be run with its dynamo machine fully loaded so as to receive about 90 h.p., and will then be indicated from time to time and the mean value taken. The engine will afterwards be run with its dynamo machine light, and the engine will be again indicated. The difference between the two indicated horse-powers shall be taken as the net power of the engine. The steam supplied during four hours or thereabouts to the engine and jackets will be determined. If the water used is less than 21lb. per net horse-power per hour, the Corporation will pay to the contractor in respect of each engine at the rate of £20 for every pound by which this water is less than 21lb. If the water used is more than 21lb., a sum, at the rate of £20 for every pound by which the water is more than 21lb., is to be deducted from any sum or sums due or which may become due to the contractor in respect of each engine.

The general view of the engines in position is shown in Fig. 3, while Figs. 12, 13, and 14 give the details of construction.

DYNAMOS.

These are driven by the engines by means of seven 1⅛in. ropes. The three dynamos were manufactured by the Electric Construction Corporation, and are shunt wound. There are three E. C. C. shunt-wound dynamos, Fig. 15, each giving an output of 300 amperes, 220 volts, running at a speed of 600 revolutions per minute. Each machine is fitted with three bearings, and the armature is driven by a rope pulley. The top half of the magnet is arranged to lift off, so that the armature may be removed without upsetting the bearings. When completed, the following tests were made of two of these machines by Dr. Hopkinson: Two machines selected were coupled together—the one providing current to drive the other as a motor, the latter the mechanical power to drive the former. The magnets

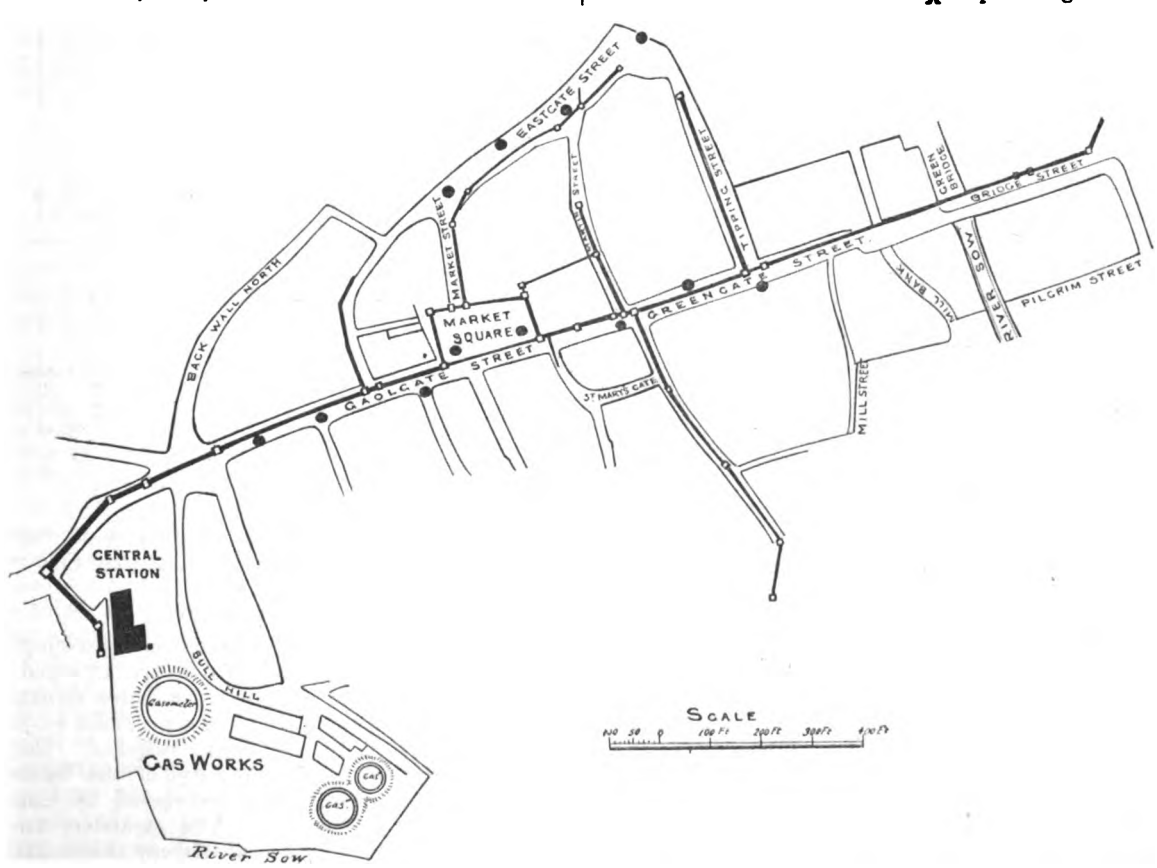

FIG. 19.—Plan of Mains now Laid at Stafford. • denotes Proposed Arc Lamps

Digitized by Google

were separately excited with the appropriate currents. In series with the armatures of the two machines, a third machine was coupled to give the excess of potential required by the motor above that given by the generator. The various parts of the combination were so adjusted that the generator gave a current of not less than 300 amperes at 220 volts at a speed not greater than 600 revolutions. The whole combination was run under these conditions for six hours without sensible sparking, without excessive heating, and without developing any defect in either machine. During the last two hours of the run the following test of efficiency was made: The potential difference between the brushes of the motor and the current passing through the machines was measured. To the product of them was added the power in watts used in the magnets of the motor, the sum being the power supplied to the motor. The difference of the potential differences of the motor and generator was measured, and this subtracted from the potential of the motor gave the potential difference of the generator. From the product of this potential difference and the current passing was deducted the power in watts used in the magnets of the generator, and the difference gave the power of the generator. The ratio of the power of the generator to the power of the motor reckoned as a percentage is then the efficiency of the combination.

The guaranteed combined efficiency of the two machines was 84 per cent., and the Corporation offered £30 bonus for every 1 per cent. by which this combined efficiency was exceeded. On the trial referred to Dr. John Hopkinson obtained an efficiency of 88·1 per cent. for the combined set. Thus the total bonus of £122 was awarded to the makers. The average efficiency of each machine thus works out at 93·9 per cent.

Batteries.

The batteries consist of 112 Chloride cells. The cells are of the company's specially protected type, and contain 29 plates in each cell, mounted upon glass suspension plates, and fitted in wood boxes lead-lined. The special protection with which these cells are fitted is a speciality of the Chloride Company's, and consists in each positive plate being encased in a sheet of asbestos cloth, with separators between the positive and negative plates. Provision is made for the free circulation of the electrolyte, and the active material is at the same time held in position. The output of the battery varies with the rate of discharge as follows: It will give 294 amperes for three hours = 882 ampere-hours; or 182 amperes for six hours = 1,092 ampere-hours; or 140 amperes for nine hours = 1,260 ampere-hours; 112 amperes for 12 hours = 1,344 ampere-hours. Owing to the high capacity of the Chloride plates, the space occupied by the battery is claimed by the makers to be some 40 per cent. less than that required for other types.

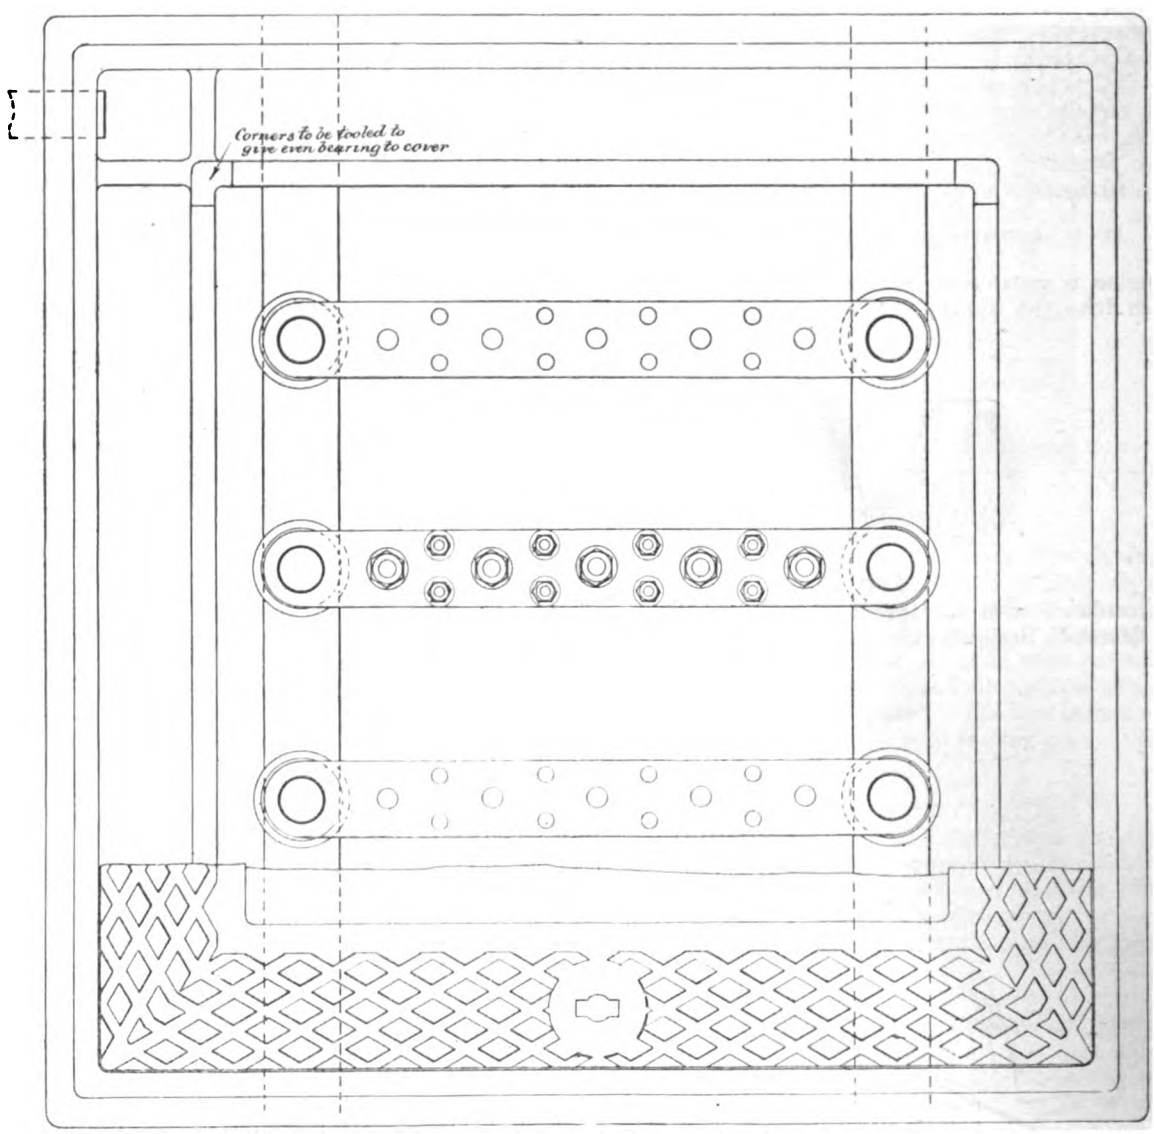

Fig. 20.—Plan of Distributing-box.

Switchboard.

The Electric Construction Corporation also supplied the main switchboards, Fig. 16, which are arranged on the three-wire system for coupling the three dynamos and accumulators on to any one of the six circuits by means of screw-plug connections and main switches. Regulating switches for the charge and discharge of the batteries are provided, the sparking being prevented by means of a resistance across each contact. The ammeters are of the well-known E. C. C. pattern, Kelvin electrostatic voltmeters being also provided. The boards are divided into five panels, supported on wrought-iron frames, and finished off with polished wood moulding.

The interesting feature in this switchboard is the scarcity

Digitized by Google

of voltmeters and the absence of pilot wires, with their usual attachments. Thus there are 18 ammeters used and only two voltmeters. The details of connection are as follow: On the negative board the dynamo and battery bars are horizontal, and are placed behind the board (Fig. 15), while the feeder bars are vertical, and are placed on the surface of the slab. The plugs connecting through from one bar to the other are constructed as follow: The end of the plug is screwed, and then the screw is cut away at two sides. The screwed hole is also cut away, so that the plug can be inserted to the full depth at once. Then a quarter turn causes the remaining portions of the screw to engage, and to tighten the front portion of the plug against the front bar. This construction enables connections to be made quickly, but the contact obtained is not so good as with the ground-in-plug type. On the positive section of the board the dynamo and accumulator bars are horizontal, and are on the face of the slab, while the feeder bars are vertical and are placed behind.

It will be noticed that the switches connecting the machines and batteries to their respective bars have two contacts. When the switch is on the first a resistance is in the circuit. On the ammeter there are small indicators showing the direction of the current, which are of use when paralleling the dynamos, etc. For instance, when a fresh dynamo is to be switched, there are no means provided for finding its E.M.F.; but as it is first inserted with resistance in series, this small indicator shows which way the current flows, thus showing what regulation is required. When this is correctly done, the indicator goes back to zero and the machine is switched in light. The same applies to the feeders, but it is not clear how the man in charge will ascertain the voltage at the far end of the network.

Mains.

The whole of the feeders and distributing network have been supplied and laid by Messrs. Siemens Bros. and Co. The cable is of the usual type manufactured by that firm, and consists of copper conductors having sectional areas varying from $\frac{1}{8}$ and $\frac{1}{4}$ up to $\frac{1}{2}$ square inch. They are insulated with pure and vulcanised rubber, then taped and braided over all. The braiding colour is varied to distinguish the positive, negative, and middle conductors from each other. The full-size sections of these cables are shown in Fig. 17. The cables are drawn into earthenware pipes, supplied by Doulton and Co., from brickwork distributing boxes. The $\frac{1}{2}$ square inch cables, and some of the $\frac{1}{4}$ square inch cables, are used as feeders, and are placed in 6in. pipes, while the distributing network is placed in 4in. piping, and consists of two cables of $\frac{1}{4}$ square inch sectional area and a middle wire of $\frac{1}{8}$ square inch area. The insulation of the cable is 2,500 megohms per statute mile when tested with an E.M.F. of 300 volts. The earthenware pipes are connected together by means of Stanford's patent joint, Fig. 18. In this invention a tight joint is obtainable by casting upon the spigot and in the socket of each pipe, by means of moulds prepared for the purpose, rings of cheap and durable material, which when put together fit mechanically into each other; and by making these rings of a spherical form, a certain amount of movement or settlement may take place without destroying the accuracy of the joint. When laying these pipes, therefore, all that is necessary is to insert the spigot of one fairly and firmly into the socket of another previously laid, the joint surfaces having previously been smeared with some kind of grease; the joint is then complete. In this way a joint is obtained that entails the least disturbance of the ground, and that does not necessitate the absolute drying of the trench bottom when it is being made. At Stafford the pipes entering the distributing boxes are formed with bell-mouths to facilitate the drawing in of the cables.

A map of the district in which mains are already laid is shown in Fig. 19. The circles in the street denote the position of arc lamps in a scheme for street-lighting now under consideration. Figs. 20 and 21 show details of the distributing boxes, which were designed by Dr. Hopkinson. The copper omnibus bars are supported on oil insulators attached to galvanised iron bars built into the brickwork of the box. The method of draining the cover frame is well arranged so that no moisture can get into the box.

Charges.

The committee have authorised a charge of 8d. per Board of Trade unit for all electricity used up to a maximum demand of $1\frac{1}{2}$ hours per day, and all units consumed above this quantity will be charged at 4d. per Board of Trade unit. Upon each consumer's premises there is fixed one of Wright's patent demand indicators. This plan recommended itself as the fairest and most equitable basis upon which to charge for electricity, both to the supply company and the consumer.

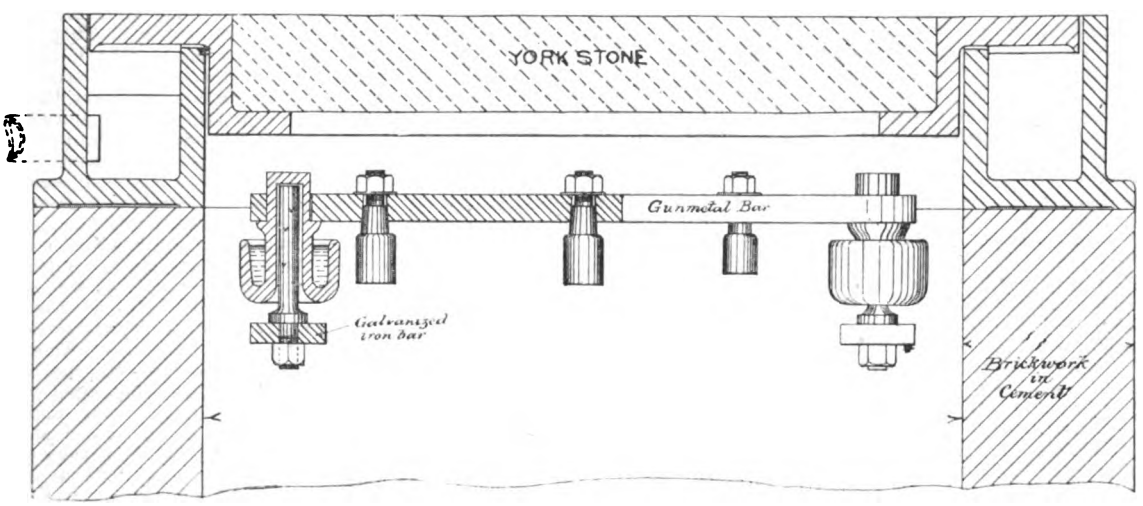

Fig. 21.—Section of Distributing-box.

Mr. Bell, who has had so much to do with the design and erection of the station, will be responsible for its running, and has appointed Mr. J. S. Highfield to be electrical engineer-in-charge.

We must congratulate the Electric Lighting Committee and their chairman, Mr. W. H. Peach, on the success which has followed their efforts to provide a thoroughly efficient electric lighting equipment for their fellow-townsmen.

Contracts Open.—Tenders are invited for the electric lighting of Miners' Hall, Ashington. Apply to Messrs. Boolds and Hardy, Morpeth.—The Bolton Union require tenders for the installation of the electric light at the Poor-Law Offices, Mawdsley-street. Tenders by 15th inst. to, and conditions from, Mr. Simpson Cooper, union clerk, 28, Mawdsley-street, Bolton.

Birmingham.—The lighting and distribution of power at the new technical school in Suffolk-street is done throughout by electricity. The engineering of the installation was placed in the hands of Messrs. Henry Lea and Thornbery, of Bennett's-hill, Birmingham, upon whose specifications and plans tenders were obtained, and who supervised the work after the order had been placed with Messrs. B. Verity and Sons, of London and Birmingham. The first instructions were given to the contractors about the end of May last, and the light was used for school purposes on September 16, and has since then been nightly in use without interruption. There are in all about 806 incandescent lamps and 80 arc lamps.

LEGAL INTELLIGENCE.

PINK v. CAMBRIDGE ELECTRIC SUPPLY COMPANY, LIMITED.

In this case in the Cambridge County Court, Mr. Octavius Frank Pink, chief assistant in the Cambridge Free Library, was the plaintiff, and Mr. W. Cockerell (instructed by Mr. H. C. Squires) appeared on his behalf. The defendants were the Cambridge Electric Supply Company, Limited, for whom Dr. Cooper (instructed by Messrs. Ginn and Matthew) appeared. The case was tried before a jury.

Mr. Cockerell, in opening the case, said the action was brought to recover damages for an accident which, he contended, was due to the negligent work of the electric supply company in connection with the laying down of the company's plant. A clause in the provisional order, which was confirmed by the Act of 1890, made the company answerable for all accidents or injuries happening through the fault of anyone in its employ.

Mr. Pink said that about 9.30 on the night of the 27th of May last he was walking from the free library in the direction of Market hill, and when near Messrs. Hallack and Bond's shop the inside of his right heel caught against one of the "electric light boxes." It was a moderately light night, and he was walking at the rate of about three miles an hour. He was thrown heavily to the ground. When he got up he examined the box and found it at least ½in. above the level of the pavement. The box was not so high now as then. He was injured by the fall just below the knee-cap, and he was unable to walk the next day. The injury gave him great pain for three weeks, and he was not able to walk as before until about the end of July. If he had been able to go to London on May 28 he would have realised a profit of at least £2. 5s. in the purchase of a book.

Mr. Wherry, surgeon, said the plaintiff consulted him on the 30th of May. Mr. Pink had a torn wound across the right knee-cap, which was swollen, and witness advised him not to stand more than necessary. A month or six weeks would elapse ere Mr. Pink was able to walk as before.

Dr. Cooper, on behalf of the defendants, submitted that the accident occurred through Mr. Pink's own want of caution. The box was now in the same position as on May 27. The defendants were only responsible for any accident that might have occurred in consequence of the boxes being improperly laid down. The Corporation repaired the pavement, and it was the duty of the Corporation to keep the pavement at such a height that the boxes should not be above it If, however, the company was liable, he submitted that the claim for damages was a most exorbitant one.

Mr. John Henry Barker said he had been manager of the defendant company since June, 1893, and to his knowledge the box in question had not been moved since then. The day after Mr. Pink's claim was made instructions were given that the box should not be moved until the claim had been settled. If the pavement near any box was irregular the company notified the Corporation of the fact, and the Corporation had, from time to time, repaired the pavement, and no account in respect of the work had been sent to the company. The lid of the box in question was taken up last Christmas, but afterwards screwed down again to its former position.

Francis Gerald Holder said he examined the box in December last and found it all right.

Alfred Cole said he inspected the box in March last and entered the word "right" in his pocket-book. That entry meant that the box was level with the pavement.

George Arnott, wireman, in the employ of the company, said the box was now in the same position as on March 25.

This concluded the case for the defence, and his Honour and the jury afterwards viewed the box. On the Court resuming, **Mr. Cockerell** addressed the jury for the plaintiff.

His Honour, in summing up, asked the jury to answer the following questions: Was the box as originally laid down level with the pavement so as not to be a source of danger on account of inequality of surface; has the level of the box or any corner of it been raised since originally laid down; if it has been raised, was it raised so as to be a source of danger, in consequence of inequality of surface; if there was such inequality, was it the cause of the accident; was there any contributory negligence on the part of the plaintiff; and what, if any, damages are due to the plaintiff? His Honour added that he did not see the slightest trace of contributory negligence.

The jury found a verdict for the defendants, and judgment was entered for them with costs.

WESTERN ELECTRIC COMPANY v. BRUSH ELECTRIC COMPANY.

In the suit of Western Electric Company *v.* Brush Electric Company on patent No. 476,317, issued to C. H. Rudd, June 7, 1892, for a system of testing electric circuits, a final decree was entered on September 17 by Judge Showalter, of the United States Court, finding the patent valid, and infringed by the Brush Electric Company. The patent in question covers a system of locating grounds and other troubles on an electric light circuit, which consists in providing an artificial circuit of high resistance at the station, and adapted to be connected to a line circuit, the resistance of the artificial circuit being fixed and so apportioned between contact points that the attendant, by means of a testing set, may find the neutral point in the artificial circuit corresponding to the neutral point of the line circuit connected therewith. Claim 1 of the patent is as follows: "In an electric light system an artificial circuit containing high resistance of invariable amount, said artificial circuit being connected with the different sides of a dynamo machine while supplying current to a working circuit, said artificial circuit having its resistance apportioned between connecting sockets, in combination with a testing apparatus for determining the neutral point of said artificial circuit, substantially as and for the purpose specified."

COMPANIES' MEETINGS AND REPORTS.

WILLANS AND ROBINSON, LIMITED.

The ordinary general meeting of the shareholders of Willans and Robinson, Limited, took place on the 8th inst. at the Cannon-street Hotel, E.C., Mr. Mark Robinson, chairman of the Company, presiding.

The **Chairman**, in moving the adoption of the report (a copy of which appeared in our last issue), said that he had again to congratulate the shareholders on an encouraging and prosperous half-year. It was true that they had had what he might call a windfall, but even without that the results would have shown an advance on the previous half-year. A portion of that windfall had already been applied to depreciation, but the writing down of assets faster than strict book-keeping required was only another way of adding to the reserve fund. That they had done better in the last half-year was important for two reasons: firstly, they had had to bear the burden of much idle capital which did not at present help to earn dividend, and this must continue so for the next half-year until the Rugby works were completed; and secondly, the first half of the year was seldom, in a business point of view so good as the second. The Board hoped, therefore, that their action in continuing the 7 per cent. dividend would meet with the approval of the shareholders. They might have divided 12 per cent, but they had thought that if they kept up the 7 per cent. dividend during a period of transition, and continued all the time to increase their reserve fund, they would be fulfilling their past promises to the shareholders, and at the same time could give good hope of surpassing them in the future. Turning to the business of the Company, increasing orders must always be a source of congratulation, but these had been somewhat embarrassing to the business as they could not greatly increase their output at Thames Ditton, or, indeed, until the Rugby works were ready. Shareholders would naturally wish to know when that would be. So far as the machine shops were concerned, he did not think they would get tools to work before next spring, but the foundry might be ready before. It had been originally intended to start at Rugby with a large foundry and a small machine shop, the latter being kept subordinate to the one at Thames Ditton, but they had found that this must be reversed, and that Rugby must be the headquarters. Since they contemplated building larger engines they would require heavier tools, and obviously their engines ought from the outset to be erected at the place where the heavy machinery was. Some of the heavier tools would be moved from Ditton, and the larger ones left there would be engaged on repetition work done to template and practically under the supervision of a foreman. The directors were satisfied that at Rugby they would get very efficient shops at a cost which would compare very favourably with Thames Ditton. Their machine shops would be 50 per cent. larger, and their foundry would have an available floor space five or six times greater than at Thames Ditton, so that they would be able themselves to cast all they required instead of as now putting much of it out. Some of the machine tools had been already purchased, and had been set up for the time in an extemporised shop at Ditton. After mentioning that the debenture debt had been paid off and steps taken to also pay off the mortgage on their freehold, the Chairman said that the difficulties in the way of carrying out work on the Continent from here were such that they had thought it better to receive a reasonable rate of royalty from licensees. It was as important as it was difficult to get just the right people to take up business abroad, but as the result of a great deal of negotiation he thought they had got their engines into the hands of people who would do them full justice. He was sorry to say that they had not yet been able to get a Stock Exchange quotation, but the requirements as to the issue and payment up of shares were being complied with, and he believed that all that would be necessary would be for them to renew their application for a quotation in six months' time.

Mr. Erskine seconded the adoption of the report.

Mr. Rose asked if their licensees abroad were bound by the English price list, or allowed to sell at any price they found necessary.

Mr. Bryan Donkin expressed his satisfaction with the report. He looked upon an increasing reserve fund as a patent machine for equalising dividends. He would be glad to hear something as to their new French boiler and the increase in the item for patents.

The **Chairman** said it had been judged necessary to allow their licensees to fix their own prices. They could not, of course, come into competition with the Company in England, the United States, or any country covered by their patents. Any competition, say, in the far East, they looked upon as negligible. They would, of course, receive the royalty upon it, and if any business was done it would rather be additional to than in competition with what they might do themselves. The bulk of the increase under patents was for experimental work on a gas-engine. They had concluded

Digitized by Google

that, had gained valuable information, and whenever they had space and time to take it up they would be able to go on with advantage to the manufacture of gas and oil engines. The particular patent in question they did not propose to take up. The Niclausse boiler promised very well indeed, but it was useless for them to take orders for it which they could not at present execute. It had cost them £5,000, but within a few weeks they had got back £1,000 of that for a sub-license. Some were already at work. They had been obliged to refuse an order from South Africa for seven, and it was understood that the Admiralty had decided to have one of her Majesty's ships fitted with them to try them. Most of their own work at Rugby would be done with the Niclausse boiler. In reply to other shareholders, the Chairman stated that most of their reserve fund was invested in consols. Their work for the Heilmann locomotives was going on satisfactorily, but was not delivered as the locomotives were not ready to receive it.

The report was then carried, as well as the formal motion for the declaration of a 6 per cent. dividend on the preference and a 7 per cent. dividend on the ordinary shares, and the meeting terminated.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Halifax.—Tenders are asked for the laboratory fittings required at the higher grade school, for the Halifax School Board. Particulars may be obtained at the offices of Messrs. Horsfall and Williams, architects, 15, George street, Halifax. Tenders to be delivered before noon on 14th inst.

Madrid.—The Director of Public Works invites tenders by November 15 for the concession of the construction and working of a tramway from Madrid to Colmenar Viejo, with branches to Chamartin and Rosa. Security, 12,505 pesetas. Particulars at the Direccion General de Obras Publicas (Ministerio de Fomento), Madrid.

London, E.C.—The Bengal and North-Western Railway Company, Limited, are prepared to receive tenders by October 16 for the supply of 22 copper tube plates. Specifications, with form of tender and general conditions of contract, may be obtained at the company's offices, 237, Gresham House, Old Broad-street, E.C., upon payment of 10s. each. Tenders must be addressed to Mr. E. L. Marryat, secretary.

Edinburgh.—The Lord Provost, Magistrates, and Council invite tenders for the wiring of the Waverley Market. Specifications and forms of tender can be obtained at the resident electrical engineer's office, 5, Dewar-place, Edinburgh. A deposit of £1 is required, which will be returned on receipt of bona fide tender. Tenders are to be sent to Mr. Thomas Hunter, W.S., town clerk, City Chambers, Edinburgh, endorsed "Tender for Wiring Waverley Market," before 10 a.m. on 12th inst.

Chepping Wycombe (Bucks.).—The Urban Sanitary Authority for this borough are prepared to receive tenders from public companies for working the electric order obtained by them within the borough for a term of years and upon approved conditions. Tenders are to be delivered by noon on October 14 next, at the office of the town clerk, High Wycombe, where a copy of the electric order may be seen and further particulars obtained. The Authority do not bind themselves to accept any tender.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

Killarney.—The Governors invite tenders for the lighting of the district asylum, Killarney, by any kind of illuminant, for 12 months from November 1. Printed forms of tender can be had from the clerk of the asylum on a deposit of £5 being made for each form issued. The deposit will be returned if the tendering be bona fide. Tenders will be received up to 12 noon on 17th inst. The declared contractor will be required to enter into a bond with two securities for the performance of contract.

Brussels.—Tenders are desired for the supply of copper cables and wire (bare and covered) required for the Telegraph Service—first lot, 1,300 to 2,000 metres of house wire with two conductors; 1,200 to 1,300 metres of the same; 300 to 400 metres of twin flexible; 700 to 900 metres of the same; 1,500 to 1 800 metres of the same—caution money, 1,700f.; second lot, 675 to 900 kilos of soft annealed copper wire of 12mm. diameter; 200 to 300 kilos of 16mm. diameter; 300 to 450 kilos of 20mm diameter; 155 000 to 200 000 metres of copper wire, G.P. covered with a layer of white cotton and a braiding of dark cotton; 87,000 to 110,000 metres of the same with a layer of tarred tape; 30,000 to 55,000 metres of the same with an incombustible covering; 2,500 to 3 500 metres of twin flexible—caution money, 3,500f. Particulars at the Administration des Chemins de Fer, des Postes, et des Télégraphes, Brussels. Tenders will be received at the Bourse, Brussels, up to October 16.

RESULTS OF TENDERS.

Blackburn.—The tender of Messrs. B. Verity and Sons, London and Manchester, has been accepted for electric lighting at the Town Hall.

Madras.—The tender of the Brush Electrical Engineering Company for the supply of the whole of the apparatus required for lighting the Arkonam railway station by electricity has been accepted by the board of directors of the Madras Railway.

BUSINESS NOTES.

Eastern Telegraph Company.—The receipts for the month of September show £5,218 increase.

Great Northern Telegraph Company.—For the month of September the receipts were £28,400.

Horsell (Surrey).—The Parish Council have discussed the question of lighting the village by electricity.

Eastern Extension Telegraph Company.—The receipts for the month of September show £12,500 increase.

Orkney.—The County Council have agreed to petition the Government for the extension of the telegraph to Orphir.

Dunfermline.—A correspondence has taken place in the *Dundee Advertiser* on the question of the electric light for Dunfermline.

Llanelly.—The Llanmor (Waddle's) Foundry will shortly be lighted by electricity by Messrs. J. C. Howell, Limited, of Llanelly.

Mile End, E.—The Mile End Vestry have appointed a committee of six to enquire into the advisability of lighting the hamlet by electricity.

Buenos Ayres.—An underground electric tramway is, says a Reuter telegram, about to be constructed in Buenos Ayres. Work will be begun shortly.

Direct Spanish Telegraph Company.—For the month of September the receipts were £2,072, against £1,898 for the corresponding period of 1894.

Halifax.—The Corporation electricity supply is now continuous, night and day. Numerous applications continue to be received for a supply of current for the winter.

Reading.—The Town Council have sanctioned the laying of a number of street mains and the execution of other works by the Reading Electric Supply Company, Limited.

Bury St. Edmunds.—The Town Council have appointed a committee "to consider if it be advisable for the Corporation to light the town by electricity, and by what means."

Western and Brazilian Telegraph Company.—For the week ending October 4 the receipts, after deducting 17 per cent. payable to the Platino-Brazilian Company, were £3,071.

Hampstead.—The Vestry Board-room is now ventilated by means of a Blackman electrical ventilator, which has been fixed in one of the windows under the supervision of the chief electrical engineer.

Godalming.—The Godalming Corporation have decided, by the casting vote of the Mayor, to acquire the waterworks at a cost of £48,000, and to obtain a provisional order for the installation of the electric light.

Worcester.—The Town Council have decided to apply to the Local Government Board to approve of their borrowing £1,300 for wiring the Guildhall and Public Hall for electric lighting, to be repayable in 25 years.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 6th inst. amounted to £1,088, as compared with £908 in the corresponding week of last year, being an increase of £180.

Brierley Hill (Staffs.).—The Urban Council have decided that the clerk be instructed to obtain from electrical engineers of repute information as to the probable cost of lighting the district by electricity in lieu of gas.

Poplar, E.—The Poplar District Board have decided to discharge the reference relating to the notice of the Capital and Counties Electricity Supply Company Limited, of their intention to light the district by electricity.

New Malden (Surrey).—The Urban District Council have decided, with regard to the offer of the Kingston Corporation to extend their electric mains into Coombe, to reply that in their opinion the matter would be premature at present.

Dewsbury.—The contractor for the electric lighting of the Industrial Hall is Mr. G. A. Steinthal, of Bradford. The wiring has been completed both in the hall and in the business premises. There will be about 130 incandescent lamps and two arc lamps.

Newport (Mon.).—Alderman Moses told the Council on Tuesday that the mayor was to be asked to open the central electrical works on Monday next, and at the same time to turn on the supply for the arc lamps which have been placed in the principal streets.

Colliery-Lighting.—Messrs. Clarke and Steavenson, of Lidgett Colliery, Tankersley, near Barnsley, have just electrically lighted the Barrow Hematite Steel Company's collieries, and have installed an 80-h.p. electric coal-cutting plant at the Astley and Tyldesley Collieries, near Manchester.

Killarney.—The annual election of Town Commissioners will take place on the 16th inst. The election will probably be fought on the lighting question again this year, and if candidates are put forward in the interest of gas *versus* electric lighting a close contest, a correspondent says, will be certain.

New Catalogues.—The Electric Construction Company, Limited, have issued a new catalogue, with revised quotations for their standard-size continuous-current dynamos. They invite

Digitized by Google

attention to their speciality in Eickemeyer-wound drum armatures for high voltages, continuous-current transformers and motors.

Whitehaven.—A deputation from the Town Council Water and Lighting Committee have waited upon the Harbour Commissioners, and after a statement and discussion in reference to the electric lighting of the harbour, the deputation intimated that they would communicate further with the Commissioners thereon.

City and South London Railway.—The returns for the week ended October 6 were £887, compared with £892 for the corresponding period of 1894, being a decrease of £5. The total receipts for the half-year 1895 are £11,858, compared with £12,011 for the corresponding period of 1894, being a decrease of £153.

Anglo-American Telegraph.—The directors of the Anglo-American Telegraph Company, Limited, have resolved, after placing £6,000 to the credit of the renewal fund, to declare an interim dividend for the quarter ending September 30 of 10s. per cent. on the ordinary and 20s. per cent. on the preferred stock, less income tax.

Liberian Rubber Syndicate, Limited.—This Company has been registered with a capital of £30,000 in £1 shares Object: to acquire any lands, mines, mining rights, etc., in the republic of Liberia, and to develop and turn to account the same in such manner as the Company shall deem expedient. The directors are Lord Raglan, T. Bower, and C. Woermann.

Newquay (Cornwall)—The gas at Newquay being expensive and not very satisfactory, the directors of the Baths and Laundry Company decided to use electricity for lighting purposes and heating the irons of the mechanical ironers. The installation is now complete, and has been carried out by Messrs. J. S. Cunnington and Co., of 5, John-street, Adelphi, W.C.

Cheltenham.—The chairman of the Lighting Committee of the Corporation reports a gratifying increase in the demand for the electric light. In August the applications amounted to 2,060 8-c.p. lamps; this month they had risen to 3,376, 3,040 of which are actually connected, and are being supplied with the current. The electric lighting station is now running night and day.

Berkhamsted.—Mr. Newman enquired at the Parish Council meeting whether it was likely that they were to have the electric light. In reply, the Chairman said an application was recently made to the District Council, who expressed no objection to the electric light company making an application in the necessary quarter for permission. The District Council did not stand in the way of it.

Removal.—The Epstein Electric Accumulator Company, Limited, late of 215, Gresham House, Old Broad-street, London, E.C., inform us that, owing to the large increase in their business, they have found it necessary to remove their head offices to more commodious premises at Victoria-mansions, 28, Victoria-street, London, S.W., whither all communications in future should be addressed.

Southport.—The Electricity Committee of the Corporation have resolved that on the completion of the present extensions at the electricity works electrical energy be supplied during the whole of the day and night and that the committee placed on record their high appreciation of the ability displayed by Mr. B. J. Wolfenden in the designing and carrying out of the buildings, etc., for the electricity works extensions.

Hull.—A Local Government Board enquiry has been held by Mr. Rienzi Walton, C.E, with reference to the application of the Corporation for permission to borrow £8,000 for purposes of electric lighting. The amount is required to meet the requirements necessitated by the increased demand for the light. Mr. A. S. Barnard, of Lancaster, has been elected to the post of electrical engineer to the Hull Corporation.

Mevagissey (Cornwall).—The Parish Council have received the report of the Electric Light Committee, which showed that the scheme for forming a company was meeting with scant success. Messrs. Veale and Co., of St. Austell, had promised to take £300 worth of shares, and £250 had been promised by people of the town towards the £1,300 required to float the company. The Council decided to give the committee a month more to continue their labours.

Aberdeen.—The Town Council have referred to the Gas and Electric Lighting Committee a letter from the Building Committee of Free Bon-Accord Church to the effect that the committee had been considering the propriety of introducing electric lighting in the new church on the Viaduct, and they wished to know whether, in the event of their seeing their way to do so, the Town Council would extend the mains as far as would permit a supply of the illuminant being given for the new building.

Burton-on-Trent.—In moving the adoption of the report of the Gas and Electric Lighting Committee of the Town Council, Alderman Lowe mentioned that they had agreed to illuminate the parish church clock free of charge. They had also had under consideration the advisableness of using the electric light in the streets in which the cables were laid, but after receiving a report from the manager (Mr. Ramsden) they came to the conclusion that it would be best to postpone further consideration for a time.

Tunbridge Wells.—Councillor Wood has moved the adoption of the Corporation Lighting Committee's report, which showed that the electric system was now in use over a large part of the borough, and that applications for the new light came from all quarters. Alderman Cronk expressed the hope that at the end of such streets as Church-road and York-road the gas lamps would be lit as well as the electric lights, so that a light might be thrown along the side streets. The committee undertook to consider the points raised, the Mayor touching upon the numerous advantages of the electric light over gas in the streets.

Wakefield.—The Electric Lighting Committee have been making steady progress with the proposed electric lighting works for the city. They have tenders for the works, and they hope before very long to have everything in order pending the decision of the Local Government Board as to borrowing powers. It is understood that there is a necessity for pushing on with the work, because some large customers are waiting who, if the Corporation did not provide them with the electric light, would probably supply themselves.

Appointment Vacant.—The Blackburn Corporation are prepared to receive applications for the appointment of assistant engineer at the electricity works. Applicants must have had experience in similar situations in both high and low tension stations. Salary, £130 per annum. Applications, endorsed "Assistant Electrical Engineer," stating age and experience, and accompanied by not less than three testimonials of recent date, to be sent to Mr. Robert E. Fox, town clerk, Town Hall, Blackburn, not later than 19th inst.

New Catalogue.—The United Asbestos Company, Limited, of Billiter-street, London, E.C., send us a copy of their new illustrated catalogue, which is claimed to be the most complete issued in the asbestos trade. The special features therein are their "Victor" metallic joints. "Salamander" joints, "Gladiator" packing, and particularly their new asbestos patented "Salamander" embossed decorations, which are said to be an entirely novel adaptation of asbestos, and likely to prove efficacious in preventing the inception and spread of fire wherever used, either in saloons of vessels or in buildings.

Bradford.—The half-yearly statement as to the profits of the Corporation's gas and electricity works shows that the capital account for electricity works was £67,111, and the income for the year £6 185. The expenditure had been £3,008, the trade profit was £3,176, interest and sinking fund had absorbed £2,190, and the net profit was £986, as compared with £2,138 for the preceding year. The electricity department consider they have been handicapped by their boilers, and the fact that the new engines and plant had not been delivered, but the works are thought to be in a fair way of becoming an appreciable source of income.

St. Albans.—The Town Council have considered an application from the Bedford Electric Light Company, Limited, for the consent of the Council to a proposed application by the company to the Board of Trade, under the Electric Lighting Acts, 1882 to 1888, for a provisional order to authorise the introduction of the electric light into the city of St. Albans. It was decided, on the proposal of Councillor Bowden, seconded by Councillor Watts, that the consent of the Council to the proposed application could not be granted, both mentioning that the subject had been thoroughly gone into on a previous occasion. There were weighty reasons why the application should not be entertained.

Durham—The Postmaster-General has written acknowledging receipt of the letter of the clerk to the Durham Rural District Council as to telegraph extension at Kelloe, and enclosing draft agreement for approval by the Council. The clerk read the draft agreement, which was to the effect that if in any 12 months succeeding the laying on of the telegraphic connection to Kelloe the gross receipts should be less than £31, the guarantors and their successors shall within 14 days pay such a sum of money as altogether, with the gross receipts for telegrams, should make up the £31, and any sum in excess of that shall be taken into account for the subsequent year; also that the occupancy be terminable by the Postmaster.

Leeds.—On Wednesday, as an amendment to the motion of Alderman Sir E. Gaunt, proposing the confirmation of the minutes of the Corporation Property Committee, Mr. J. F. Carter moved that the portion of the minutes containing a resolution in favour of the sale of the whole of the electric lighting plant be referred back to the committee. Mr. Denison seconded the amendment, which, after considerable discussion, was lost. Mr. John Gordon then moved that all the plant be sold, with the exception of one gas-engine. He thought one engine should be retained until arrangements could be made for a hydraulic apparatus to work the hoist to the free library. Alderman Sir E. Gaunt seconded this amendment, which was carried.

Glasgow.—Anent the proposed electric traction, a correspondent writes to a local paper: "I had an opportunity recently of being in Brussels, and I cannot see why anyone can say that the trolley-wire system there is a disfigurement to the streets. The cars work with remarkable smoothness and no noise, and it surprised me to think that we in Glasgow should be so far behind the times with our horse cars, when here was a system that would suit us exactly. The sooner we have electric traction on the cars the better." Mr. Nelson has given notice to call the Police Commissioners' attention to the manner in which Glasgow is lighted with the electric light. He considered that the city was the worst-lighted city in Europe.

Bangor (N.W.)—The Bangor City Council resolved on Wednesday to apply to the Board of Trade for a license to supply electricity within the limits of the borough, and such parts, if any, of the parishes of Llandegai and Pentir as may be thought desirable; and to apply for a provisional order at the earliest opportunity. The minutes of the Electric Lighting Committee of the Council, which were adopted, included a recommendation that Mr. Medhurst be appointed electrical engineer (providing the Council obtain the necessary powers to proceed with the scheme) at a remuneration of £650. If, however, the Council deem it prudent not to proceed further than to obtain the necessary power to

Digitized by Google

proceed, that Mr. Medhurst be paid £50 in full discharge of all claims.

Eastbourne.—The Telephone Sub-Committee of the Town Council have submitted for consideration a further extension of the borough private service of telephonic communication by the installing of wall-box speaking instruments and fire-calls, to be placed as follow, the amount denoting the cost of purchase and fittings: (1) The Shelters, Grand-parade, £32. 9s.; (2) opposite the gates of Ocklynge Cemetery, £45. 7s.; (3) Seaside road, opposite Royal-parade, £26. 13s.; (4) at Gearnip (end of parish), £34. 10s.; (5) chief constable's private house, £31. 19s.; (6) Devonshire Park, £21. 16s. The committee resolved that by way of experiment a telephone wall-box and connection be constructed from the police station to the Parade.

Enfield.—The Enfield District Council have received a letter from the Town and Village Electric Light and Power Company, stating that the terms of their business were so arranged that the revenue obtainable from the plant it supplies covers the cost of both installation and maintenance. The company offered, on receipt of information as to requirements of the Council, to send a *pro formâ* tender and demonstrate how the results mentioned could be attained. Mr. Medhurst wrote offering the Council his services as consulting electrical engineer; Mr. Theodore Ellis of Enfield, wrote asking the Council to give permission for a number of inhabitants to obtain a provisional order, and all these communications were referred to the General Purposes Committee.

Alderley Edge (Cheshire)—A sub-committee have reported to the District Council that they had had an interview with Mr. Clirehugh, electrical engineer, of Manchester, in reference to the purchase of the electric lighting provisional order. Mr. W. G Groves said a draft agreement had been drawn up and clauses had been inserted safeguarding the interests of the Council. He would move that the Council enter into an agreement upon terms satisfactory to the Council. The motion was carried. Dr. Burghardt said that if the Council sold this provisional order, and if they had to wait some time, they would be in an awkward position. They would have to pay the bill of £272 for the order they had received. In the end the Council decided to call another meeting to further consider the electric lighting question.

Belfast.—The Electric Committee of the Corporation have met, under the chairmanship of Alderman Pirrie, J.P. The engineer (Mr. V. A H. M'Cowen) submitted a report on the proposed extension of mains in Arthur-street, Howard-street, College-square North, College square East, and Wellington-place, together with the estimates as to the probable cost, and he was authorised to proceed with the extensions. Tenders for the supply of additional engines and dynamos in the central station were submitted to the town clerk and referred to the engineer for a report. The building at Larne for the British Aluminium Company is rapidly approaching completion. The machinery is being supplied by Messrs. Victor Coates and Co., of Prince's Dock Foundry, Belfast. The cost of the erection will be, it is stated, £16,000.

Dover.—The Town Council have received a letter from the electric supply company, enclosing plans showing the proposed position of the arc lights in Snargate-street, and stating that sanction had been obtained in all cases except one. Councillor G. Mowll said he did not think the chairman knew of the way in which the electric light company's servants carried on the work. He referred to the dangerous manner in which the transformer-chambers were left open with often no cage on them. He asked on whom the responsibility would fall if someone fell down, an accident which, according to Councillor Thorpe, had already occurred. Two alternative proposals for the alteration of the arc lamps from the Monument to the Market-square were also forwarded by the electric lighting company, and referred to the Town Ward Committee.

A Bankers' Strong-room, weighing upwards of 20 tons, and valued at £1,000, has been completed this week at the works, in Wolverhampton, of George Price, Limited, bankers' engineers. The room has been specially constructed for Messrs. Beckett and Co., bankers, Leeds, and is claimed to be one of the largest, heaviest, and most scientifically constructed strong-rooms ever turned out in the Midlands. It is 15ft. 3in. long, 11ft. 3in. wide, and 12ft. 3in. high, and is composed of plates, case-hardened all over, and absolutely drill, burglar, and fire proof. The door-plate is 2in. solid case-hardened metal over the lock, and the door, together with the inner gate, weighs two tons. At the rear of the door is an electric alarm, which communicates with the manager's room, and which rings when the door is opened. The interior is to be fitted up with electric lights.

Barnet—A resolution in Mr. Bampfield's name at the Urban Council's meeting was as follows: "That the Council consider at once the best method of dealing with the question of electric lighting so as to satisfy the requirements of the provisional order." The General Purposes Committee, he said, had been considering the whole question of electric lighting without any instructions from the Council, and he was afraid lest the matter might be rushed through without full consideration. He complained, also, that the new members of the Council (as distinguished from members of the Local Board) were not represented upon the committee, although they were returned, with the aid of the Ratepayers' Association, to oppose any undue haste in bringing the electric light into the town. For the motion there voted only the proposer, and it was therefore rejected.

New Issue.—The Salt Lake and Ogden Gas and Electric Light Company, Limited, announce the issue of 100,000 shares, part of 150,000 5 per cent. cumulative preference shares of £1 each. The company was formed in 1893, with a share capital of 1,500,000dol., for the purpose of acquiring the franchises extending to the year 1918 and consolidating the several undertakings previously carried on in Salt Lake City and Ogden for the supply of gas and electric light and power in both these cities. That company created an issue of 1,500 000dol. (£300,000) 6 per cent. first mortgage gold bonds, specially secured by a registered mortgage in favour of the Farmers' Loan and Trust Company of New York, as trustees upon the consolidated properties, whereof 1,250,000dol. (£250,000) have been issued, and the interest regularly paid.

Hammersmith—Tenders for the electric lighting installation have been received by the Hammersmith Vestry from several firms, and are now before a sub-committee. The Electric Lighting Committee reported that, having considered the circular letter from the City of London Electric Lighting Company, referring to a recent case in the Court of Appeal, stating that it was intended to convene a meeting to determine upon a course of action with the object of obtaining an amendment of the law that will give reasonable protection to undertakers and at the same time secure full compensation to all persons and bodies interested for all damage caused by the user of any electric light works, they were advised that this object would be attained were a general Act of Parliament passed containing a clause in the form they proposed. The Vestry decided to send the chairman and vice-chairman to the meeting as delegates.

Ladders for Electric Light Work.—The great difficulty of using ladders upon wheeled carriages in uneven roadways and upon hillsides has now, it is claimed, been overcome by Mr. Heathman's recent improvements, and the Heathman patent telescopic ladders recently sent to Ealing, Tunbridge, Bray, and Taunton installations for recarboning the street arc lamps are said to be adjustable quite perpendicular even when one side of the carriage is in a deep gutter or upon a high pavement. In addition to which it is stated that the ladders can swing to any angle of inclination; and the hand levers for wheeling are now made telescopic, so as to slide out of the way when the ladders are in use. Messrs. Heathman and Co., of Endell-street, have now opened a special department for lending any of their manufactures on hire to wiring contractors, who can avoid the cost of erecting expensive scaffolding by borrowing Heathman's patent tower ladders, which are made to telescope up to 60ft.

Nottingham.—On April 8 the following resolution was passed: "Resolved that the borough accountant be paid an additional salary of £100 per annum as accountant and collector to the electric lighting department" With the view of obviating the question of having an independent staff for the Electric Lighting Committee to keep accounts and to collect rents, the Finance Committee had made an arrangement with Mr. Bryan to take over the additional work at a remuneration of £100 per year Alderman Goldschmidt said at the last meeting that the Council would understand that by making that arrangement they had effected a great saving, because if the Electric Lighting Committee were to have an independent staff it would cost not one hundred but many hundreds of pounds The Finance Committee, in making that appointment, were of opinion that they were acting strictly within the powers assigned to them. If, however, the Council so desired, they were perfectly prepared at an early date to bring up a full report on the question.

Harrogate.—The Electric Light Sub Committee have reported to the Town Council that they had carefully gone through the detailed estimates laid before them by the electrical engineer, amounting, together with contingencies, to the sum of £23,500 for buildings and plant required for the installation of the electric light in Harrogate, as provided by the order of 1891, and they recommend that the detailed estimates submitted be approved and forwarded to the Local Government Board, and that the Board's sanction be asked to a loan for that amount, and also for a further sum of £1,500 for the purposes of street-lighting by electricity. The report was adopted by the Council, the Mayor (Mr. Fortune) explaining that they would have to await the sanction of the Local Government Board before proceedings could be taken and in the meantime they would get further information, and would be able to let the contracts in a fortnight or a month, as the case might be. It is proposed to have about 68 arc lamps in various parts of the town, and also to light the new baths electrically.

Kingswood (Bristol).—The following letter has been received from the tramways company by the Urban District Council: "I am instructed by my directors to thank you for your letter of the 19th ult., and they have given the matter their careful consideration, and regret they cannot comply with the whole of the conditions named by your Council. The plan which you have specifies the exact widths, and I think upon careful examination these will be found satisfactory. With regard to the wood paving and the question of applying for further parliamentary powers, these are matters upon which the directors are unable to give any undertakings, but they will be pleased to carry out the widening of the roadway for the whole length of the company's property, as shown in the plan, and to bear the whole expense of the adjacent footway; and with regard to the advantages which will then be secured by your district, I am instructed by the directors to express a hope that the plan enclosed with my application of the 17th inst. will receive your Council's approval at their to-morrow's meeting, so that the work may proceed forthwith —S. WHITE, secretary." This communication, which referred to the extension of the company's line to their yard at Warmley-hill, received the Council's approval.

Bolton (Lancs.).—Mr. Deakin moved, at the Guardians' meeting, that it be an instruction to the Decoration Committee to have the electric light installed in all the rooms of the union offices

Digitized by Google

except the Board-room and lavatories. He enumerated some of the advantages of having an electric installation, observing that the main objection which those who had spoken against it had was one of economy, but on this point he yielded to no one on the Board in his desire to exercise economy. He proceeded to show that an installation of electricity in that building would be more economical than gas, comparing the difference in cost between 100 electric lights and 100 ordinary gaslights, taking it on a basis of 500 hours burned per annum. The cost of gaslight, he said, was £46. 5s. and electric light £29. 9s , giving a saving in favour of electricity of £16. 16s. On the score of health he contended that electric light was preferable to gas, and in a decorated room the fumes from the gas had an effect on the decorations. Mr. John Taylor seconded, and Mrs. Ashworth supported, remarking that it was desirable from a health point of view that the electric light should be put in After some discussion Mr. Cunliffe moved that the electric light be introduced, and that tenders for the same be obtained. This was adopted by 29 votes to 15.

Edinburgh —On Tuesday the Cleaning and Lighting Committee of the Corporation recommended that the Grassmarket and West Bow should be lighted with electric light at a cost of £140. The Treasurer said he agreed that no more suitable place could be had for the electric light than the West Bow and Grassmarket; but since they framed the estimates they had passed electric light for George street at an expenditure of £880 per annum, and for the Mound at £160 per annum, or £1 040. He thought it would be better if the Cleaning and Lighting Committee could see their way to postpone this till next year Bailie Steel said his committee were very desirous that they should not go any further in this matter, but they felt that this claim of the Grassmarket was a very strong one, as the light in that district was insufficient. However, before they went further he thought they should have a general scheme for future extensions. Mr. Mackenzie (convener of the Electric Light Sub-Committee) agreed that they should pass the Grassmarket extension. The Cleaning and Lighting Committee also recommended the erection of an electric lamp at the corner of Picardy-place and another at the corner of London-road. This proposal, however, was sent back to the committee for reconsideration.

Copper.—According to a despatch from Houghton. Michigan, this year's output of copper by the Calumet and Hecla Company will be nearly 20,000,000lb. more than last year, an increase of one-third. Messrs. James Lewis and Son's monthly report on copper contains the following: A fairly large business has been done in good merchantable copper during the past month, the turnover being 20,000 tons as against 25,000 tons in August The chief feature of the market during the last month has been the large business done in "the call" of copper, 20s. being paid for the call of 3 000 to 4,000 tons at three months' date, and 8s. 9d. for the call of 300 tons at one month's date. Sellers of argentiferous pig copper and other furnace material have moderated their views somewhat, and a large quantity of matte and argentiferous bars has been sold in America to smelters in this country. Electrolytic copper is in fair demand for the Continent, and most manufacturers are fully sold for some time ahead. American shipments to Europe for September are 4 075 tons, making the total to date this year 48,918 tons, against 60,495 tons in the same period last year. Imports are 5,746 tons less, and deliveries 1,164 tons greater to date than during the same period last year. The total arrivals in England and France for the month have been 5,535 tons, and the deliveries 7,674 tons fine Stocks have decreased 2,139 tons. The arrivals in England from Chile during the month have been 1,376 and the deliveries 1,758 tons fine, and from other countries 2,397 and 3,477 tons fine respectively The arrivals in England from the United States have been 369 tons bars, 36 tons ingots. and 461 tons matte, equal to about 654 tons fine copper, and in France 150 tons fine. The Chile charters for the month are advised as 1,500 tons, and exchange 17⅞.

Weybridge.—In the course of a discussion on a gas contract, at the Urban Council meeting, a member said he saw in the report of the last meeting of the Council that Mr. Jarvis made a statement that it was found impossible to raise the £5,300 necessary for the purchase of the electric light works; but he quoted an article to prove that these were the days of cheap money. and that there need be no difficulty in procuring what was wanted at a fair interest. He thought the private consumers of the electric light had been badly treated, and it was discourteous of the Council not to have expressed some sympathy with them in their application. The speaker sincerely sympathised with those gentlemen who had wired their houses. What, he asked, was the proper course for them to have adopted? They ought first to have accepted the offer of the electric light company to continue the light for three months. They would then have had an opportunity of negotiating with the electric supply and the gas companies, and, by playing off one against the other, they would have got more advantageous terms. The electric supply company had offered to light them at £3. 7s. 6d. per lamp, and give them the option of continuing the light or of purchase. But they had never tried that. Then, again, the electric supply company had been asked for a guarantee, but what guarantee had they with the gas company? He felt that they had not been fairly treated. If they wanted a gas contract, by all means let them have one; but it should be done in a straightforward manner.—A communication has been received from the Board of Trade, stating that the Weybridge Electric Supply Company proposed to revoke the order allowing them to light the village, and asking if the Council had any suggestions to make on the subject. Upon the suggestion of Mr. Ward, it was agreed to write to the Board of Trade asking on what terms the order could be transferred to the Council.

Islington, N.—A correspondent writes: "The Electric Lighting Committee of the Islington Vestry have found it necessary to apply to the Vestry for £25,000, in addition to the £60 000 already sanctioned for electric works in the parish. The increase seems to be a result of under-estimates, together with the acquisition of more property in Eden-grove for the electric station than the original scheme included. The committee report that machinery working to the extent of 1,000 h.p., and capable of serving 11,000 incandescent lights of 8 c p. each, or their equivalent, and 100 arc lamps for street lighting, is now being erected at the station. The present station will, it is said, with very slight alterations, afford sufficient accommodation for further machinery, equal to between 3,000 h.p. and 4,000 h.p., sufficient for a very considerable extension of both the public and private lighting. The necessary works and appliances for lighting the leading thoroughfares of the parish extending from the Angel Hotel, along Upper-street, and the Holloway and Seven Sisters roads, to Finsbury Park, are rapidly approaching completion, and it is hoped that this portion of the parish will soon be lighted. Already the committee have entered into provisional contracts for the supply of private consumers, and the ratepayers of Islington are emboldened to hope that Islington, like St. Pancras, by retaining the supply of electricity in the hands of its local authorities, may ultimately reap a profit from the undertaking that will serve to reduce the local rates. The profit of a year's working in the neighbouring parish of St. Pancras was equivalent to a dividend of 6 per cent. It is an advantage to the Islington scheme that the London County Council have recently reduced the rate of interest on loans for electric purposes, repayable in 42 years, from 3 to 2¾ per cent." The London County Council have agreed to lend the Islington Vestry £5,150 to purchase property for the extension of their electric lighting works.

London (St. James's).—The St. James's Vestry have considered a report of the Works Committee cn the desirability of lighting the main thoroughfares with electric light, the best system of electric lighting for such thoroughfares, the estimated cost as compared with gas, and generally upon the whole question. The committee have, it appears, had before them schemes submitted by the St James's and Pall Mall Electric Lighting Company and the London Electric Supply Corporation for the lighting of the parish, together with observations by the vestry clerk on the schemes. The general manager of the St. James's and Pall Mall Company had, in answer to enquiries by the vestry clerk, sent a letter in which he pointed out that in four cases they proposed the removal of street refuges. Piccadilly presented some difficulties, and, together with the circus, would require special treatment. A total of 69 lamps was shown, and the arrangement for connecting these lamps was drawn in diagram on the Regent-street circuit. In the event of this company undertaking the laying of mains for the purpose, it is estimated that a sum of £5,000 would be required, and, subject to a satisfactory arrangement as regards the period of the contract to enable the company to make provision for this capital outlay, they have expressed themselves as willing to supply energy and to maintain in full running order each of the lamps requiring a current of 10 amperes for £30 per annum, the Vestry supplying and erecting the lamp posts complete with lamps, and the company supplying all mains, connections, switches, and other gear as required. The Vestry have, however, decided before proceeding further with the question to instruct the surveyor to fit several lamps in Regent-street with burners of different size and incandescent burners for the purpose of experimenting as to the possibility of improving the lighting of the main thoroughfares by means of gas. It was also decided to place an arc electric light over one of the refuges in Regent-street by way of experiment.

Coseley (Staffs.).—Mr. C. W. Shackleton, engineer and surveyor to the Coseley District Council, has presented a report on the lighting of the district. Estimates are given for lighting by oil, by gas, by incandescent gas, and by electricity, together with statistics collected from 55 towns as to the number of hours of lighting and the cost and consumption of gas, cost per lamp per annum, etc. With regard to an electric installation, Mr. Shackleton states that it is possible to light up straggling districts like Coseley with an electric light installation on the incandescent system; but he is convinced that without private lighting an electric installation for street-lighting would be too expensive for a place like Coseley, and therefore out of the question. The engineers he has consulted are agreed that the only system by which an extended, scattered, and thinly-populated district like Coseley can be effectually lighted at a moderate cost is that known as the high-tension alternating-current series system. For this scheme the district would be divided into eight or nine circuits, and supplied with current from the central generating station, and the best place this could be erected is on the Council's land at Roseville. The wires would be insulated and carried on poles overhead, and not underground, the former being the cheapest arrangement, but the provisional approval of the Board of Trade should be obtained for the permanency of the arrangement. In considering the electric question the Council must ask themselves the question whether they would undertake the electric lighting of their own district, or allow it to drift into the hands of a private company. To efficiently light up the whole district from 350 to 400 16-c.p. lamps would be required, with, say, from 20 to 50 75-c.p. junction lamps. To do this and provide for 2 000 8-c.p. lamps for private lighting, by way of a start, plant would be required which would cost between £12,000 and £14,000, the annual estimated cost being £1,555; but if 2,000 private lights were taken up, at least £1,000 per annum would be received as revenue. Mr. Robert Hammond

Digitized by Google

estimates that it should ultimately reach £2,000. For public lighting only the plant would cost £8,700, and the annual working expenses £1,226, equivalent to a rate of 6d. to 7d. in the pound. It has been decided to call a special meeting of the Council to consider the report.

South Staffordshire Tramways.—The Highway, Market, and Stables Committee of the Wednesbury Town Council have reported, with reference to the South Staffordshire Tramway Company, that the committee had asked the company to proceed with necessary repairs of the permanent way forthwith, and that the Board of Trade had granted an extension of time for the use of steam on the Wednesbury, Tipton, and West Bromwich lines until the end of the present year. Mr. Oldbury, in bringing up the report, expressed his satisfaction to find that the repairs were being made vigorously, and said he saw that someone at Tipton had said that Wednesbury and Darlaston were content with the existing state of things in respect to the tramways. That certainly was wrong. Wednesbury had always complained of the neglected condition of the permanent way, and had always deprecated and opposed any break of the communication between Wednesbury and Birmingham such as was proposed by the West Bromwich authorities. The Council ought to be quite prepared to go before the Board of Trade, if necessary, to fight for their rights—viz., the maintenance of the communication between Wednesbury and Birmingham. The Mayor said they had always expressed themselves favourable to an extension of the electric system; but Mr. Joynson considered they had never pledged themselves to any system Alderman Lloyd dissented from Mr. Oldbury's view that, if the cable system were laid as far as Carter's Green, Wednesbury would be cut off from Handsworth and Birmingham. Rather, as the cable gave a quicker movement than any other system, they would be able to get from Wednesbury to Birmingham in less time than under the present system. He hoped the Council would do their utmost to abolish the steam system to Handsworth, and, with the concurrence of the West Bromwich authorities, to introduce the electric system. The Mayor said that Wednesbury and Tipton would be quite satisfied with that system, but he did not think they ought to disagree with West Bromwich and Handsworth if those places wanted the cable. Mr. Griffiths argued that if the cable system were brought as far as Carter's Green it ought to be continued into Wednesbury, but Alderman Kilvert and others considered that could not be expected because of the cost, which the company could not bear, and engineering difficulties.

Oswestry.—With regard to the electric lighting of the Cross-market, it was stated at the Town Council meeting that the Oswestry Electric Lighting Company were prepared to supply six 500-c.p. lamps at £40 per annum, the cost of the gas-lighting at present being £42 3s. 6d. The tender of Mr. Reakes, of Shrewsbury, for the installation of the lighting at £52 was accepted. A correspondent writes: "Many of the principal residents and tradespeople of Oswestry are at present greatly interested in the lighting of the town by electricity supplied by the Oswestry Electric Light Company. A company has been formed with £10,000 capital, issued in 10,000 £1 shares. The registered office is at Albion-chambers, Oswald-road, the secretary being Mr. W. W. Coulson. The chairman of the directors is Mr. A. Wynne-Corrie, Park Hall, Oswestry, the other directors being Mr. G. Perks, mayor of Oswestry, Mr. Robert Lloyd, Rhianva, and Mr. Josiah Jones, Salop-road; while Mr. E. Bremner Smith is managing director and engineer, Mr. H. J. Wallace Pugh, solicitor to the company, and Mr. C. E. Williams, auditor. The bankers of the company are Lloyd's Bank. The company have, under the superintendence of Mr. E Bremner Smith, who prepared the plans and specifications and carried out the work of erection, built a commodious engine-house in the Coney Green. The building is equipped with two 60-h.p. steam-engines with boilers of the multitubular type, which drive two 30-kilowatt shunt dynamos. The dynamos are driven by eight ropes from each engine. Between the steam-engines is a water-heater for utilising waste steam. The engines are by Messrs. Marshall and Sons, of Gainsborough, whose local agents are Messrs. John Minshall and Co., of Oswestry. It was not originally intended to run both engines simultaneously, but from the large demands for the light it is expected that both engines will have to be run shortly. The system of distribution is the low-tension at a voltage of 105. The current is transformed up from 100 to 145 volts for charging the storage batteries. Above the motor is a switchboard, supplied by Messrs. Parker and Co., of Wolverhampton, with a double-pole switch of an improved type, double-pole fuses, ammeters, and Kelvin voltmeters. The battery-room contains D P. batteries consisting of 55 cells. The cables, by Messrs. Callenders, of Erith, are laid in earthenware conduits under the footpaths. The engines began running permanently on Monday week. Considerable interest has been aroused by the installation at Mr. Robert Lloyd's establishment in Cross-street, which includes a 1,000-c.p. lamp at the centre of his buildings, which illuminates the neighbourhood."

Electric Mining Plant.—Last Saturday a large company of mining engineers and others visited the works of Messrs. Ernest Scott and Mountain, Limited, electrical and general engineers, at Close, Newcastle-on-Tyne, the chief object being an inspection of some very fine and powerful electric transmission plant constructed by the firm for the St. John d'El Rey Mining Company, and to be used in the company's Morro Velho mines in Brazil. The plant consists of two 50-unit 750 volts special Tyne dynamos, with sliding bed-plates; one main switchboard with measuring instrument, and main and underground cables; two electric winding cases, each fitted with Tyne electric motors of 30 effective horse-power; one air-compressor, driven by a 30-h.p. Tyne electric motor; and two fans combined with Tyne electric motors, switches, resistances, etc. The dynamos are of Scott and Mountain's improved mining type, and are each capable of easily giving an output of 70 amperes, 750 volts, at 650 revolutions per minute. The main switchboard is designed for using two lines of cables, and it is fitted with two voltmeters, each to read to 800 volts; two ampere-meters, to read to 100 amperes; and two double-pole quick-break main switches and double-pole fuses. Where the current is taken underground it is conveyed by 2 700 yards of $^{19}/_{16}$ cable, very heavily insulated with vulcanised indiarubber and armoured with galvanised-iron wires. There are two winding gears, each driven by Tyne electric motors of 30 effective horse-power, with a speed of 500 revolutions per minute. Each gear is designed to lift vertically a load of 3 800lb. at a speed of 120ft. per minute. Three motors are provided, two being utilised for driving the winding gears, and one for the air-compressor. Each motor is capable of easily giving 30 effective horse-power at 500 revolutions per minute, and is of the firm's improved type. Special starting switches are provided, so that the motors can be stopped, started, or reversed, or run at any speed. These are of special design to avoid sparking, and at the same time prevent the current being too suddenly switched off, which might damage the insulation of the machines The air-compressor is provided for supplying air for rock boring and other operations at the mines. It is fitted with a cylinder, 12in. in diameter by 16in. stroke, and runs about 600 revolutions per minute. Two steel receivers are provided for storing the compressed air. Two of Scott and Mountain's electric fans are supplied for ventilating the mine, etc. Each fan will deliver about 3 000ft. of air per minute at 2in. W.G., and is fitted with a single inlet impeller of 24in. diameter and performing 1,000 revolutions per minute. The plant was much admired by the large number of experts present. In other parts of the works—which, by the way, are at present undergoing important extensions—there was much to interest the visitors. Messrs. Ernest Scott and Mountain are at present extremely busy in all departments of their business. Besides colliery pumping machinery, a very large number of electric light installations are in hand.

Swansea.—Alderman Richard Martin has moved the adoption of the Corporation Electric Lighting Committee's scheme. He said they were told Swansea could not afford such a scheme; that they were spending a lot of money on the market, the Cray water scheme, sewerage, etc. These people had forgotten to include the widening of the streets. That ought to have been put in. But he wished them to understand there was a significant difference between those schemes and the one now before them. The electric lighting scheme would pay for itself, and would in a short time become a lucrative monopoly. They asked the ratepayers to secure the control of a necessary and not an expensive monopoly, but one which would be very lucrative, and confer upon them privileges they did not now enjoy. A few years ago he (Mr. Martin) wanted the Corporation to take over the gasworks company. He was sorry he failed. He thought the gas company were very badly advised. while the Corporation were just a trifle too selfish—they were fearful of the electric light. His claim was that if the Corporation had taken over the gasworks they would have secured a very valuable asset. He appealed to them not to allow the electric lighting of the town to go into private hands, and if they would do what he advised them to do they would yet take over the gasworks. Even the Cray scheme would eventually prove lucrative, providing it was properly worked. He did not think Swansea people wished to be behind the age. They had been badly treated by the gas company, and if properly treated by the Corporation he was sure they would assist them in making the electric scheme a great financial success. Let them adopt the policy of the Brighton Corporation, where a man who used the full capacity of light for four hours was charged only 3d. per unit. He did not know whether they could get gas equal to 3d. per unit. In conclusion, he advised them not to let the chance go by of acquiring for themselves the power of supplying what was the necessity of the day—electric lighting. Mr. R. S. Lindley, who seconded the motion, said a great deal of doubt was expressed as to the possibility of revenue from electric lighting. He thought that doubt ought to be removed by the mere fact that, firstly there were several private contractors ready the moment they allowed their time to slip to come in and take up the lighting of the town. They would not do it if they did not see the prospect of a revenue in it. Moreover, they would require a higher profit than the Corporation would require a revenue, because they would have to pay interest to shareholders. If the Corporation accomplished the work themselves, the revenue they would get would go directly to repaying the expenses. He quoted the case of Manchester, which supplied its own current. There they had gone in for a total expenditure of £175 000 for their electric light, and in the second year of its working they had a revenue of 12 per cent., after writing off for depreciation, sinking fund, etc., a sum of £7,500. He thought that a great encouragement for Swansea to go ahead. After a protracted discussion, the electric lighting scheme was adopted by a majority of one.

Eccles.—The last proceedings of the Town Hall, Tramways, and Electric Lighting Committee of the Town Council stated that at a meeting of the committee held on the 1st inst. tenders were submitted for the carrying out of the various works comprised in the scheme prepared by Mr. S. V. Clirehugh for electric lighting in the borough, providing for the lighting of the whole of the street lamps, which were at present lighted by gas, and for such an amount of private lighting as the committee considered at present advisable, and fulfilling the obligations which the Council

Digitized by Google

were under pursuant to their electric lighting provisional order. The tenders were of amounts which showed that the whole of the works, including buildings, etc., and adding 10 per cent. for legal charges and contingencies, could be carried out for the sum of £18,761, or £210 under the engineer's estimate, which was £18 971. The committee resolved that the Council should be recommended to accept the tender of the Manchester Edison-Swan Company, Limited, at the sum of £13 792, subject to the Local Government Board granting to the Council borrowing powers adequate for the carrying out of the whole scheme of electric lighting A further resolution of the committee recommended that application be made to the Local Government Board for power to borrow £20,000 for the purposes of the electric lighting scheme. Upon the motion by Alderman Kendall for the adoption of the report, Mr. F. Smith moved as an amendment that the acceptance of the tender be deferred. He said there would certainly be five members of the Council who would not return after November, as they did not intend to seek re election, and the matter of the electric lighting of the borough was one of such magnitude that it should be deferred until the new Council—who would have the carrying out of the work and who would be responsible for it—were elected. Alderman Kendall said he was rather astonished at the force of the opposition. There was no desire for unseemly haste on the part of the committee. With regard to the outside opposition that had been referred to, people had been told that the introduction of the electric light would mean an addition of 3d. in the pound on the rates. They were at first told that it would be 1s., but it had come down to 3d. It was to be remembered that the street-lighting with gas cost 4d. in the pound, and that, of course, would not have to be paid if they used electricity. The engineer would light the streets with electricity for the same price as gas. He thought the introduction of electric lighting would be a perfectly safe matter financially. There was, indeed, a company who were prepared, if the Corporation carried out the work, to run the light, paying depreciation, sinking fund, interest or whatever they liked, if they might be allowed to have the balance. It was to be remembered also, that they were at the present time getting their gas from a neighbouring borough. The Local Government Board would not grant them a further extension of their order. If the recommendations of the committee were rejected, the responsibility would not lie with the committee. The amendment was, however, ultimately carried.

Runcorn.—In accordance with notice given, Dr. Gastaldi moved at the Urban District Council meeting that it is in the interest of the ratepayers of Runcorn that electric lighting be introduced in the town and that a committee be appointed to carefully consider the subject. He said Staffordshire in that direction was well abreast of the times, and the Corporation electric supply of Stafford was already inaugurated, and that of Walsall coincided with it. A more remarkable portent of the times was that the small county town of Cheadle and the still more remote district of Alsager, on the northern boundary of the county, had a scheme under consideration, whilst the Rugeley Urban Council had announced their intention of taking into consideration the lighting of their streets with electricity. If places second in importance to Runcorn considered that electric lighting would be a boon to them, why should not Runcorn consider the question in the interest of the ratepayers? His reasons for its introduction were (1) that the town would be better lighted than at present; (2) that the town lent itself in a remarkable manner to provide electricity; (3) that in the ultimate end it would be the cheapest light; (4) that it would be a source of great revenue to the ratepayers. No one could gainsay his assertion that the town would be better lighted. During July and August, no gaslight was used no matter how dark the night might be, and the inconvenience was greatly felt by the ratepayers, who paid dearly for light they did not receive That anomaly would be absolutely removed if they adopted the electric light, because it would be the property of the town. With regard to his second point, as to Runcorn lending itself to provide electricity, he might say that at the waterworks they had got three boilers capable of producing any quantity of steam for the purpose of generating the motive power, capable of revolving the most powerful dynamos. They had there ample space for placing the necessary machinery to distribute electricity. Further, the Council was at the present time studying how to get rid of the nightsoil on account of the great cost involved in disposing of it, and the question of providing a destructor had occurred often to them. The difficulty would have to be met, and his idea was that if a destructor was erected it would provide nearly sufficient fuel to provide the motor power for the dynamo, and thus generate the light of the town out of the town's refuse. Then they had water near them—the Vyrnwy (Liverpool) supply—from which they could purchase additional power, which with the destructor would produce a powerful motor for the supply of electricity. In support of the third argument he would urge the dearness of gas. They paid now for the lighting of the streets nearly £900 a year. If they capitalised that amount it would give them, at 3 per cent., £30,000 of borrowed capital, and with that amount they could easily put up all the needed machinery and plant, and supposing that in 30 years they repaid the borrowed capital by a sinking fund, in 30 years the electric light would be a source of great revenue to the town as they would cease to pay rates for the lighting of the public streets, and have the revenue from private consumers to go to the lessening of the rates. He asked them to consider the question, and for that purpose to appoint a committee to go into the matter carefully and carry on investigations on all points. Mr. R. A. Posnett seconded the resolution. After a long discussion, in which several of the members, suggested on the committee, declined to be put on, the committee as suggested by Dr. Gastaldi was ultimately appointed.

Brighton.—A correspondent writes: "In the long debate that took place in the Brighton Town Council with regard to the request made by the Brighton and Rottingdean Seashore Electric Tramroad Company for permission to erect 13 steel poles on the foreshore between Paston-place and the eastern boundary of the borough, there was a general misunderstanding on one point that is well worth clearing up. Practically the debate turned on the advisability of conveying an electric current by underground or overhead wires, the comparative cost of the two methods, and their different effects on the amenities of the Front. If it were only a matter of conveying an electric current from one place to another no one doubts that it should, if possible, be done by underground wires, and, as a matter of fact, the difference in the cost would not be material. Considering the cost of the steel poles the underground method might possibly be even cheaper. But the electric cars are to be worked on the trolley system. The Board of Trade have given their approval to this, and without the slightest hesitation granted the company power to put up these poles in so much of the foreshore as is within their jurisdiction. If, therefore, the Corporation refuse to allow this overhead wire within the borough, the company will have to change the system when they come to the borough boundary. This means the carriage all the way of at least five tons of accumulators, simply in order to get over the half mile in Brighton, and as a matter of fact, no tramway worked with accumulators has yet been a commercial success. As to any danger from the wire, the Board of Trade have satisfied themselves on that point. Twenty-one feet above the highest tides is the height for the wire sanctioned by the Board of Trade, but the company have left it to the borough surveyor to determine the height he thinks necessary to let the Brighton boats go under. The poles would run along the side of the tramroad simply at such a distance therefrom as would prevent any foolish passenger from reaching them with a stick or umbrella—that is, roughly, they would be from 100 to 400 yards at sea south of high water mark. Practically the poles would be very similar to the standards at present being erected on the Marine-parade, only without the ornamentation; and, considering the distance of all the houses from the edge of the cliff, it is urged that they could hardly be an obstruction or eyesore in any way, as it is impossible to see the line at all from the windows of the reception rooms of the houses in this part of the town. It is hoped that on the matter again coming before the Council no further obstacle will be placed in the way of the completion of a most interesting undertaking—one calculated to attract still more attention to the eastern part of Brighton." At a meeting of the Lighting Committee the town clerk reported that he had arranged with the Brighton and Hove General Gas Company to continue the lighting of the streets proposed to be lighted by electricity in the borough until such time as the electric lamps are ready for use. Having regard to the introduction of electricity cables within the Town Hall to provide the motive power for the passenger-lift, the General Purposes Committee recommend that the electric light should be used in the town clerk's temporary offices now being erected in the assembly-room at the hall.

Oxford.—The Streets, Roads, and Lighting Committee of the City Council reported that they had received the following proposal from Mr. McLean, managing engineer of the Oxford Electric Company, Limited: "I have pleasure in submitting further amended schemes for the electric lighting of the principal streets of the city. Plan C shows the 32 lamps divided up as follows: eight all-night arc lamps placed at the following spots—opposite Beaumont-street and St. Giles-street; the junction of Broad-street and Cornmarket-street, Carfax; corner of St. Ebbe's-street and Queen-street; corner of Turl-street and High-street; opposite Catherine-street in High-street; opposite Queen's-lane in High-street; corner of Longwall in High-street. All these lamps are in existence with the exception of the last two named. The remaining 24 lamps, the positions of which are indicated on the plan, to be lighted three-quarters of an hour after sunset as at present, and extinguished at 12 midnight. On each of these 24 lamp-posts, a double bracket would be placed about half-way up, each bracket carrying a 32-c.p. incandescent lamp, which would be lighted at midnight and turned off at daylight. This arrangement would cost you £688, made up as follows: £26 each for all-night lamp, and £20 for each combination lamp. Should you, however, consider two lamps of 16 c.p. each would be sufficient for the 24 combination lamps, the cost to you would be £652. This is on the basis of 24 lamps at £18 10s. each. Instead of a two-light incandescent bracket, a single one could be substituted, if you preferred it, with equal candle-powers as above. The points in favour of either of these schemes over those previously submitted, and over the present system, are as follows: the half-night arc lamps are burned till midnight, instead of being extinguished at 11·45 p.m., as at present, and on each post incandescent lamps are supplied all night, affording ample light for the traffic after midnight, the eight arc lamps being reserved only at the principal corners." The committee recommended that the proposal therein contained be accepted, using the lamps of 16 c.p. for the 24 combination lamps, making the total annual cost £652; and that a contract be entered into for this purpose for a term of six years, determinable at the end of the first three, then at the option of the Corporation. Mr Kingerlee said they had given the gas company every opportunity of lighting the streets of the city, and he thought the experiment that had been tried in Beaumont-street was a very successful one, and it had been carried out at a very small cost. The electric

Digitized by Google

company had also offered them certain advantages in the matter of lighting, and, with the 16 lamps that they had set up, the city got 30 times the amount of light they used to have from the gas lamps. Now the company offered them further facilities, and they proposed to increase the number of lights to 32, and to increase the power of the present lights from 1,200 c.p. to 2,000 c p. each. The old gas lamps had not been removed, and the cost of keeping them in repair amounted to £27. 13s. 5d. per year, and he proposed that the report of the committee be confirmed. The committee had a balance to the good of over £60 on the estimate for the half-year's lighting. Alderman Buckell said the city was interested in getting the best light it could, whether it be gas or electric light. The electric company had made proposals for extending their system and of increasing the present power of the light at a comparatively small cost, but at the expense to themselves of some thousands of pounds. He urged that both the gas company and the electric company should be allowed to do the best they possibly could. The citizens would have more than double the amount of light at less than half the cost of the present system. The report was adopted.

Marylebone.—Mr. T. H. Brooke Hitching, a member of the Marylebone Vestry, has printed a pamphlet entitled "Cheap Electric Light for Marylebone," from which we extract the following: No stranger traversing the streets of Marylebone on a winter evening, and observing the dull flicker of the public gas lamps, would believe that Marylebone is one of the wealthiest and most aristocratic parishes in London. Marylebone, with its 63 miles of public streets, its £1,500,000 ratable value, and its 140,000 inhabitants—largely of the upper and middle classes—is publicly lighted in a manner inferior to many small provinclal towns. Several of its principal shopkeepers—and Marylebone contains some of the largest shops or stores in the world—find it necessary to supplement the public gas lamps with outdoor electric lights, supplying the current at their own cost. The semi-darkness of the present lighting system is a reflection on the greatest capital of the world, and is calling forth caustic comments in the daily newspapers, which ask why the rich West-end parishes are so miserably and inadequately lighted; and do not hesitate to charge the West-end vestries with a lack of proper public spirit. In some instances the Press even advocate that the public lighting of the Metropolis should be under the direction and control of that already overworked body—the London County Council. The problem of efficient public lighting on the most economical basis is, however, now engaging the attention of a large number of our municipal corporations, vestries, and urban district councils. Since the proved success and high efficiency of electricity as an illuminant have been so largely demonstrated, many local authorities have decided to establish their own electric light stations, not only for the purpose of street-lighting, but also for the purpose of supplying the public with the light at reasonable but remunerative prices. London is considerably behind the provinces in respect of municipal undertakings, probably because Londoners have had no experience of the great advantages—pecuniary and otherwise—of municipal ownership of gas and water undertakings. Within the county of London, St. Pancras and Hampstead are the only parishes possessing municipal electric light stations. Shoreditch and Islington are, however, rapidly following suit, and other vestries have the question under consideration; but so far nearly all the electric light supply in the Metropolis is in the hands of limited liability companies. It is urged by some persons that electric light costs more than gaslight per candle-power, but this assertion is easily refuted when one takes into consideration all the advantages of electricity—the ease with which the consumption is controlled, together with its cleanliness and safety; and the refutation is confirmed by the very general adoption of the light by the largest commercial houses. With present appliances it may be generally accepted that electric light at 6d. per Board of Trade unit is equal to gas at 3s. per thousand feet The gas monopolies are already feeling the competition, and more economical gas-burners are being placed on the market. The increased cost of these, however, and their constant need of renewal make their acquisition of doubtful value from a pecuniary point of view. For the purposes of private lighting the Metropolitan Electric Supply Company have at present a monopoly in the parish of Marylebone, and this company appears to do its work in a manner fairly satisfactory to its customers. Notwithstanding its immense capitalisation—£500,000—and its heavy expenses as a public company, with its directors' fees, salaries, insurance, office and legal expenses, the Metropolitan Electric Supply Company is in a very prosperous position. It has a revenue of 8s. 5d. per lamp on no fewer than 209,000 lamps, making a gross profit in 1894 of £30,078 or nearly 5 per cent. A large portion of this profit is derived from Marylebone ratepayers. The charge per Board of Trade unit is 7½d. The revenue has regularly increased, and at present (September 21, 1895) the £10 shares of the Metropolitan Supply Company are quoted at £12. 5s. to £12 15s., whilst the £10 founders' shares are quoted at £270 to £300 each! The metropolitan parish of St. Pancras, which does its own public lighting, supplies electricity to the public at about 5½d. per Board of Trade unit, and owing to the excellent municipal management the electric lighting makes a profit of no less than 7 per cent. per annum. The generation of electricity should only be in the hands of the local authorities, which can manufacture and supply more cheaply by far than any limited liability company; the local authority has a staff at hand for collecting the accounts, and it would then more effectively control the taking up of public streets and roadways than is the case with the supply in private hands. Shoreditch is not a wealthy parish of the Metropolis, but it has many "practical" gentlemen on its Vestry Board. Shoreditch is now lighted with gas, but the Vestry has decided to establish an electric light station. A suitable site has been acquired, on which is to be erected a station with the latest improvements in electrical engineering. This will cost £4,000. A range of four tubular boilers will generate sufficient steam to work three electric generators of a capacity of 150 kilowatts each, one of 50 kilowatts, and two of 15 kilowatts, and three arc light generators of 20 kilowatts. Cost, £24,000. Two sub-stations and complete apparatus will add £7,400 more. A dust destructor, or in this case a dust utiliser, with 14 furnaces and boiler-house complete, will cost the parish £8,000. The mains, conductors, conduits, arc lamps, etc., about £20,000 more. In all some £63,000. The advising engineers to Shoreditch Vestry (Messrs. Kincaid, Waller, and Manville) estimate that the plant specified above will be capable of supplying current for 15,000 lamps. These, at a charge to the public of 6d. per unit, they estimate will yield £7,500 per annum. The engineers also estimate that the utilisation of the dust for fuel will generate all the steam necessary for producing the electricity, and will, in addition, supply the baths and wash-houses with hot water and steam—an annual saving to that department of no less than £500 The Vestry now pays some 3s. per ton for the disposal of its 20,000 tons of dust—each year £3,000. The engineers estimate the cost of destroying this refuse at £1,000 for wages—with £250 for repairs £1 250, a further saving to the Shoreditch ratepayers of £1,750 per annum. Prof. Forbes several years ago advised Paddington Vestry to utilise its dust for the purpose of generating steam for electricity, so the idea has no novelty. It rests, however, in the county of London on the East-end parish of Shoreditch to prove its efficiency and economy. Dr. Robinson, clerk to the Shoreditch Vestry, estimates that in 42 years the parish will not only pay off its debt on the electric light undertaking, but will, in addition, possess an asset worth, with goodwill, not less than £100,000 even if no extension takes place. He adds: "If, however, the more favourable view of the case be taken, and the extensions which the engineers anticipate are realised, involving a proportionately greater profit at comparatively little increased expense, the proposed undertaking assumes very large proportions, and offers such magnificent profits that it would, in my opinion, soon compare favourably with the most successful gas or water monopolies." The Liverpool Corporation is so impressed with the desirability of possessing the electric light supply of the city that it has recently purchased the plant and generating station of the limited company which has hitherto sold the light to the citizens. In Marylebone the cost of carting and disposing of the dust for one year, 1894 5, was £7,300, including collection. This work is done by contract. The cost of lighting the parish, 3,640 lamps, was £10,215, and maintenance £756, together £10,971. The cost of fuel to the Baths Commissioners for the last complete year was £597. These figures involve large payments out of the rates, payments which would probably be much reduced by a more progressively practical management. An opportunity now presents itself for Marylebone to be the pioneer among West-end corporate bodies of the county of London, in the establishment and maintenance of a municipal electric lighting station—a station which could not only light the streets of Marylebone in a manner befitting the wealth and importance of the parish, but would supply to the Marylebone ratepayers the best of all illuminants at a cost lower than that of gas. Better lighted streets mean to the residents greater safety; to the tradespeople better business; and to the parish greater prosperity. In the production of this light the dust and refuse of the parish might be destroyed, without emitting disagreeable fumes, and at a saving probably of £5,000 per annum. And ultimately, when electricity becomes the universal artificial illuminant, a large profit will accrue to the parish, which will have the effect of reducing the burdens of the ratepayers so far as the purely local rates are concerned. This course, if adopted, will break down the gas monopoly—which takes from Marylebone very many thousands of pounds per annum—and will create the first profit-bearing municipal undertaking in Marylebone, and fit it to rank as a corporation with Birmingham, Manchester, and the other chief municipalities of the kingdom. On July 18, 1895, the Marylebone Vestry, on my motion, resolved, "That it be referred to a special committee to be appointed to consider and report as to the desirability of lighting the parish by means of electricity, and as to the desirability of the Vestry undertaking the work, and that the committee be empowered to make the fullest preliminary enquiries of those metropolitan vestries which have adopted this course" The members chosen are Mr. Curry, Mr. Emery, Mr. Hopkins, and the writer—Mr. T. H. Brooke Hitching.

PROVISIONAL PATENTS, 1895.

SEPTEMBER 23.

17734. **A new or improved electrical alarm and connections therefor.** Henry Landergan and Gerald Cuthbert Grahame, 63, Clapham-road, London.

17741. **A new or improved device for indicating the duration of telephonic conversations.** Romain Van Kerckhove, Norfolk House, Norfolk-street, London.

17745. **Improvements in or relating to electrolytic cells.** Henry Harris Lake, 45, Southampton-buildings, Chancery-lane, London. (Carl Hoepfner, Germany.)

Digitized by Google

SEPTEMBER 24.

17758. **An improved automatic electrical cut-out.** Martin Edward Crowne and Henri Charles Fowler, 11, Furnival-street, Holborn, London.

17773. **An improvement in telephone fittings.** Edward Morris Edelsten, 10, St. George's-crescent, Liverpool.

17782. **The adjustable electric dial contact.** George Wall, 10, Nairn-street, Poplar, London.

17788. **Improvements in electromotors.** Dugald Clerk, 18, Southampton-buildings, Chancery-lane, London. (Howard Lacy, Louis F. Johnson, and Walter J. Slacke, United States.) (Complete specification.)

17790. **Improvements in electromagnets and method of winding the same.** Dugald Clerk, 18, Southampton-buildings, Chancery-lane, London. (Howard Lacy, Louis F. Johnson, and Walter J. Slacke, United States.) (Complete specification.)

17791. **Improvements in dynamos.** Dugald Clerk, 18, Southampton-buildings, Chancery-lane, London. (Howard Lacy, Louis F. Johnson, and Walter J. Slacke, United States.) (Complete specification.)

17821. **Improvements in or connected with secondary batteries.** Frank King, 47, Lincoln's-inn-fields, London.

17830. **Improvements in and relating to mechanism for electrically indicating the extinction of lamps and for analogous purposes.** Henry Harris Lake, 45, Southampton-buildings. Chancery-lane, London. (Horace See, United States.) (Complete specification.)

17864. **Improvements in or relating to electric indicators or annunciators.** John William Hall, 323, High Holborn, London.

17871. **Improvements in compositions for protecting ships' bottoms against fouling, preserving wood, and shielding submarine electric cables from penetration by torpedo worms.** William Livingston Gunn, Lloyd's Bank-buildings, Bristol.

SEPTEMBER 25.

17918. **Improvements in the manufacture of incandescent electric or glow lamp.** Percy Head Baily, 62, Darnley-road, Hackney, London.

17919. **Improvements relating to telegraph and like poles.** Frank Everett Garner and Charles Robinson Bliss, 55, Chancery-lane, London.

17921. **Improvements in the manufacture and production of filaments for incandescent electric lamps.** Joseph Wilson Swan, 47, Lincoln's-inn-fields, London.

17924. **Electric smoke annihilator.** Richard William Hill, 97, Newgate street, London.

17925. **Production of carbonate of soda and chlorine gas by electricity.** Richard William Hill, 97, Newgate-street, London.

SEPTEMBER 26.

18018. **Improvements in incandescence electric and gas lamps and lanterns.** Vittorio Croizat, 28, Southampton buildings, Chancery-lane, London.

18033. **Improvements in or relating to developing displaced magnetic phases and producing rotary magnetic fields.** William Phillips Thompson, 6, Lord-street, Liverpool. (Charles Schenck Bradley, United States.) (Complete specification.)

18034. **Improvements in oxidising lead and lead compounds for the construction of electrical accumulators.** Henry Leitner, 31, High Holborn, London. (Complete specification.)

18036. **An improved process for the preparation of electrodes for primary, secondary, and dry batteries.** Henry Leitner and Emanuel Reicher, 31, High Holborn, London. (Complete specification.)

18038. **Improvements in and appertaining to electrodes.** Henry Leitner and Emanuel Reicher, 31, High Holborn, London. (Complete specification.)

SEPTEMBER 27.

18065. **Improvements in the method of and means for electrically illuminating block dials and signs.** John Haynes and Herbert Hampton Hall, 57, Barton-arcade, Manchester.

SEPTEMBER 28.

18152. **Improvements in telephones.** Rudolf Goldlust, 19, Southampton-buildings, Chancery-lane, London.

SEPTEMBER 30.

18200. **Improvements in connection with arc lamps more particularly adapted for electric searchlights.** Frank Michael Lewis, 2, East-parade, Leeds.

18226. **Improvements in secondary batteries.** Carl Fisker and Louis Bertram, 1, Broad-street-buildings, Liverpool-street, London.

18236. **Improvements in or connected with electric burglar and other alarms.** Thomas Alfred Clarke, 6, Lord-street, Liverpool.

OCTOBER 1.

18305. **Improvements in means of supporting and insulating electric conductors within culverts or like conduits.** Rookes Evelyn Bell Crompton, 55, Chancery-lane, London.

18369. **Improvements in electric locomotives.** Jean Emile Amen, 65, Chancery-lane, London.

NOTES.

Writer's Cramp Cured by Electricity.—The New York *Medical Journal* reports the cure of a case of writer's cramp in a telegraph operator by applications of static electricity.

The Physical Society.—At the meeting of this society on October 25 the following papers will be read: (1) "The Radial Cursor," by Mr. F. W. Lanchester; (2) "The Development of Arbitrary Functions," by Prof. Perry and Mr. Hunt.

Electric Hearses.—An electric tramway has been laid from the Cimitero Monumentale, Milan, to the new burying-ground at Musocco. A special black hearse-car serves for the transport of the corpse. The mourners follow in a passenger car.

Accumulator Patent Dispute.—The Berlin High Court has dismissed, with costs, the appeal of the Akkumulatorenfabrik A.-G., of Hagen, against the decision with reference to the form of accumulator manufactured in Berlin by A. Boese and Co.

Obituary.—Ingenieur und Geh. Kommerzienrath Eugen Langen, who died recently, was not, as has been stated in some papers, a member of the firm of Felten and Guilleaume. He was, however, one of the directors of the Elektrizitäts-Gesellschaft Schuckert, the Hörder Bergwerks-Verein, the Gasmotorenfabrik Deutz, etc.

Visiting the States.—The president of the Tramways Institute of Great Britain and Ireland, Mr. W. J. Carruthers Wain, C.E., is again visiting the United States and Canada on a mission of further enquiry into the question of electric traction, and to that end he will personally inspect all the newest and improved methods of traction in the United States.

Telephonic Communication between Belgium and Germany.—On Tuesday, Belgium and Germany were placed in direct telephonic communication with each other. Antwerp and Cologne are the extreme points between which conversation can be carried on, and the price for three minutes' use of the line varies from 1·25c. to 2f., according to the distance.

The First Electric Railway in Mexico is soon to be in operation in the State of Vera Cruz. It will run from the city to Orizaba, a distance of about 90 miles. The construction of the line is now in progress. It will pass through Coatepec, Jico, and other towns in the rich coffee district of the State. General Frisbee is the owner of the concession for the railway.

African Chiefs and Electricity. — It will be remembered that Nasrulla Khan was very much impressed by the generating apparatus of the Liverpool Overhead Railway. A similar experience has befallen the three African chiefs Khama, Sebele, and Bathamen during their visit to the northern city; indeed, they were so struck with the power and genius of the engineer, Mr. Cotterill, that they incontinently dubbed him, and afterwards persistently referred to him as, "the King of Lightning."

France and Submarine Cables.—The *Débats* again warns Parisians against the risk which France runs in time of war in permitting England to possess a monopoly of the submarine cables. France, it says, must at all costs be made independent of England in this respect. The present it considers a favourable opportunity for doing so. On all sides a final effort is being made to throw off the "English yoke." Japan and the United States, the journal adds, are extending their hold over the cable system, one of the French companies is showing renewed enterprise, whilst the Minister of Commerce declared at Calais the other day that he would soon give the cable company there some work to do.

The Electric Incubator, upon which Herr Otto Schulze, of Strasburg, has been at work for three years, is intended to overcome the ordinary difficulties of artificial hatching of chickens. The apparatus, it is said, is easily manipulated, and requires only an uninterrupted but small supply of electricity. Automatic attachments regulate both temperature and moisture, the former being kept within one-tenth of a degree of the normal temperature of incubation. In this apparatus 90 in every 100 eggs are expected to hatch. An electric mother, a box in which the freshly-hatched chicks can find heat and protection, while being at liberty to run about on the ground when they choose, has been devised as an accompaniment of the incubator.

Novel Use of the Searchlight—The searchlight has recently been put to a rather suggestive use at Stalybridge, at Messrs. Gartside's works, where there is a strike, in connection with which rioting has taken place. The light has been used "with the idea of preventing the striker from maliciously setting fire to the temporary sheds erected for the protection of the men at present employed.' It is now being used nightly, in conjunction with the police force established at the works, to search the surrounding country and to illuminate the various parts where pickets are placed. It is said that the arrangement enables the services of a number of policemen to be dispensed with. The light used is one of Messrs. Baxendale and Co.'s "Ship Canal" class.

Now Antilles Cables.—The Spanish journal *El Heraldo* says that the Colonial Minister has signed a contract with an English firm, the Cuba Submarine Company, for the laying of cables connecting Cienfuegos with Las Tunas, Júcaro, Santa Cruz, and Manzanillo, so that Habana may be in telegraphic communication with the whole of the southern coast of the island of Cuba. The concession is to be valid until August, 1910. The amount agreed upon for the work is 10,500 pesos annually, payable in Cuba in monthly instalments during the 14 years. The cables were required to be laid by January next, and it is expected that the company will have them down during December. The tariff for dispatches will be in accordance with the rates at present ruling, but there will be a reduction of 50 per cent. to Government officials.

Spanish Ship Wiring.—A Spanish man-of-war has has been run down at Havana with great loss of life. After the collision became inevitable, and in the excitement and rush, "a fireman stumbled against the electric wires supplying light and displaced them, and in an instant total darkness enveloped the ship. Under such circumstances the ship was doomed." We should think, remarks a New York contemporary, from whom we quote, that it would be. The wiring of a man-of-war which at a critical moment can be kicked asunder by a clumsy fireman would certainly cause or intensify a calamity sooner or later. We wish, the journal adds, that we could persuade ourselves that such abominable work were confined to Spanish ships of war—but we can't. The opportunities for improvement in all electrical work afloat are very numerous and extensive.

Kapp on Double Voltage.—Mr.-Herr Kapp has a leader on the subject of the increased pressure at St. Pancras in the latest number of his journal, the *Elektrotechnische Zeitschrift*. He comes to the conclusion that

Digitized by Google

"the doubling of the voltage in existing three-wire systems presents no difficulty, for with the excellently-insulated cables which are used in Germany 200 volts are not more dangerous than 100 volts. The same may in most cases be said also of the lamp switches and safety devices, so that the general introduction of the double pressure, and with this the possibility of a distribution far beyond present limits, depends simply and solely upon the question whether it will be possible to produce really reliable and economical lamps for 200 volts. This is a question whose answer must be left to the future. We shall, however, soon have, at any rate, a partial solution of the problem from the experiences in St. Pancras"—and Bradford!

The Magnetisation of Iron.—Prof. K. Zickler, of Brünn, has a lengthy article with this title in the October number of the *Zeitschrift für Elektrotechnik*. He says that among the magnetisation curves resulting from the various forms of electromagnets, those which are known as normal magnetisation curves have in the last few years become of great practical importance, since they are used as the basis for the calculation of magnetic circuits. He refers by way of example to the process of Messrs. J. and E. Hopkinson for estimating the magnet winding in dynamos. Owing to its use in the solution of practical problems, the study of the laws governing these normal curves has assumed a particular importance. Prof. Zickler has been investigating the subject for some little time, and he has succeeded, with an approximation sufficient for practical purposes, in ascertaining these curves in their whole extent, both calculably and constructively, when the co-ordinates of an accurately fixed point of the curves are given.

Thermodynamics.—At the City and Guilds Technical College, Finsbury, Leonard-street, City-road, E.C., a special course of four lectures on the principles of thermodynamics and their application in engineering will be delivered by Prof. John Perry, M.E., D.Sc., F.R.S., on alternate Thursday evenings, from 7.30 to 9 o'clock, commencing on Thursday, October 24. Students are supposed to be already possessed of some knowledge of heat and thermodynamics, and also of the differential calculus. I. October 24.—How we calculate exactly the heat and work changes when any changes of volume pressure or temperature occur in stuff subjected only to fluid pressure. II. November 7.—The first and second laws of thermodynamics. III. November 21.—Application to air-engines and especially to gas-engines; also to compressors, exhausters, and refrigerators. IV. December 5.—Application to the steam-engine. One or more additional lectures may be necessary, and, if so, their dates will be announced later. The fee for the course is 4s.

The Measurement of High Temperatures.—Mr. J. McCrae describes in *Ann. Phys. Chem.* a small thermo-electric element which he uses for the determination of temperatures varying from 300deg. to 1,400deg. It consists of a junction of platinum and platinorhodium, and the author states that between the above limits the E.M.F. is approximately proportional to the temperature. By its means the following melting points were determined:

	Deg.		Deg.
Sodium iodide	694·7	Strontium chloride...	853·7
Potassium iodide ...	722·7	Sodium carbonate ...	856·7
Potassium bromide...	745·5	Sodium sulphate ...	881·2
Sodium bromide.....	761·1	Potassium carbonate	887·5
Calcium chloride ...	802·1	Barium chloride.....	915·6
Potassium chloride...	803 9	Potassium sulphate..	1,058·9
Sodium chloride.....	811·0		

The boiling point of stannous chloride was found to be 603·25deg., whilst the temperatures of an alcohol flame and the blue point and the hottest part of a Bunsen burner flame were determined as 1,488deg, 1,542deg., and 1,725deg. respectively.

"Harnessing the Tides."—Now that the current of Niagara has been utilised for generating electricity, it is not surprising to find a writer in the *North American Review* insisting upon the old-new theory that we must "harness the tides." "The tides of the North and East rivers," he says, "produce power enough to generate all the electricity required to light New York and Brooklyn, to do all the mechanical work in the factories and machine shops, and to run all the railroad lines in the city and suburbs. . . . All that is required is to store this immense power, and to turn it to profitable use." If the tides would not give a constant supply of power, they would, it is argued, vary less than the inland rivers in summer-time, and generating plant suited to the purpose could no doubt be easily designed. The writer fears that unless New York, Brooklyn, and the neighbouring cities begin to utilise the water power at their doors the Niagara Falls Power Company will want to run an electrical conduit to New York. As "a conduit capable of bringing from 100,000 h.p. to 200,000 h.p. from Niagara would cost more than a four-track steam railway," he thinks the money required might more profitably be spent in New York itself, where the demand for electric power is increasing very rapidly.

Photography by Electric Light.—Mr. Moffat, an Edinburgh photographer, gave a demonstration in his studio recently, before a numerous audience, of a new system of photography by means of the incandescent electric light. The apparatus is the invention of a Mr. Adamson, of Glasgow. It consists essentially of a series of 20 incandescent lamps of 100 c.p. each strung round the inner edge of an umbrella-shaped frame which is covered with white silk. This umbrella is fastened by a universal joint to a beam like that of a steelyard which runs on rails suspended from the roof, and has also a universal joint, so that with a touch of the hand the light can be run from one end of the studio to the other, and adjusted at any angle. The light, it is stated, is under perfect control, and the switch is so arranged that the lamps can give any light up to 2,000 c.p. Mr. Moffat explained the manner in which the apparatus was worked, and several excellent negatives were taken. One of the drawbacks which made the arc light a failure in photography was, Mr. Moffat said, the harshness of contrast in the lights and shadows, but with the incandescent light this difficulty was overcome. In the negatives which were taken by way of demonstration the shadows, it was shown, could be further toned by adjusting silk screens between the light and the sitter. The finished specimens of electric light photographs which were on view were found to be as soft and delicate as any daylight photographs.

The Position of Telegraphists.—An Irish correspondent writes: "Discontent with the present condition of affairs, and the utterly hopeless prospect, has reached an acute stage in the telegraph service. Every steamer leaving Southampton for the Cape has on her passenger lists the names of operators from every important office in the Kingdom—the flower of the telegraph service—who, in sheer disgust, have thrown up their Government appointments and accepted lucrative and responsible offices in South Africa. Some years ago Cork contributed its quota to the tide, and now these gentlemen are urging their erstwhile colleagues to join them in the 'Dark' Continent. In response to a communication (which has not yet received official recognition), asking for a dozen men for service in South Africa, more than that number of Cork men alone are candidates; but their claims are hard pressed by the

Digitized by Google

numerous applications from operators in London, Liverpool, Manchester, Glasgow, Limerick, Dublin, and other centres anxious to exchange badly paid British Government telegraphistships for remunerative salaries elsewhere. The avidity with which the telegraphists of the United Kingdom are snapping up foreign appointments throws rather a curious light on Mr. Arnold Morley's statement that those in the service are quite content with their lot, and will furnish useful data with which to confound that statement before the committee of enquiry into the telegraph and postal grievances." It is not often that an Irishman is found who denounces the alleged injustice suffered by a class of Englishmen.

"The Truth about Foyers."—A "special correspondent" of a Dundee paper has visited the Falls of Foyers, and duly chronicled the results of his observations and enquiries. He entitles his communication, "The Truth about Foyers: A Revolutionary Scheme of Progress." The district "has for more than a century been the joy of the tourist and the pride of the native," but a change has come over it. "For months blasting and dynamite have been the predominant factors of the situation, the roadways, swept by fragments of broken rock, afforded no security for sightseers, and the steamers—save an occasional one—have ceased to wait. . . . The crack of the mason's mallet mingles with the clang of the blacksmith's hammer, as workshops, dwelling-houses, sheds, and offices rear themselves from the base to the summit of the hill." We are told that "in future Foyers is to be celebrated not only for its magnificent falls, but for its gigantic aluminium works." It is added that "the time for staying this movement is past; the hands of the clock are too far round ever to go back. More than 400 workmen of all kinds are at work, and plant worth from £40,000 to £60,000 has been laid down." The correspondent was conducted over the works by a "courteous official," who, in reply to an enquiry as to the probable fate of the falls, said: "The engineers could probably tell you better than I can, but the scheme of the company is, I think, designed to improve the appearance of the falls—certainly to make the flow more uniform." So far so good.

Electric Clocks.—Mr. F. Hope-Jones, with whom was Mr. G. B. Bowell, delivered a lecture on Wednesday last at the British Institute of Horology, Northampton-square, E.C., on the subject of electric clocks. The lecturer described in detail, with diagrams, the system of the Synchronome Company, in which an electrically-driven pendulum controls a set of dials also driven electrically, the movement consisting essentially of an escapement driven by two pallets so linked together that one gains on the other, either circumferentially or radially, during a part of its cycle, in order to pass the dead centre. The energy is derived from an electromagnet and a dry cell, and it is an essential part of the system that the mechanical force driving the hands is transmitted by a pushing action through the points at which the electrical contact is made and broken. False or double contacts, which would set the dials wrong, are thus avoided. The duration of the contact is about one-fortieth of a second. For commercial purposes the whole of the dials are synchronised by the pendulum every quarter minute. For this purpose the set of dials are connected in series, and provision is made for regulating them all at once without stopping the pendulum; one dial, for instance, being arranged so that if it is set back all the others of the set are switched out and wait until it comes into synchronism with them, when the original connection is re-established. This system is available for all sizes short of turret clocks. A system for the latter was also described, in which a motor was used with a device for picking up losses due to a temporary failure of the motor. A discussion followed.

The Electro-Harmonic Society.—A smoking concert will be given by this society on Monday, October 21, at the St. James's Hall Restaurant (Banquet-room), Regent-street, W., at eight o'clock. The artistes will be: The "Lyric" Vocal Quartette, Mr. Thomas Powell, Mr. Charles Strong, Mr. Etherington Smith, Mr. Horace Reynolds, Mr. Daniel Price; recitations, Mr. Ernest Meads; humorous sketches, Mr. George Schneider; silver bells, Mr. R. B. Hopkins; at the pianoforte, Mr. Sidney Hann. The musical directors are Messrs. T. E. Gatehouse and Alfred E. Izard. The following is the programme—Part I.: quartette, "Annie Laurie" (Anon), the Lyric Vocal Quartette; song, "Ailsa Mine" (Newton), Mr. Charles Strong; pianoforte solo, "Fantasie Impromptu" (Chopin), Mr. Sidney Hann; song, "Oh! Hear the Wild Winds Blow" (T. Mattei), Mr. Daniel Price; recitation, "Julius Cæsar," Act 3, Scene II., Antony's Oration (Shakespeare), Mr. Ernest Meads; silver bells, "The Holy City" (Adams), Mr. R B. Hopkins; song, "Stars of the Summer Night" (B. Tours), Mr. Etherington Smith; humorous sketch, Mr. George Schneider. Part II.: Plantation melody, "The Old Folks at Home" (specially arranged), the Lyric Vocal Quartette; song, "The Bedouin Love Song" (Pinsuti), Mr. Horace Reynolds; silver bells, "The Promise of Life" (Cowen), Mr. R. B. Hopkins; song, "Aubade" (Cowen), Mr. Thomas Powell; recitation, "How Mr. Smiggles Went to a Public Dinner" (Turner), Mr. Ernest Meads; song (Irish), "Biddy Aroo" (Maitland), Mr. Daniel Price; humorous sketch, Mr. George Schneider.

Horseless Carriages.—The description and illustration of the Jeantaud electric carriage, which appears on another page, will have peculiar interest in view of the exhibition of horseless carriages which was held on Tuesday on the showground of the Tunbridge Wells Agricultural Society, under the superintendence of Sir David Salomons. Two carriages driven by Daimler motors, a tricycle also propelled by a motor worked by petroleum spirit, and a "steam horse" were shown in operation. The "steam horse" was quite out of the running for honours. It gave forth a good deal of steam at times, was noisy, and dropped burning cinders. The two carriages were both from Paris. Complaint was made of the vibration set up in them. There were no electric road vehicles tried. Curiously enough, a paper has just been read before the Society of German Tramways and Light Railways Administrations (Verein deutscher Strassenbahn- und Kleinbahnverwaltungen) by Regierungsrath Köhler, of Berlin, in which the author unfavourably discussed the gas car or carriage. He holds the working cost of 18pfg. (2·16d.) the kilometre ($\frac{5}{8}$ mile) to be very high, and far exceeding that of the average horse tramway, and he laid stress on the drawbacks of the gas-car—the penetration of street-dust into the bearings and cylinders of the engine, the heavy vibration, smell of gas, and the impossibility of having the windows open on the weather-side of the car. Electrical working was, he said, much to be preferred. Again, during the trial run the other day of a tramcar fitted with a new oil-motor at Glasgow, the oil-tank was set on fire, and the car was burnt in the centre of the street. Forty passengers, mostly town councillors, left the car in safety.

The Electric Punkah Question has again been raised in India. A correspondent writes to *Indian Engineering*: "In last week's daily papers there is an account of a new electric punkah-pulling machine. In describing the apparatus we are informed that the inventor contends that, to get an efficient punkah-pulling machine, the punkah

Digitized by Google

must give time to the machine and not the machine to the punkah. It is no new theory, for this was demonstrated in your journal over three years ago. There are over 120 patents for punkah pullers, and yet none have come into general use. The jerk seems to be the rock upon which most inventors get wrecked, and to obtain this some most extraordinary devices are resorted to. One of the simplest machines I have seen is Agabeg's puller. The inventor gets his jerk by the use of a flywheel on the shaft of the prime mover, and regulates the machine to suit the punkah by a sliding weight in the horizontal lever, to which the rope is attached. For a given punkah, once the weight is fixed it wants no more adjusting. I have seen one of these machines pull for hours without the variation of a single stroke, and the jerk is the same as that given by a coolie. The one I allude to was worked by a small Robinson hot-air engine of 4in. cylinder, and heated by a Vaguer stove. It took about 15 minutes to get up power and then ran eight hours, or until the oil in the reservoir was exhausted. This machine worked a 7ft. punkah, 24 strokes a minute with a 4ft. stroke. I also saw one of the same inventor's machines worked by electricity with the same excellent result." The correspondent adds that so long as the coolie is cheaper than the cost of working a machine puller, there is no chance of their ever coming into general use. He nevertheless thinks that, in a place like Calcutta, if electricity be laid on in the houses the same as gas is the machine "may get a look in."

Electricity in Mining Operations.—The advantages inherent in the electric explosion of mining charges will be generally recognised. It permits of an absolutely simultaneous explosion of several charges, which is always desirable from the point of view of the destructive effect produced, and at the same time it avoids the loss of time brought about by consecutive discharges, particularly when they have to take place in badly-ventilated workings, from which the smoke and gases produced by the explosion can only be cleared out very slowly. Besides, there is no danger from misfires, and the workings can be immediately approached without fear of the delayed explosion, which is always a possibility with powder fuses. Moreover, there need be no danger from firedamp, or from the act of firing the fuse. All these reasons, M. P. F. Chalon, writing in *L'Electricien* of October 5, thinks, will favour the use of electric fuses. Unfortunately, however, they are very expensive. In France wire fuses cost 300f. a thousand, and the discharging apparatus comes to 400f. or 500f. High-tension or spark dischargers are a little more economical, but it is not easy to determine previous to the explosion whether they are in perfect order, and it is necessary that the insulation of the conductors should be absolutely perfect. M. Chalon then goes on to describe a cheap American discharger, which he strongly recommends for adoption in fiery workings in French collieries. The discharger consists essentially of a magneto-electric machine driven by a rack and pinion, so that the action is very much like that of a garden hand-pump, an intermediate gear being provided to give the necessary speed. A discharger of sufficient size to produce 20 or 30 simultaneous explosions weighs 13 kilogrammes (about 28lb.), including the strong wooden case. It is designed to work with fulminate detonators up to a distance of about 500 yards. It is tested by connecting up to the terminals a small specially-constructed incandescent lamp. A separate apparatus is required to test the fuses and line. A current is sent through the line, not strong enough to heat the wires of the fuses, but sufficient to ring an electric bell if the circuit is in good order and complete. An arrangement is provided for adjusting the current to the number of fuses in circuit.

Advances in Electrotherapy. — The American Electrotherapeutic Association has just completed its fifth annual meeting. This year it met in Toronto, and while, Mr. J. Henderson writes, the attendance of members was not so great in the Canadian city as was expected, and the amount and value of the work done was not quite up to the standard set by the former meetings, yet many creditable papers were presented, and the discussions were lively and interesting. Five years ago electricity, as applied to medicine and surgery, was in a very chaotic condition. There was no uniformity in appliances or practice, no instruments for exact measurement, no facilities for obtaining the needed preparation for the practice of electrotherapeutics, no exact information regarding the appropriate use for the various forms of electrical energy in the treatment of disease. A radical change has been wrought in this state of things by this association. In the beginning, it promptly set itself about clearing the ground of chaff and rubbish, and developing a science of electrotherapeutics out of the solid facts which physics and physiology had to offer. Certain men, whose experience had taught them the value of electricity as an aid in checking the ravages of disease, had the courage of their convictions and did not hesitate to flood with the light of pure science their field of operation. Men eminent as electrical engineers and teachers of physics were invited to join them to aid in separating the sound from the unsound, the true from the false, in that which had been taught and practised as electrotherapeutics. By their aid a foundation of solid fact has been established, and charlatanism, which has long been in possession of this valuable territory, has begun to lose ground, and the claim of electricity, as a factor in therapeutics, has begun to receive respectful attention from medical educators and able practitioners the world over. The machinery through which this association has been able to effect this result in so short a time has been the establishment of standing committees composed of competent men, some practitioners of medicine or surgery, others not, whose duty it is to examine, test, and annually to report upon the mechanical construction, electric action, and efficiency, and the physiological and therapeutic effects of the various instruments designed and recommended for therapeutic work. The work of these committees continues the year round. Manufacturers have welcomed and aided their efforts, and the result has been a steady progress towards simplicity and uniformity in the appliances produced, and a greater unanimity in the results reached in practice. By this plan, the writer adds, the progress of electrotherapeutics is made to keep pace with the rapid strides in electrical science, and every discovery in methods of generation and transformation of electric energy finds therapeutic application, when this is possible.

An Interesting Long-Distance Power-Transmission Plant is in course of construction at Fresno, California, which is unique in more than one particular. The head of water to be used is 1,410ft., and the distance of transmission about 35 miles. The natural conditions surrounding the installation are extraordinary in themselves. The water for supplying the power is taken from the North Fork of the San Joaquin river. The stream of the North Fork runs for several miles down a rocky canyon, forming rapids and cataracts as it runs between the steep mountains. At the head of the rapids a canal will take the water out upon the summit of a high ridge, which it will follow for six miles to a point nearly 1,500ft. above the San Joaquin river. Here a reservoir has been constructed with an average depth of 10ft. It covers about

Digitized by Google

eight acres, and can be made both larger and deeper should the demand for power require an extension. Into this reservoir the water brought along the ridge by the canal will be stored, but it will be used solely as an emergency reserve. It is calculated that it will hold enough water to drive the machinery for several days, so that should a break occur between the reservoir and the source of supply the electrical work could continue until the repair was effected. A pipe line runs directly from the canal, a distance of about 4,000ft., to the power-house, and the head of water obtained will not be less than 1,410ft. The pressure at the bottom will be 600lb. to the square inch. The lower end of the pipe line is of welded steel pipe, $\frac{3}{4}$in. in thickness, having special steel flanges and special packing at the joints. The lowest amount of water power available is at least 7,000 h.p. at the head above mentioned. All possible accidents are provided against. Should a break occur near the lower end of the pipe, the rush of water would form a vacuum near the upper portion of the pipe and it might collapse under atmospheric pressure. An air-valve will be placed near the top to provide against this contingency. The pipes will be made in sections of 20ft. each. At the upper end the metal will be $\frac{1}{4}$in. thick and the pipe 24in. in diameter. It will be fastened to the granite mountain sides by steel cables. The power station will be located at the bottom of the mountain and will contain three Pelton waterwheels, 58in. in diameter, driven by a single nozzle. The generating plant will consist of three 340-kilowatt General Electric three-phase machines. From the point in the North Fork of the San Joaquin river, where the water is taken to the power-house at the foot of the mountain, is a distance of about seven miles. From the power-house to Fresno, where the electricity will be utilised, is about 31$\frac{1}{2}$ miles in a direct line or 35 miles over the electric wires. The line will consist of two circuits of bare copper wire, consisting of six wires strung on poles 40ft. high. The current will be delivered to the lines at a voltage of 11,000. From the power-house the line will rise to the level of the San Joaquin, cross it and pass through a portion of the Auberry valley, then rising over the Red Mountain, passing about a mile west of Clovis, will continue direct to Fresno. The first five miles will be over moderately level country, the other 30 through an open and practically level country, under ideal conditions for transmission. It is estimated that the power which will be delivered in Fresno at present from the three-phase generators will not be less than 900 h.p. At the Fresno end the line will be brought into a sub-station and the current will be transformed down. From the sub-station power will be delivered to all the mills in the town, the waterworks, machine shops, planing-mills, laundries, printing-presses, elevators, packing-houses, etc. It will also be used to drive the street railway system of the city, which will require about 300 h.p. In the sub-station two arc dynamos, each of 60 lamps capacity, will be driven by an induction motor, the motor being mounted on the same bedplate as, and being directly connected to, the dynamo. Current will be supplied for 4,400 incandescent lamps.

New Standards of Length at Mason College.—There has recently been laid down in the yard between the Science and Medical Schools of Mason College, Birmingham, a series of exact standards of length, the longest being 100ft. The series of lengths marked is—

4in.	$6\frac{2}{10}$ft.	10ft.	33ft.	50ft.	66ft.	100ft.
100mm.	2m.	3m.	10m.	—	20m.	—

There are thus seven lengths marked in English units and five in French units. They are defined by fine lines scribed upon the polished horizontal surfaces of hard gunmetal plates. These are leaded into recesses cut in the upper surfaces of large blocks of the Welsh sandstone grit called "Minerva." The plates were first carefully bedded in these recesses, and then, after the lead was poured and cold, it was hammered up hard with hammer and punch. The stones are 10in. by 10in. at their upper surfaces, their bases, about 14in. square, being from 16in. to 20in. deep. They are a remnant of a quantity of stone employed round the doorway of the bottom entrance to the council house, nearest the Town Hall, and had been kept seasoning in Messrs. Barnsley and Sons' storeyard for 15 years before being used. These blocks are bedded upon Portland cement concrete 9in. deep, and the concrete is built up to the surface monolithically round each stone a thickness of 10in. to 12in. The foundation of this yard is itself a concrete almost as hard and solid as are the newly-set monolithic masses, which are each about 2ft. 6in. to 3ft. square by 2ft. 3in. deep. This part of the work was done by Messrs. Barnsley and Sons, and the gunmetal plates were supplied by Messrs. Hunt and Mitton. For the protection of the plates, each is covered by a stout brass plate easily removed by merely loosening one screw, and each stone block is covered by a large wooden block to prevent barrows and carts being taken over it. The lengths were transferred from a 100ft. steel tape. The marks on these steel tapes are coarse, but each mark has its two edges fairly sharply defined, and the measurement was in each case taken from the centre between these two edges. The tape was sent to Kew Observatory to have its errors at the places to be used tested. These errors were then measured at recorded temperatures, and under a constant pull of 3lb. applied to the tape. The tape was then stretched across the college yard with precisely the same pull kept constant throughout the whole work of marking off. The work of marking off was done by Mr. William Mavitta, of 88, Aston-street, Birmingham, and Prof. Smith left entirely in his hands the determination of the method to be followed. Mr. Mavitta has done this work free of charge, out of love of his special work, and for the benefit of the college and the town. A fine steel wire was stretched across the series of blocks, and from this the scribed cross-lines were squared off. The actual marking off was done by help of a micrometer screw instrument specially designed and made by Mr. Mavitta for this occasion, it being graduated to 1-1000th of an inch. For each mark the error as found at Kew, due correction being made for change of temperature, was measured off by help of this instrument from the exactly-measured centre of the line on the steel tape. The instrument then immediately made the mark upon the gunmetal plate. The temperature through this marking was higher than that at which the tape had been tested at Kew. Mr. Mavitta was assisted by Mr. H. M. Waynforth in the calculation of the temperature corrections. Prof. Smith feels confident that no error of so much as one-hundredth of an inch occurs in any of the scribed lines. Unfortunately, the yard is not a dead level, so that the 100ft. block stands 11$\frac{1}{2}$in. higher than the others. Up to 66ft., however, the line is practically level. The cost of this work has been considerable, and has been defrayed partly by the college and partly by subscriptions from Messrs. Matthew and Son, Lea and Thornberry, Heuman, Rabone, J. Cossins, R. Godfrey, the Architectural Association, and Prof. Smith. The college council has given authority to allow engineers, surveyors, architects, and instrument-makers to test their chains and other instruments on these standards free of charge during the present year, and until other regulations may become necessary. They are, it is stated, the only accurate standards of long length existing in the Midlands.

PHASING TRANSFORMERS.*

BY CHARLES S. BRADLEY.

The polyphase motor is so good as to need but very little, if any, improvement, but this is so familiar to the institute that I need not go into details. I think the time is not far distant when we shall be able to fill out with the alternating currents any engineering problem that may be required of us. We will be able to take old plants and modify them to do any work which may be necessary. One of the important links to round out the art seems to be the phasing transformer, so that we can take a single-phase alternating current and convert it into polyphase of any desired number.

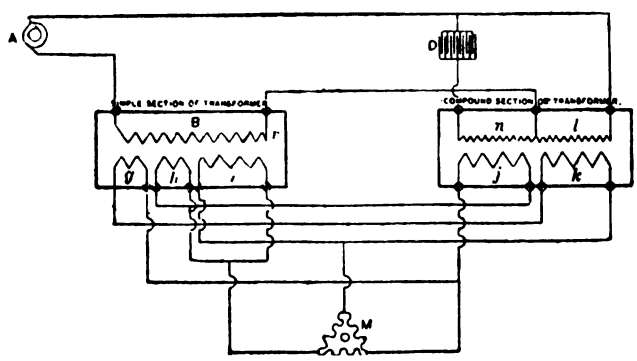

FIG. 1.

I have chosen for my work the conversion of single phase to three phase, because the three-phase motors which we have been able to construct give us very much less trouble than the two-phase. In a series of experiments, I have found that the two-phase motor would run at a number of speeds, especially when supplied with current from a phasing transformer. I suppose the trouble arose from harmonics, but of this I am not certain. The triphase motor never has given us any of this trouble. These experiments, however, were carried out before the transformers had been refined; and, now that we are getting more perfect results, I think it is very probable that we could return to the two-phase motor and get much better results than when first tried. The following is a description of an arrangement of condensers and cores to produce polyphase and single-phase alternating currents. Many different arrangements of condensers and inductances have been tried, and all have failed to keep their phases at a working relation, except the one I am about to describe.

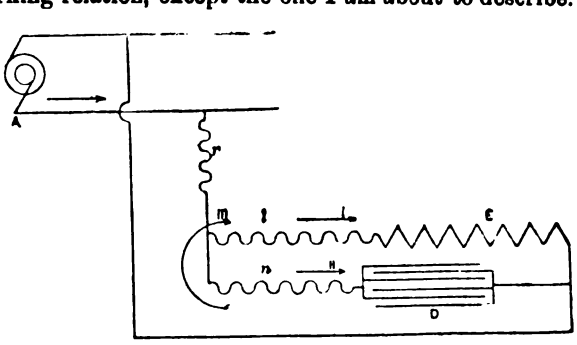

FIG. 2.

A diagram of the phasing transformer and connections with the generator and motor will be found in Fig. 1, A being the generator, B the simple section of the transformer, D the condenser, and M the motor; r, primary of the simple section of the transformer; n and l, primary of the compound section; g, h, and i, secondaries of the simple section of the transformer; and j and k, secondaries of the compound section. The primary of the simple section of the transformer is in series with the compound section and condenser. By the proper adjustment of capacity and inductance, the magnetic flux in the core of the compound section is approximately 90deg. in phase behind the simple section; then, in order to get three phases from the two, I resort to resultants in the secondaries: g and k constitute one phase, h and j a second, and i the third. The essence of this invention rests in the arrangement of the compound section of the transformer and condenser. In order to explain the theory involved in this, refer to Fig. 2, in which A is the generator, E the inductance, D a condenser or capacity, l and n represent the leads to the inductance, E, and to the capacity, D. If the generator is generating an E.M.F. in the direction of the arrow, Fig. 2, a current will flow through the lead l and the inductance, E, as represented by the arrow I., and through n into D, in the direction of the arrow II., as indicated by the curves in Fig. 3—that is, during the rise of the E.M.F. through the machine from the point o to the top of the wave at p, the current will flow in parallel into or through the inductance, E, and the capacity, D

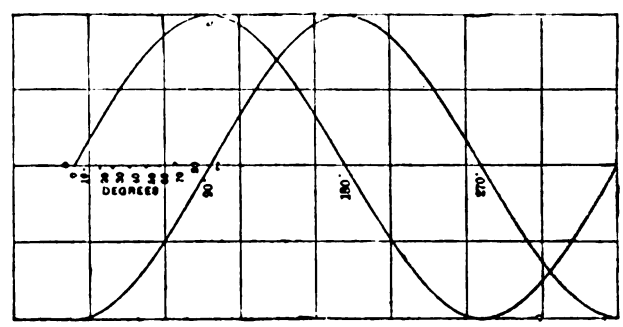

FIG. 3.

(Fig. 2). As soon as the wave of the E.M.F. commences to decline from the point p the condenser will begin to discharge, and the current flowing from it will be in the direction of the arrow III. (Fig. 2). Also, at the same time, the inductance will discharge its energy by a current in the direction of arrow III., so that the current represented by arrow III. will cross the zero line at point t (Fig. 3) or is delayed by a time equal to 90deg. Thus, we see that the current represented by arrow III. will be lagging in its time period considerably behind that in the lead r, represented by curve op. Now, if we wind the lead l and the lead n upon an iron core, as shown in Fig. 4, in opposite directions and of the same number of turns, and have the inductance, E, bear a proper relation to the capacity, D, so that the currents represented by arrow I. and arrow II. shall be equal, no magnetic flux will be produced in the core during the rise of the potential of the machine from o to p on the curve, but during the fall of the E.M.F. of the machine, and during the discharge of the inductance and condenser which is represented by arrow III. (Fig. 2),

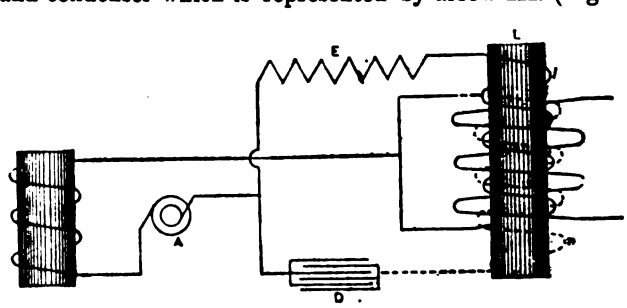

FIG. 4.

the currents flowing through n and l will be in series and flowing in the same direction; consequently, the magnetic flux will be approximately 90deg. later than it would be if charged directly from the machine. I have represented in Fig. 2 a section of lead by r, and it will now be clearly seen that the current in the lead r will have a phase difference from the combined or resultant phases in the leads l and n. Furthermore, a current in the lead r will be in lead of the E.M.F. of the machine, because the inductance and the condenser, previously described, cut off the flow of the current before the machine has reached the zero point, and when the lead r is placed upon an iron core, as shown in Fig. 4, it has a tendency to lag, which counterbalances the lead, and leaves the main line current somewhere near in phase with the E.M.F. of the generator.

* Abstract of paper read before the American Institute of Electrical Engineers, September 25, 1895.

Digitized by Google

Refer, now, to Fig. 4, where the leads *l* and *n* are wound in opposite directions, and completely interlaced upon the iron core, L, the generator, inductance, and capacity being indicated by the same symbols as in previous figures. The lead *r* is here wound upon the second iron core, which constitutes the primary of the simple section of the transformer, as shown at B (Fig. 1). In reducing to practice and applying the transformer to an induction motor, we find that the inductance, E, can be dispensed with, as the apparent inductance produced by the motor furnishes all the lag necessary; and it will be noted that in Fig. 1 the extra inductance which we used in our first experiments is left out of the combination. The lead from the simple section of the transformer, it will be noted, goes to the

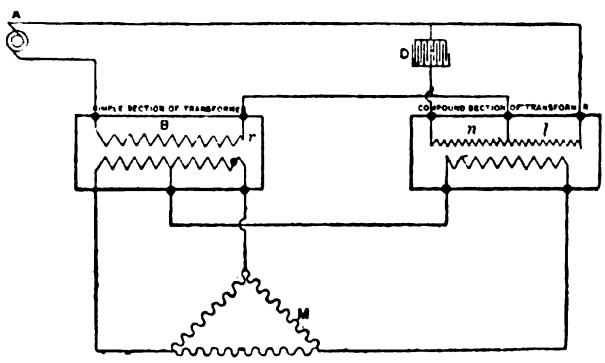

FIG. 5.

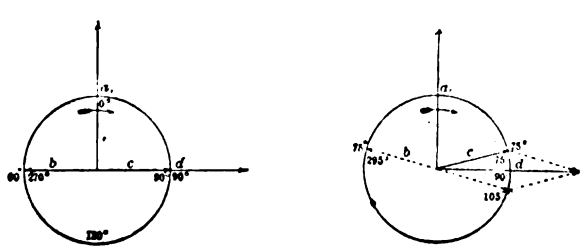
centre of the compound section. This diagram does not represent the true condition of the compound section, for the windings, *n* and *l*, are together, or, as before mentioned, interlaced upon the core. The magnetic flux in the two sections of the transformer are approximately 90deg. apart. The secondaries are therefore wound each partially upon the two cores, so that the three resultant phases may be produced from two, this being in accordance with Mr. Fred. S. Hunting's invention for changing two phases to three.

Mr. Scott's invention for changing two phases to three may also be used, and is shown in Fig. 5. Making the resultants in this manner by means of the secondary windings contributes also to steadiness of phasing. If desired, two secondaries having a proper two-phase relation may be used on the motor.

The experimental work, in which I have been greatly assisted by Messrs. Hulse and Chapman, has occupied a long time, and has passed through a great many stages. The ½-h.p. motor gives powerful starting torque. (The motor was shown in operation.)



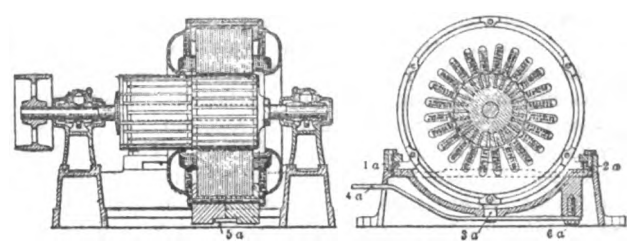
FIGS. 6 AND 7.

I want to bring to your attention one feature of the compound coil used in combination with the condenser, which will be found in Figs. 6 and 7. If we suppose a direction of motion as shown by the arrow and the current in the condenser branch leads by 90deg., which is represented at *b*, and the current in the inductance branch lags by 90deg., as indicated at *c*, and the wires carrying these currents are wound in opposite directions upon the core, we will have a resultant current, which is represented by extension *d*. Increase of load changes the phase relation of the individual branches, but not the resultant secondary, and this is explained by reference to Fig. 7, where a 75deg. lead and a 75deg. lag are represented by the respective branches, and, as the branches are wound in opposite directions, we find that when *b* is turned over it becomes a lag of 105deg., and the resultant of 75deg. and 105deg. again produce 90deg. lag, and the value again represented by the extension *d*, the value of the current is slightly less, but its resultant phase is the same as is represented in Fig. 6. This explains the steadiness of phasing which we are able to obtain.

The power factor is found to be very good. The current in the main line feeding the transformer varies from 10deg. lead at full load to 35deg. lag at no load, and the motor at starting produces the same effect as when working at full load, so that we have very good phasing for starting and full load, as well as a good power factor, it being 82 per cent. even at light loads, and the probability is that we will have very much better results upon larger-sized transformers.

The condenser in this combination fills two very important functions: first, assists in the phasing; and, second, prevents the lag upon the line. This arrangement does not prevent the idle currents flowing in the motor circuits, and the secondaries of the phasing transformer, and we find in small motors with the high period of 140 cycles that the apparent energy in the motor circuits is sometimes 2½ times the apparent energy in the main line. The capacity of condenser for a ½-h.p. motor when 1,000 volts are supplied to the transformer is about 2·4 microfarads. Our condenser for this size, without connections, occupies a space of a cube 4in. on each side and capable of enduring 3,000 volts, or a factor of safety of 4, as the voltage of the condenser is about 700. Of course, it will be understood by those familiar with the designs of induction motors that it is impossible to design a small motor with small power factor, as the air-gap necessary for mechanical construction has to be so large in proportion to the size of the motor.

Many attempts have been made by placing the condenser in direct connection with motors to produce rotary fields, but have so far been attended with little success; as the



FIGS. 8 AND 9.

trade requires the motor to be of comparatively low voltage, which calls for a large capacity in the condenser, and as the output of the condenser of a given capacity is proportional to the square of the voltage, it will be seen how advantageous it is to place the condenser in combination with the primary of the step-down transformer.

It may seem trite to call your attention to the fact that the transformer reduces the voltage at the same time it does the phasing, but I think it is so important that I wish particularly to emphasise the fact. It is also of great importance that the device has no moving parts.

While the principal use for this device at present seems to be the application of polyphase motors to single-phase lighting systems, many new ones, undoubtedly, will be found. It may seem bold to think of applying this to long-distance trolley railroads, but I am hoping to have it done. It is much more simple to have one trolley wire with track return, than to have two trolley wires which would be required by the direct application of polyphase systems. A large amount of power requires either a large current or high voltage, in order that the resistance of contact of whatever device is used to make connection to line need not be too great. As viewed at present, it seems as if the alternating current must be used for this work. If so, and unless the traffic is extremely frequent, it will take many more transformers, if they be placed along the line, than if the transformation is made upon the car or locomotive, because the transformers along the line, having no trains or cars near them, would be idle. If the voltage is stepped down on the car or locomotive, it is just as economical to do it by the phasing transformer, with the exception of the added weight of condensers, which for a 1,200-h.p locomotive will be about two tons, and this is not of consequence on so large a power.

Digitized by Google

Cuts of the motor are shown in Figs. 8 and 9, the rotary field being the exterior or stationary part, and the secondary or induced constituting the armature. The armature is composed of two sections, or practically two armatures end to end upon the same shaft, one of the armatures having a low-resistance winding, and the other a comparatively high resistance. The field is placed over a high resistance for starting, and shifted by means of a lever over the low resistance, when it has nearly attained speed. Of course, this arrangement is for securing the starting up of the motor, and has nothing to do with the phasing transformer, and the motor might have rings for connecting the starting resistance to the armature and operate quite as well. The sliding of the field gave trouble, as the air-gap has to be small, and the play at the sides noted 1*a* and 2*a*) allowed the armature to strike against the field, and when a tight fit was made, which would work easily when cold, it would stick fast when the motor rose in temperature; the writer therefore decided to give it quite a clearance at these points, and give it a guide at the bottom of the field (shown at 3*a*). This being central and comparatively thin, the expansion is not sufficient to cause sticking, also the guides at 1*a* and 2*a*, being thin vertically, they may fit close and still slide easily. The lever for moving crown back and forth is shown at 4*a*, Fig. 9, and 5*a*, Fig. 8. It fits loosely, having a fulcrum at 6*a*.

REGULATION OF ALTERNATING DYNAMOS.

BY W. L. R. EMMET.

The maintenance of a constant pressure at lamps is a problem of much greater intricacy on alternating than on direct current circuits, since there are more conditions to be considered. Good results may, however, be obtained with as much accuracy in one case as in the other if proper methods are used. The causes of error in a direct-current circuit are: (1) variations of pressure at dynamo terminals due to armature reaction and resistance; (2) variations due to resistances of lines. The variation in both cases depends solely upon the amount of current in the circuit. In an alternating circuit the same causes of error exist, and in addition we have variations of another class which are due to periodic E.M.F.'s of self-induction, introduced into the circuit through the dynamos, lines, or load. These E.M.F.'s are in quadrature with the current, and their effect upon regulation depends largely upon the ratio existing between their total amount and the amount of generated E.M.F. in phase with the current. Where the amount of E.M.F. of self induction is small compared to the E.M.F. in phase with the current, the effect of a given amount is less than it would be if the whole were larger in proportion to the E.M.F. in phase with the current. Thus, in order that E.M.F. of self-induction may influence a circuit seriously, it must exist in sufficient quantity to give character to the circuit. The effects of self-induction on a circuit may be illustrated by lines and angles.

In the two diagrams, Fig. 1, the length of lines, A B, represent E.M.F.'s in circuit which are in phase with the current. The lengths of lines, C B, represent E.M.F.'s of self-induction which are in quadrature with the current. The lines, A C, represent the generated E.M.F. necessary to produce the current flow. The E.M.F. in phase with the current represented by A B is alone effective in doing work. The lines, B D, being the difference between A C and A B, represents the increase of generated E.M.F. made necessary by the self-induction in the circuit, or the effect of the self-induction upon the regulation. No matter in what part of the circuit the self-induction exists, its effect on the generated E.M.F. is the same. Thus, in an alternator, the E.M.F. at the terminals is not the generated E.M.F., but is the resultant of the generated E.M.F., and the E.M.F. of self-induction in the armature. Thus, the E.M.F. which is shown by a voltmeter at the terminals of an alternator is not the true E.M.F. which is effective in the circuit, and may depart from it more or less according to the condition of inductance of the machine and of its load.

There is a wide difference in the degrees of self-induction of different alternators, but none is entirely without self-induction; thus, every alternator requires somewhat different regulation for inductive than for non-inductive load, the current never being in exact proportion to the losses to be compensated for.

The only practical method of adjusting the generated E.M.F. of an alternator is through variations of its field strength, which may be accomplished either by hand, through adjustments of the exciting potential, or automatically, either by rectifying a portion of its current on a commutator and using it in a series winding, or by using some other device by which the excitation is increased as the load on the machine rises. Since, as we have shown, the required generator E.M.F. does not depend directly on the current, these automatic means of regulation must be more or less inaccurate. They are, however, of very great value, since they confine the variations to certain narrow limits, and make less frequent the necessity of hand adjustments, and also make the effects of neglect by attendants less harmful.

Alternators may generally be divided into two classes—namely, high-inductance machines and low-inductance machines. There are machines built and advocated by prominent makers which are typical of both these classes, and there are, of course, others of all degrees of inductance between these extremes. Both these types have certain inherent merits and defects. It will be well to explain here that the degree of self-induction or inductance is not the only feature which distinguishes the two types of machines, but that it is, incidentally, more or less characteristic of them. In the machines which we classify as of high inductance a comparatively large number of turns are used on the armature to each field pole, thus making the magnetic flux for a given E.M.F. small. This

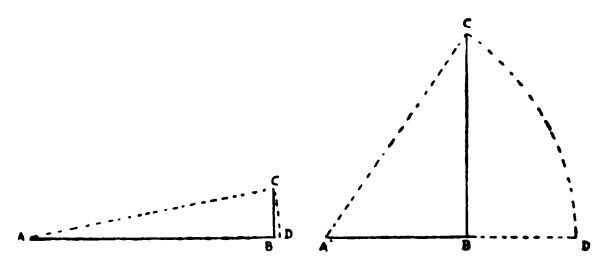


FIG. 1.

construction gives a large demagnetising effect of armature on field. The massing together of these armature-turns in large slots gives rise to more or less self-induction; this, however, is never excessive in well-designed machines. The types of machine which we have classified as of low inductance have relatively few armature-turns per poles, generally less self-induction.

Since the design of the machine has an important bearing on its regulation, we will briefly review some of the peculiarities of these classes. The typical machine of high inductance has a slotted armature with one slot per pole, the slots are large, and are filled by coils of many turns of wire. The inductance of such a machine is increased by making the slots deep and narrow, by extending the teeth over the coils so as to reduce the magnetic reluctance around the coil, and by increasing the number of ampere-turns per coil in the armature. Reduction of the air-gap may, in some machines, increase the self-induction appreciably. The advantage of machines of this class are:

1. For a given cost they may be made much more efficient than machines of low inductance. This difference in efficiencies is particularly marked at light load, since the principal saving in the high-inductance machine is through core loss and exciting current, which losses go on at all loads.

2. The machines are adapted to safe operation in parallel, since the current cannot rise to a dangerous degree if the machines are thrown out of step.

3. For the same reason the machine cannot be injured mechanically or otherwise by short-circuits.

4. The structure is simple, the space occupied by insulation being small, and the coils few in number. The principal disadvantage of machines of this type is that their inherent regulation is not good—that is, a wide variation of field strength is necessary for different loads. This variation is

Digitized by Google

usually provided by compounding the field with rectified current from the armature circuit. This commutation, which in some machines is a matter of serious practical difficulty, is somewhat facilitated in machines of this class by the fact that the total power required in the field is small.

Many different types of low-inductance machines have been used to a considerable extent; they are, however, much less used now than formerly. Among them may be mentioned the flat-coiled, smooth-body machines once in general use, also the various machines built without iron in the armature, like the Faranti, Mordey, and Brush types. A more modern form of low-inductance machine is built with an armature having many small slots with distributed windings. In such machine the self-inductance may be made low at low current ratings, and if the ampere-turns per pole are kept low, the inherent regulation may be made close. Such results can, however, be obtained only at the expense of material and of efficiency. The expense of such machines is greatly increased when they are built for low frequencies. The main advantage that can be claimed for any of the machines of this class is that they may be made to regulate within comparatively narrow limits without compounding, or that they require, if compounded, a relatively small amount of series field. It will usually be found, however, that to get this regulation without undue expense, the iron is run near saturation, and that proper compounding is impossible. One of the greatest disadvantages of such machines is that they are unsafe in case of short-circuits, or when used in parallel.

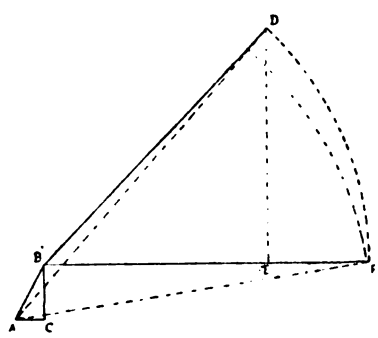

FIG. 2.

The field being intense, and usually partially saturated, and the armature-turns being few in number and of low self-induction, the demagnetising effect of the armature is small, and there is nothing to check the flow of current. The result is that when short-circuits occur, armatures are stripped, shafts are twisted, and belts, or flywheels, or engines are broken.

The ideal alternator is one having a moderately high armature reaction with its iron worked well below saturation, and with its field compounded to suit the conditions of its operation if automatic regulation is desired. A moderate amount of self-induction cannot be avoided in such machines, and is not objectionable. By a suitable proportioning of the slots the self-induction is kept within the proper limits. Such a machine is safe and stable under all conditions; it has a straight compounding curve, a high efficiency, and a small exciting current.

No matter what the design of a machine may be, it must always require a considerable field variation for different loads; the amount of this variation is widely different in different machines. Machines of high armature reaction and self-induction may require twice or three times the field excitation at full load that is needed at no load for a given E.M.F. In some machines of extreme design there may be as little as 5 per cent. difference between the full load and no load excitation if the load be non-inductive. The best modern alternators require from 30 to 60 per cent. increase in field excitation between no load and full non-inductive load.

It has been partly explained in the beginning of this article that the character of the load has an important bearing on the regulation of a dynamo. If the load on the dynamo be non-inductive, the effect of the armature self-induction upon regulation is slight; if the load be inductive, the effect of armature self-induction is greater, it being necessary to generate a greater E.M.F. in order to get a given E.M.F. at the dynamo terminals. This may be illustrated by a figure.

Let the length of the line A C represent in any desired unit the volts lost in the armature due to consumption of energy in heating the wire, core, etc.; let B C represent the volts lost in armature in overcoming the counter E.M.F. of self-induction; let B F represent the volts required at the terminals of a load having no self-induction, and let B D, drawn equal in length to B F, represent the same number of volts required at the terminals of an inductive load. B E is the energy component, B D, and represents the volts in phase with the currents which are effective to do work. D E is the induction component of B D. The line A D represents in the units chosen the E.M.F. which must be generated in the case where the load is inductive, and the line A F, which is less than A D, represents the volts which must be generated in the case where the load is non-inductive. Thus, although the volts at the terminals of the machine are the same in both cases, the field for a given speed must be stronger in the case where the load is inductive.

The variation just described is prominent among the many causes of error which effect the regulation of alternating circuits. Its importance in recent times is continually increasing since we are beginning to have motors and arc lamps on our circuits which tend to give an inductive character to the load. It is not necessary, however, to have motors and arc lamps to get a considerable degree of inductance in alternating circuits during times when the load is light and transformers are being worked far below their ratio capacity.—*Electric Power.*

NEWPORT (MON.) ELECTRICITY WORKS.

The Newport central station was opened last Monday. We abstract the following from a printed description of the station kindly forwarded to us by the consulting engineer, Mr. R. Hammond, M.I.M.E. The Newport provisional order was obtained in 1891. Mr. Hammond was selected as consulting engineer and reported towards the end of 1893. His recommendations were adopted and specifications issued, upon which the following contracts were made:

Buildings—Including foundations for engines, boilers, alternators, etc., Messrs. William Gradwell and Co., Barrow-in-Furness.
Generating Plant—Boilers, mechanical stokers, pumps and heaters, steam and exhaust pipes, alternator and exciters, switchboard and instruments, day-load plant, Messrs. John Fowler and Co., Limited. Leeds.
Engines—The Uskside Engineering Company, Newport.
Distribution—Converters, culverts, arc lamps and posts, meters, Messrs. John Fowler and Co., Limited, Leeds.
Cables—Messrs. Siemens Bros. and Co., Limited, London.

The site was selected for convenience of water and coal supply. Current is supplied from the alternators at 2,000 volts, and transformed down to 100 volts. In the boiler-house is a battery of four Lancashire boilers. Each boiler is 28ft. long and 7ft. 6in. in diameter, with a grate surface of 36 square feet, and the flues 3ft. in diameter. The shell is of mild steel $\frac{2}{3}\frac{3}{2}$in. thick. Each ring of the shell is made in a whole plate with longitudinal seams, butt-jointed, and connected by double-covered straps. Hopkinson's fittings only are used. The working pressure is 125lb., but the boilers are capable of working up to 150lb. per square inch, and each boiler is capable of evaporating 4,500lb. of water per hour with the feed supply at a temperature of 60deg. F. The boilers are fitted with Proctor's mechanical stokers. Meldrum's system of forced draught is also fitted to the boilers. There are three duplex feed pumps, each capable of delivering 1,500 gallons of water per hour at a piston speed of 50ft. per minute. Three Berryman feed-water heaters are erected. The boiler-house plant includes one of Worthington's self-acting jet condensers, which when the engines are working condensing maintains a constant vacuum of 27in., and is capable of condensing the exhaust steam of 750 i.h.p. of engines working at their full capacity. The condenser has two high-pressure cylinders and two double-acting injection water plungers.

Digitized by Google

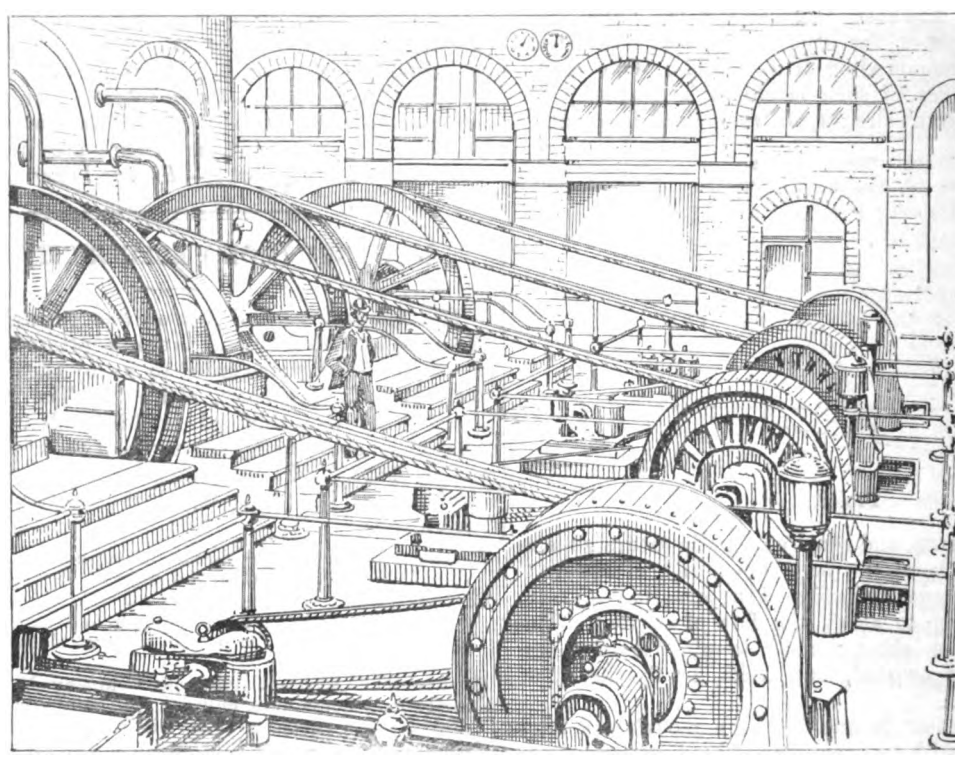
The engine-house is 93ft. long by 50ft. wide, and contains four 150-i.h.p. engines, four 75-kilowatt alternators, switchboard, temporary plant—viz., 100-i.h.p. engine and 75-kilowatt alternator, and an overhead travelling crane capable of lifting up 10 tons.

The engines are of the horizontal, compound, coupled, condensing type, and were manufactured by the Uskside Engineering and Rivet Company at their Newport works. They are arranged for working in conjunction with the separate condenser, and are each capable of giving off a continuous load of 150 i.h.p. The ordinary working steam pressure is 125lb., and the speed 110 revolutions per minute. In cases of emergency the engines are capable of working up to 180 i.h.p. by a slight increase in the steam pressure. The dimensions of the engines are as follow: high-pressure cylinder, 13in. diameter; low-pressure cylinder, 24in. diameter; length of stroke, 24in.; piston-rods, 2¾in. diameter; crankshaft, 7½in. diameter, increased to 9½in. at the flywheel; bearings, 7½in. diameter, 15in. long; crank-pins, 5½in. diameter, 6in. long.

The flywheels are 12ft. in diameter, and weigh over eight tons each. They are grooved for eight ropes of 1¼in. diameter. The expansion valves of both cylinders are controlled by Hartnell's vertical high-speed governors. The variation of speed when the load is suddenly switched on or off does not exceed 5 per cent. from friction load to full load. The following are the results of the official test of one of the engines carried out by the consulting engineer:

Total coal consumption	3,840lb.
Total water consumption	30,736lb.
Mean indicated horse-power	139
Consumption of water per indicated horse-power per hour	18·4
Consumption of water per kilowatt-hour	34·15
Consumption of coal per indicated horse-power per hour	2·3
Water evaporated per pound of coal from and at 212deg.F.	9·52

The alternators (Hall's patent) are driven by eight cotton ropes of 1¼in. diameter, each giving an output of 75 kilowatts, and capable of supplying current to 2,500 lamps of 8 c.p. A good margin for overloading is arranged for, each machine being capable of working for one hour up to 90 kilowatts. The speed is 525 revolutions per minute, and the mean speed at which the armature conductor is passed by the field magnets is about 7,000ft. per minute. The periodicity is 87 complete periods per second, and the E.M.F. 2,000 volts. The armature is stationary, with iron core of large section composed of charcoal iron sheets arranged longitudinally and in the same plane with the magnetic fields, clamped to the frame of the machine and thoroughly insulated. The armature conductor coils are formed of narrow copper tape, each wound upon a piece of insulating material of the same width as the tape, and rounded at the ends. The coils are thus of a flat link shape, the edges of the tape windings being exposed upon the flat surfaces of the coils, and therefore well able to resist deflection. These coils are placed close together upon the cylindrical inner surface of the armature ring, so that the axis of each coil is radial to the ring, and are secured to the same by strips of wood screwed to the cheeks, and extended over the ends of coil, outside the line of travel of the magnets. By this mode of construction the whole of the conductor (except a small portion at the ends of the coils outside the line of the field, and therefore useless for inductive purposes) is placed in a strong and uniform field of force. The armature is built in sections, and so arranged that each coil and its section of laminated iron core can be withdrawn from the machine without touching the bearings or the field magnets. The moving parts of the machine are the field magnets, which are wound on laminated iron cores. The grooved pulleys are supported by outside bearings. The bearings are all long, and have large surfaces, and are, moreover, provided with water jackets and water fittings.



View of Engine-house, Monmouth Electricity Works.

The exciters are continuous-current shunt-wound machines with Gramme armature, and are driven by ropes from the alternator shaft. The exciting current of the alternators at full load is about 18 amperes at a pressure of 100 volts.

The switchboard, upon which all the electrical connections converge, is fixed at the end of the engine-house. It is fitted with a very complete set of instruments for controlling the current and regulating its distribution between the several circuits, and is well adapted for easy extension of the generating plant. It is designed to maintain high insulation. A special feature of the arrangement is found in the main switches. These are made in the shape of four metal plugs attached to a massive block of insulating material having a handle at the back. The plugs fit into porcelain sockets containing brass tubes, which are connected to the mains. A long break is made on both poles of the circuit by drawing out the plug, and forms a very efficient double-pole switch. The switchboard is arranged so that the whole of the alternators can be run in parallel or divided into two sections, the division being effected by means of a coupling switch. A hospital shunt is also fitted so that in case of emergency any circuit can be run from any dynamo quite separate from the omnibus bars.

A separate building is reserved for the day-load plant, supplied by Messrs. John Fowler and Co., and consists of

Digitized by Google

a semi-portable under-type engine and boiler combined. The speed of the engine is 135 revolutions per minute, with the boiler working at a pressure of 140lb. per square inch. The room also contains a small feed-water heater and a donkey pump, with the necessary steam and exhaust piping. The engine drives a Hall's combined alternator and exciter, fixed on one bed-plate. A separate switch-board, complete with the necessary instruments, is provided. This is connected to the main switchboard, and is arranged so that the dynamo can be controlled at either board.

The distribution of the electricity is effected by a network of low-tension armoured cables laid direct into the ground, this network being fed by the high-tension mains at transformer-boxes constructed underground at distances of about 200 yards apart. The high-tension cables are of the vulcanised indiarubber class, and are drawn into cast-iron culverts and boxes laid chiefly under the pavements. The surface boxes are in all cases placed at the corners of the roads, and in long, straight runs they are stationed at intervals of not more than 80 to 100 yards apart. These boxes are made in two parts, the bottom part being permanent, and the upper, with the cover, being adjustable, so that its surface may be raised or lowered as the road-level may vary. The lid is filled in with wood, macadam, or pavement according to the construction of the road. The transformers are of the well-known Lowrie-Hall pattern, made by Messrs. John Fowler and Co. In the interior of each box, in addition to the transformer, are placed high and low pressure fuses, a Cardew earthing device, and high and low pressure switches. These last are double-pole and double-break, connected together by an insulated distance piece, so that both switches are turned off at the same moment, which arrangement prevents any sparking, however heavy a load may be switched off.

The rate of charge permitted by the provisional order is 8d. per unit, but the Corporation have fixed upon the following scale of charges: Up to 1,000 units per quarter, 6d. per unit; from 1,000 to 2,000 units per quarter, 5½d.; above 2,000 units per quarter, 5d. The minimum charge to any consumer is 13s. 4d. per quarter. A cash discount of 5 per cent. is allowed on accounts paid within one month. The consumer is at liberty to use his own meter, provided that it complies with the conditions laid down in the provisional order.

Mr. Hammond has been very ably seconded by Mr. R. H. Haynes, the borough engineer, and both these gentlemen have given a considerable amount of personal supervision to the progress of the work of erecting the machinery. Mr. C. D. Copland has been the resident superintendent on behalf of the consulting engineer. The architectural treatment of the buildings was entrusted to Mr. W. Conyers Kirby.

THE ROSS-HEPWORTH ARC LAMP.

This hand-feed lamp, which has been on view at the Tunbridge Wells Exhibition, is intended solely for projection purposes for lanterns, and is designed so that it can be readily attached in the place of limelight apparatus. The inventor claims that it has advantages over the automatic-feed lamps, on the score of simplicity and weight, also being less difficult to keep in order.

The lamp, as will be seen from the illustrations, consists essentially of two carbon-holders supported by guide rods, which are actuated by a pinion working between them and causing them to move in opposite directions. The pinion is connected with a tangent wheel, which engages with a worm-wheel, so that by means of a handle connected with the latter, and projecting from the back of the lamp, a slow feeding motion is imparted to both carbons at once. This feeding handle also performs another very important function in quickly bringing the carbons together in order to strike the arc; this is accomplished by merely pushing the feeding handle forward; the worm-wheel for the moment acts the part of a rack, and imparts a rapid rotary motion to the pinion, which in turn, acting upon the guide rods, brings the carbons together. A spiral spring on the feeding handle serves to instantaneously separate the carbons again, and bring them to the exact position before occupied. This quick-striking mechanism is peculiar to this lamp, and is a most important feature, as it enables the operator to set the carbons to the right distance before lighting up, and after a break in a performance it permits of immediately starting again with the carbons exactly in the same relative position as before. It also permits of the light being rapidly re-established should it from any cause become extinguished. The upper carbon-holder, which is of peculiar construction, is fitted with a milled head, by means of which

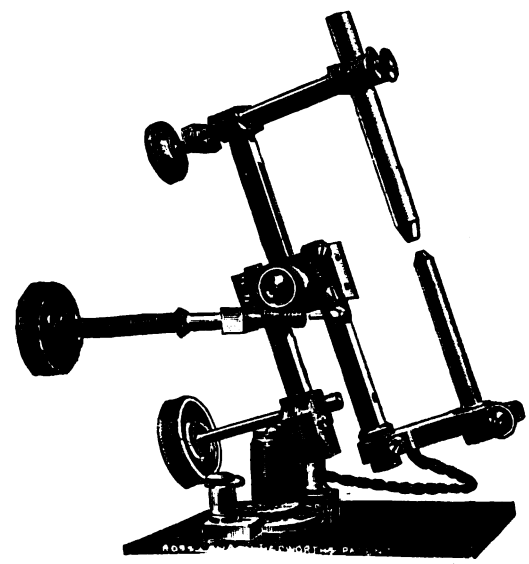


FIG. 1.

the backward displacement of the positive carbon may be adjusted with the greatest nicety, even, if necessary, while the lamp is burning. This adjustment is important, for upon its precision depends the clearness and uniformity of the disc of light upon the screen, and the ability to slightly regulate this during a performance is a valuable boon. The lamp is fitted with a vertical rack and-pinion motion for bringing the point of light into the optical centre, and for keeping it there, should any irregularity in the rate of burning of the two carbons cause a slight displacement.

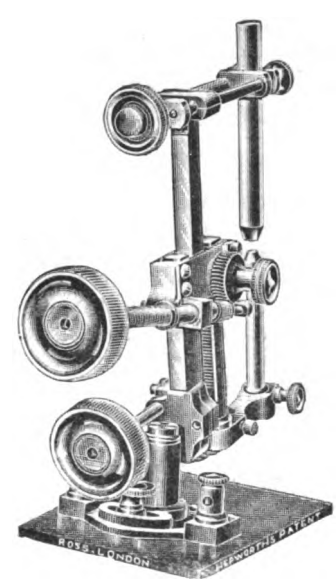

FIG. 2.

The lamp is made to take carbons of 13mm. and 10mm. diameters respectively, suitable for use with a current of from 10 to 15 amperes. When, however, it is desired to employ less current, brass adapting collars are fitted into the carbon-holders so that smaller carbons may be used.

The advantages claimed for this apparatus are an improved slow feeding movement ensuring perfect steadiness of the light; a quick arc striking movement; a fine adjustment for the backward displacement of the positive carbon; a rapid movement for separating the carbon-holders when

Digitized by Google

retrimming, etc. The apparatus is manufactured by Messrs. Ross and Co., of New Bond-street.

THE MANUFACTURE OF THE INCANDESCENT LAMP IN ENGLAND.

It is interesting to find that the Sunbeam Lamp Company, Limited, of Gateshead, do not appear to have been in any way discouraged by the injunction brought against them some two years ago by the Edison and Swan Company; for instead of spending money in demonstrating that their lamp was not an infringement, and so disclosing their process, they spent the time profitably in laying down plant, procuring additional premises, and fitting them throughout for the special purpose of incandescent lamp manufacture. The name of the Sunbeam Lamp Company has in the past been associated with lamps of high candle-power, ranging from 150 c.p. upwards, but the plant laid down has been specially designed not only for the manufacture of the larger lamps, but for the output of the smaller lamps from 5 c.p. The manufacture of all stages is personally under the supervision of the managing director, Mr. J. W. Edmundson, who has been connected with the manufacture from its first conception, and was the first to perfect high candle-power lamps, so that no one at present engaged in the manufacture of incandescent electric lamps has had a better practical experience of actual manufacture than Mr. Edmundson, and no firm have greater facilities for perfect manufacture than the company he at present manages.

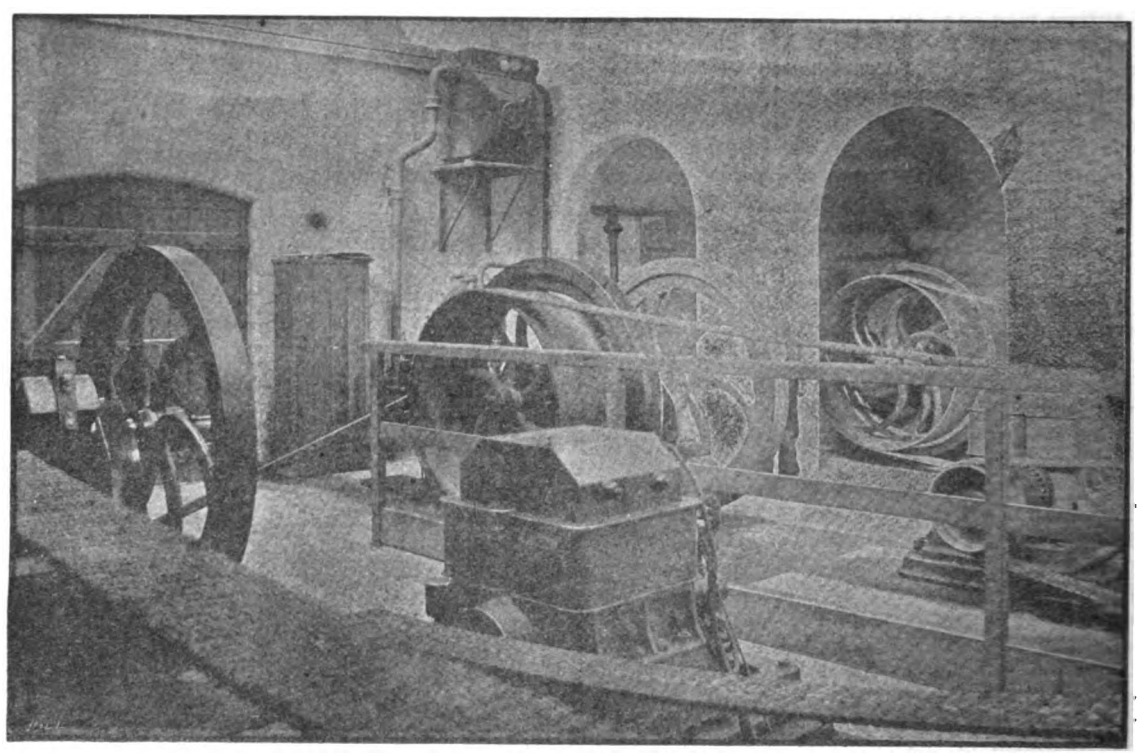

FIG. 1.

The building in which the works are situated is of both historic and romantic interest, it being made, under the name of "Gateshead Hall," the scene of the opening chapter of Charlotte Brontë's novel, "Jane Eyre." When the unfortunate fire of 1891 burnt out the interior of this building—that had stood 150 years—the company rearranged its workrooms in the most satisfactory manner. The current is supplied by four large dynamos of the Clarke-Chapman type, driven by three Otto gas-engines of 20 h.p. and 16 h.p. Fig. 1 shows the interior of the engine-room.

The main building (Fig. 2) is a three-storeyed block and has extensive cellar accommodation, which is wisely used by the company as a store-house for bulbs. The general and secretary's offices with Board-room are situated on the ground floor, where are also the packing-room, despatch office, blowroom, and exhausting department. In describing the works we shall endeavour to follow, as far as possible, the manufacture of one of these lamps. Very little information can be obtained as to the manufacture of the carbon, which the company, in their own interests, do not care to divulge. After the carbons are moulded to different sizes as may be required, they are then carefully packed in crucibles and carried to a furnace for carbonising. The filament is now taken to the depositing-room (Fig. 3), which is a branch from the main building and entirely fireproof, where it is electrically united to the platinum stems. From here we follow the filament to the treating-room, situated on the first floor, where each filament is tested separately for resistance and subjected to the process of flashing in hydro-carbon gas in order to obtain equality in the different filaments. For the next process we descend to the ground floor, where the filaments are being sealed into the glass bulbs by men and boys, no girls being employed in this operation. It is especially interesting to watch this operation with the high candle-power filaments, which can only be treated by very experienced glass-blowers, of whom this company appear to have been especially fortunate in their choice. We next are taken to the exhausting department, Fig. 4, where the lamps are sealed to a vacuum pump, and the air in the bulb extracted by means of a special system of Sprengel pumps. The experienced hand only knows when the lamp is ready for sealing off, but before doing so a very heavy current is passed through the lamps to drive out any gases that may still remain. This is a severe test, but the comparatively few lamps returned from this department speaks for itself as to the excellency of the filament. After the operation of exhausting is completed, the lamps are then handed to the testing department, where each lamp is separately tested by a Bunsen photometer. Most careful tests are made of candle-power, voltage, and efficiency, and no lamp is passed that is not equal to the standard. The lamps are thus assorted, and in order to prevent any possibility of error a few of each kind are taken and again tested on a special photometer. From here the lamps are taken to the collaring department, where they are fitted with brass caps according to requirements of various orders. From this department we are next introduced to the mounting-room, where the voltage, candle-power, and the name "Sunbeam" are marked by a special patent process on every lamp. Here also the lamps are carefully tested to ascertain that the connections are in order, and that the vacuum is perfect. The lamps are then washed and papered and sent finally to the storeroom.

The Sunbeam Lamp Company have a special brass collar,

Digitized by Google

which is preferred by many consumers. This collar is in the form of a claw, which springs on to the top of the lamp and holds it quite firmly, and so allows a passage of air all round the lamp, keeping the latter cool, and obviating the trouble of loose collars. For those who prefer the ordinary plaster-capped lamps, the company have prepared a cement specially manufactured for the capping purpose.

In other departments the wires for supporting the carbons are being made for both large and small lamps, and similar operations as already enumerated for the small lamps are in force for the lamps of large candle-power. The company confine itself almost solely to the production of the lamps, but have patented a special holder for large incandescent lamps, and in another room these are being made of various sizes and patterns.

It is pleasing to find that the efforts of the Sunbeam Lamp Company, Limited, to manufacture a first-class English-made lamp are being rewarded. They have been compelled to increase their facilities of output, and only last month completed large extensions of plant in their endeavours to meet the ever-increasing demand for the Sunbeam lamp, which, notwithstanding the cheapness of the foreign-made article, keeps its hold on the market.

Liverpool Engineering Society.—The opening meeting of the twenty-second session of this society will be held on the evening of Wednesday, the 30th inst., at 8 o'clock, when the president-elect, Mr. Arthur J. Maginnis, M.I.N.A., will deliver his inaugural address. On February 5, 1896, Mr. W. G. P. Macmuldrow will read a paper on "Some Instruments Used for Measuring and Recording Electrical Energy"; on February 19 Mr. Alexander Ross, M.I.C.E. (past-president), will give one on "Light Railways"; and on April 1 Mr. Sherrard Cowper-Coles will discourse on "Electro-Zincing."

BOUND VOLUMES.

Vol. XV. of new series of "THE ELECTRICAL ENGINEER" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

MUNICIPAL ENTERPRISE.

It is well now and again to look at the possibilities of the future as indicated by the certainties of the past. October is the month during which municipal affairs are subjected to a somewhat fierce light—for it is the month of candidates and elections. A careful examination of addresses and speeches will show that year by year there is a growing interest in electrical work. Of course, the many central stations opened and in progress show this interest; but besides these actualities, it is indeed suggestive of increasing interest to find the many references to electrical matters, for and against, to induce the electors to vote for particular candidates. At this stage of the world's history it is difficult to account for the hostility of ratepayers to the municipalities or districts embarking in electric light undertakings, except from the one view that the hostile citizens do not really understand the question. Thus it is reported that a large representative meeting of ratepayers at Wimbledon has declared against electric lighting. It is the duty of all acquainted with the subject to enlighten their fellows as far as possible, and they cannot have better opportunities than during the meetings held in support of candidates for municipal office. The great controlling influences of municipal life are two—first, that relating to the health of the community; secondly, that relating to the general comfort of the community. Under the first of these comes the question of sanitation, the supply of pure water and air; under the second, the proper maintenance of roads and streets, and the proper generation and distribution of artificial light. The commercial instinct of the nation is such that as regards water and light supply the question is often put upon the footing of pounds, shillings, and pence—that is, will it pay? In both cases the answer is and must be in the affirmative. The householders must have water and artificial light, and in these days of advanced civilisation these cannot be obtained without payment. The consideration then resolves itself into the question whether it is better for the ratepayers to co-operate and obtain what they must have in the best form at the lowest price, or take what is provided by capitalists whose object is to secure a good return for the capital advanced. There is no single instance—indeed, such an example is impossible—wherein outsiders can do better than municipalities. Of course, we assume everything in both cases is done with strict regard to integrity. As we have often pointed out before, a municipality can obtain money at a lower rate than a company, and its expenses ought never to be so heavy as those of a company. Both must keep their stations in the highest state of efficiency, but the company has besides to pay dividends, capital remaining constant, while the municipality pays off its capital, and at the end of a term of years has its property with no capital charge outstanding. It cannot for a moment be maintained that under a municipality the consumers pay more for the same supply; hence from whatever point of view the question be considered it will have to be conceded that

Digitized by Google

the municipal control is better than that of a company. The hostility of ratepayers is unaccountable from another point of view. Under ordinary conditions—even with a comparatively small demand—the electric light station is no drag upon the rates, and, so far as we can ascertain, soon ceases to require pecuniary aid. There is one point in connection with the capital question we have never yet seen fully considered. Assume that the capital borrowed has to be paid within thirty years. At the end of that period the capital account vanishes; but it may be that the rate of paying off is too fast, and a portion of such payment has fallen upon the rates. This means that the rates have advanced a certain part of the capital, which is repaid after thirty years by the revenue then coming in aid of the rates. The above assumption is unlikely, for it seems pretty certain that every one of the central stations erected will with good management soon earn enough to keep the machinery efficient and to pay the annual return of capital, in most cases leaving something over in aid of the rates. We had intended to direct attention to various parts of Prof. Fleming's report to the Plymouth Council, but our readers will be able to see his points themselves, and we would urge those in a position to do so to take an active part in spreading abroad the true facts concerning electrical development during the forthcoming municipal elections.

OBITUARY.

THE LATE FRANKLIN L. POPE.

We regret to have to record the death of Frank Pope, who met with a fatal accident on Sunday, October 13, being killed in his own house by a shock of 3,000 volts. The late Frank Pope had endeared himself to many members of the profession on this side, and, as might be expected, to a far larger number on the other side. The time has not yet come—and will not for many years, if ever, come—when the writer can divulge a certain historic incident in which his late friend played a most prominent part. The incident carried alarm and dismay to certain patentees and financiers across the Atlantic, and rendered for ever impossible any harmonious working between these people and the writer. Frank Pope was better known, perhaps, in the telegraphic and telephonic world than in the electric light world, but his innate and versatile talent kept him fairly abreast of recent developments, and his writings show how keenly alive he was to the possibilities of electrical development. His memory will long be dear to the many with whom he lived and worked.

THE BRISTOL, ST. GEORGE, AND KINGSWOOD ELECTRIC TRAMWAYS.

This new line was opened on Monday last in the presence of a large and representative gathering of engineers. The history of the tramway company owning this line shows a steady advance, and we trust that the financial success of this new branch will be in keeping with advantages gained by the adoption of electric traction. The configuration of the roads in and round Bristol is such as to render horse traction cruelty to animals. Thus, in the line to Kingswood the maximum grade is 1 in 15, and this lasts for a distance of 220 yards, and there are several long slopes of 1 in 30, 1 in 35, etc.

The first step taken to bring about the Kingswood extension was in 1891, when a provisional order for carrying out the work was obtained; but it was not until the modified regulations recommended by the Joint Committee of both Houses of Parliament to operate electric traction were known that the Bristol directors felt justified in entering upon the project. At this stage, Mr. J. Clifton Robinson, C.E., who was the first general manager of the Bristol company, and who had subsequently acquired great experience of electric traction in America, was called in by the directors and asked to report fully on the whole subject, and particularly to formulate a scheme for an electric line to Kingswood. That gentleman's report was of such an encouraging nature that the directors accepted his recommendations, and instructed their engineer, Mr. Joseph Kincaid, M.I.C.E., to carry out the works, which he has done most successfully. The necessary powers to enable the company to proceed with their scheme of electric traction for Bristol in relation to the Kingswood Electric Tramway were obtained in 1894. The contract for the work was placed with the British Thomson-Houston Company, whose engineer, Mr. R. Blackwell, has had full charge of the equipment, Mr. Philip Dawson being his local representative.

The track to Kingswood has been entirely relaid with steel rails weighing 76lb. per yard. The copper bonds connecting adjoining rails are of the Chicago pattern, as described in our issue of September 20. This line is the first to be laid to comply with the new Board of Trade regulations concerning overhead wires and earthed returns. The requirements of these regulations were as follow: (*a*) the difference of potential between any two points on the earth return shall not exceed seven volts; (*b*) the leakage to earth from the feeders and trolley wire, etc., shall not exceed $\frac{1}{100}$ of an ampere per mile of tramway. In the most severe test to which this line has been subject the Board of Trade limits were never approached, which shows that with good attention to detail the restrictions are not prohibitive. The trolley wires are supported on standards made of steel tubes, placed mostly on the kerb of the footpath on one side of the road. A long ornamental bracket carries the insulators for the two trolley wires. In other places, where there is more width, the poles are placed in the centre of the road, and two brackets on either side are used. In Old Market-street the alternate posts are used as arc lamp-pillars. The Dickinson trolley system has been adopted, and this greatly facilitates the line construction. The power-house is equipped with two Adamson boilers, fed by Vicars stokers. The whole of the auxiliary power for driving these and the feed pumps is obtained from electric motors. Duplicate steam-pipes are used to supply three Willans engines of the H H S size, which develops some 135 i.h.p. each at a speed of 380 revolutions. These drive, by rope gearing, three Thomson-Houston four-pole dynamos, whose individual output is 200 amperes at 550 volts at a speed of 650 revolutions.

The large proportion of the work has been executed in America, and while in no way detracting from the excellence of the results, we hope that future traction work in this country will be kept more in the hands of English firms.

The opening ceremony on Monday was commenced in Old Market-street, from whence the guests were conveyed in eight cars to the Kingswood end of the line. When the guests had taken their seats, they were each presented with a beautifully illustrated description of the tramway. For more than an hour before twelve o'clock, the hour at which the procession of cars was to start, people began to gather in thousands in Old Market-street, and as noon approached the crowd became more and more dense, until the street was thick from end to end with interested spectators. The journey to Kingswood took about half an hour, and when the whole of the cars had reached that end of the line Mr. W. Butler, the chairman of the company, declared the line open. On the way back a halt was made to enable the power station to be inspected.

The guests were afterwards entertained by the tramway company at the Grand Hotel, when, after a well-served luncheon, the usual congratulatory toasts were discussed.

This line should do much to dispel the objections to the overhead system of traction, as the line equipment is an ornament to the thoroughfare.

ABDANK'S HYSTERESIS COMPENSATOR.*

The researches of Ewing, Hopkinson, and others have shown how greatly the action of iron depends upon its previous magnetic history, and hence when iron masses are employed in electrical indicating and other apparatus these effects of residual magnetism, coming under the more general class of hysteresis phenomena, introduce errors. As a result, indicating instruments of this type have been shunned in the past where accuracy was considered desirable. The simplicity and cheapness of this type of instruments have nevertheless given them considerable vogue, and the most recent attempt to remove the cause of objection to their use will therefore be of interest.

M. B. Abdank-Abakanowicz, of Paris, has just devised what he calls a hysteresis compensator, to effect the desired purpose. This he accomplishes by combining with a magnetic circuit one or more masses of iron or steel, constituting

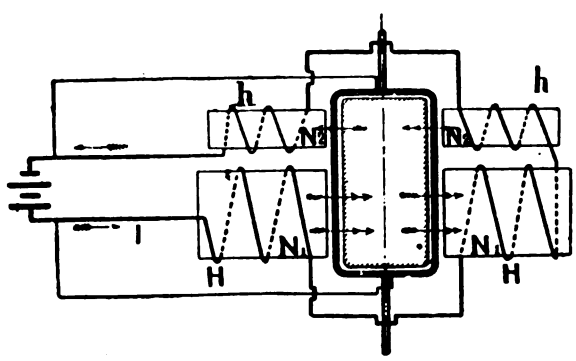

FIG. 1.

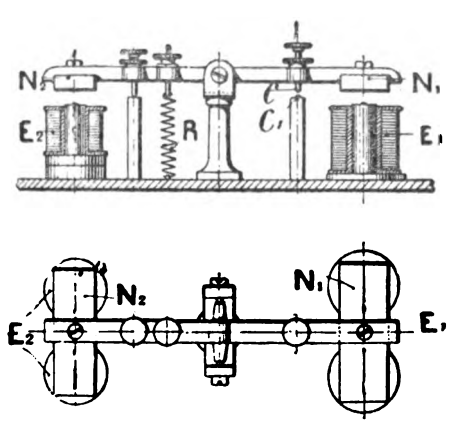
what he calls a "secondary differential magnetic circuit," the action of the lines of force of the secondary circuit being opposed to those of the principal circuit. By properly choosing the dimensions of the secondary, with reference to those of the principal magnetic circuit, a differential value may be obtained for all currents within the range of the apparatus which will be proportional to those currents. In other words, the effect of the residual magnetism of the first circuit is neutralised by the residual magnetism of the second.

The accompanying diagram (Fig. 1) shows the application of these principles to a continuous-current wattmeter. The potential is measured by the movable coil, and the current is made to traverse the coils, H, of the principal electromagnet, and the coils, *h*, of the secondary or compensating electromagnet. The core N′, which produces the principal flux, is made of metal having the smallest amount of hysteresis possible, of soft iron, for instance, while N^2, which produces the flux for compensation, is made of cast iron or steel, or



FIGS. 2 AND 3.

some metal having a high coefficient of hysteresis. The double arrows in the diagram represent the directions of the magnetic fluxes, and the single arrows those of the current. By varying the sections of the two cores, N′ N^2, the ampere-turns applied to these cores and the air-spaces of the magnetic circuits, it is possible to make a combination such that the residual magnetism is either entirely or only in part compensated, and that the resultant magnetic flux will be always proportional to the current, in which case the resultant torque of the armature will be proportional to the watts. Practically the same method may be applied to the case of a solenoid acting on a core of soft iron, which core it is desired shall be drawn in by the action of the solenoid to a certain predetermined point when the current shall have attained a certain predetermined value.

Figs. 2 and 3 show the same principle applied to a relay. The principal electromagnet, E′, acts on the soft iron armature, N′, in opposition to the spring, R, and against the action of the differential electromagnet, E^2, and the armature, N^2, which have a high coefficient of hysteresis. The two electromagnets are supposed to be excited by the same current. By choosing suitably the elements of the magnetic circuits of the two electromagnets it is easy to arrive at such a combination as will ensure that the contact between *c c′* will always just take place when the current has attained a certain predetermined value, whatever may have been the previous values of the current. The practical rule to follow in this case is as follows: The attraction due to the residual magnetism of the electromagnet E^2 and of the armature N^2, ought to be equal to the attraction produced by the residual magnetism of the electromagnet E′ and of the armature N′ for the position of contact.

* From the *Electrical Engineer* (New York).

THE JEANTEAUD ELECTRIC CARRIAGE.

Considerable attention is just now being devoted both in France and this country to the question of electric carriages for road work. The convenience of an electric carriage is obvious; its most serious defect is the necessity of returning to the charging station to exchange or recharge the accumulators after a certain distance has been run. The first question then to be determined in constructing an electric carriage is the distance to be run without

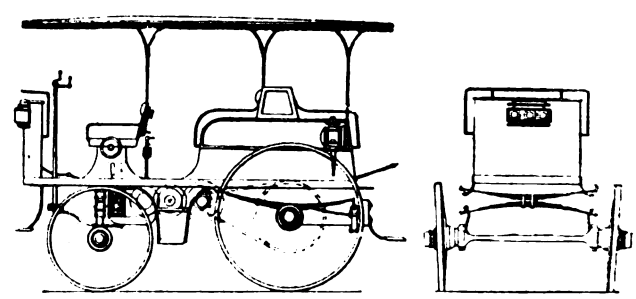


FIG. 1.

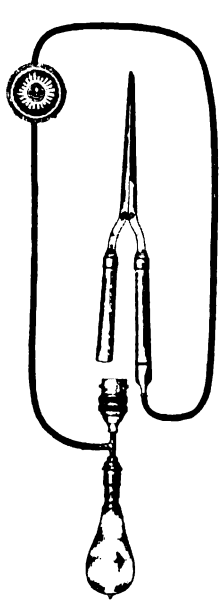
recharging and the speed desired. Mr. C. W. Rechniewski, writing in *L'Electricien* of October 3 on the subject of Mr. Jeanteaud's carriage, which recently did the journey from Paris to Bordeaux, says the Fulmen accumulators have hitherto given the best results in this kind of work. The batteries used for the Paris to Bordeaux run weighed 850 kilogrammes complete (between 16cwt. and 17cwt.) and were made up of 38 cells, contained in 12 boxes of three or four cells each. The electrodes of each cell weigh 33lb. and have a capacity of 300 ampere-hours under the ordinary conditions of a discharge spread over 10 hours. At the rate of discharge of 70 amperes, or 2·1 amperes per pound of plate, the capacity of the battery was still 210 ampere-hours. Unfortunately, the adoption of 10 hours as the time of discharge would place a very low limit on the rate of speed. The best speed record for electric carriages belongs at present to Mr. Jeanteaud, who in designing his carriage has departed from the ordinary lines of carriage-building, so that the eye should not at once be struck by the absence of the horses. The carriage (Fig. 1) has two cross seats, each holding two persons, and a third seat at the back, also for two persons. There is a dashboard in front carrying an electric lamp. The accumulators are placed under the hind seats. The wheels are hickory, and are respectively 39½in. and 55in. in diameter. The total weight of the loaded carriage is about 3 tons 3cwt., and is distributed so that the front wheels support 23½cwt. and the rear wheels 39½cwt. Each of the front wheels is independently

Digitized by Google

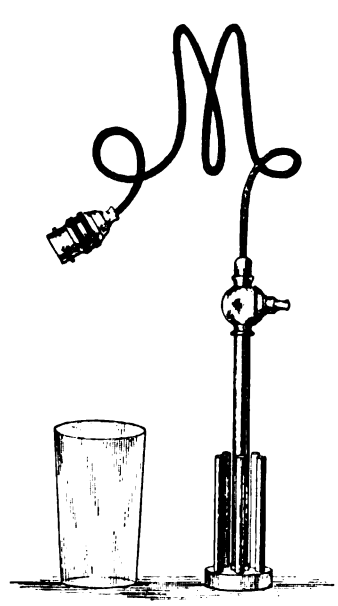
pivoted for steering purposes, which is stated to give great advantages over other methods of steering. Two transverse springs on the fixed axle carry the body of the carriage. The frame is of steel throughout. An accident at starting from Paris bent the rear axle, causing the bearing to heat, and hence necessitating frequent stops for cooling and lubrication. For stopping there is provided a strong brake acting on the naves, and an auxiliary brake worked from either side of the front seat. The wheels are driven by two chains, from a spindle carrying the differential speed gear, giving speeds of from 7 to 15 miles per hour. The change of speed was to have been done by a Bovet magnetic gear, but this not being ready in time ordinary spur gear was substituted. The motor was constructed by the Société Postel Vinay, and has an efficiency exceeding 90 per cent., and at its normal rate is intended to give 7 h.p. at 70 volts. The weight of the motor is about 4½cwt., and it can be made to develop 14 h.p. or 15 h.p. when mounting inclines. For the Paris-Bordeaux run it was arranged that only the steering should be done by the conductor, the driving apparatus being managed from the second seat. This includes reversing gear and switches for the accumulators, and for separately exciting the field magnets, so as to maintain the same speed down hill as on the level. This was found exceedingly useful, the motor acting as a brake, and under certain circumstances delivering back a current of 80 amperes to the accumulators. Practically, however, the amount of the current so restored was not worth taking into account, but the regulation of the speed down hill was perfect. On the other hand, at slow speeds only portions of the accumulators were worked. A fresh set of accumulator cells, weighing 16½cwt., was required after about 25 to 44 miles traversed, according to the gradients. For charging the accumulators a stoppage of 10 minutes was required, the connections being made automatically by springs and plates. The construction of the vehicle was only begun three months before the Paris-Bordeaux competition, and it is stated that the object of Messrs. Jeanteaud and Brault, the designers, was not so much to gain the prize offered as to show that electric road carriages were already a practical success. Mr. C. W. Rechniewski considers that this was fully realised.

HOUSEHOLD ELECTRICITY.

Some years ago it was customary for popular writers to portray the many uses to which electricity might be put. By its aid we were to clean our boots, brush our hats, and, in fact,



Electric Curling-Tongs.

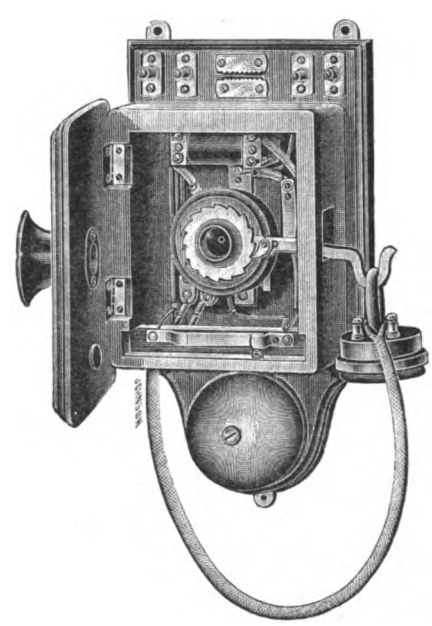


Electric Heater.

carry on all manner of household business. Many of the suggestions then made are in a fair way of being realised, and the more of these handy little household utensils are put upon the market the better it will be for electricity. One of the dreaded pests in a house is that portable hair-curling apparatus which burns methylated spirits. Now, whatever house contains electric lamps can be fitted with less dangerous and more cleanly apparatus of the kind. We herewith illustrate the curling-tongs patented by Mr. March, and which to the eyes of the sterner sex seem far more cleanly and far better adapted for their work than the old fashioned tongues. They can be attached to any lamp-holder. The temperature can be kept uniform as long as required. There is no waiting for the tongues to be heated so that the toilet operations can be carried on without delay. Another apparatus introduced by Mr. March is a small electric heater designed to be put into the fluid to be heated, so that there is no waste of heat. The apparatus is silver-plated and easily cleaned, so that objections on the part of uncleanliness can hardly be made. So far as we have seen, both these pieces of apparatus are admirably adapted for the purpose for which they are to be used. The heater is small enough to go into an ordinary tumbler. The illustration explains itself.

GENT'S AUTOMATIC REVOLVING TELEPHONE TRANSMITTER.

In transmitters of the granulated carbon or Hunnings variety, the carbon is apt to cake or wedge at the bottom, and speaking is thereby much impaired. To overcome this, instruments with revolving transmitters were some time ago put on the market, the purpose being that by giving a half-turn or so to the mouthpiece, which was fixed to the microphone or transmitter case, the carbon might be shaken up and speaking rendered clearer. That this is a necessity is proved by the fact that the Hunnings instruments adopted by the Post Office are so fitted.



Even if one always thought of it, it is somewhat troublesome to have to give the mouthpiece a turn before speaking; and to obviate this, Messrs. Gent and Co., of Faraday Works, Leicester, have brought out an instrument in which the transmitter is automatically revolved. The arrangement is shown in the figure, and it will be clear that the microphone case is moved round a little every time the receiver is taken off its hook. In another form, this automatic rotation is performed not by the switch-hook, but by the ringing key. W. Perren Maycock.

Harrogate.—The Electric Lighting Committee have accepted the following tenders: Lancashire boilers, economiser, feed pumps, and accessories, Holdsworth and Sons, Leeds-road, Bradford, £1,516 (without brickwork settings, etc.); steam alternators, condensers, fittings, etc., steam, exhaust, feed, and sundry pipes, valves, etc., Ferranti, Limited, Charterhouse-square, E.C. £7,428 (125-unit plants in place of 100-unit plants); switchboards and instruments, Ferranti, Limited, £671. 3s; high and low-tension mains, British Insulated Wire Company, Prescot, £2,931. 1s. 6d.; transformers and accessories, Brush Company, Queen Victoria-street, E.C., £403. 7s.; overhead travelling cranes, Southgate Engineering Company, Fenchurch-street, E.C., £190. There were in all 57 tenders received.

THE GIANT'S CAUSEWAY ELECTRIC RAILWAY.

The following statement has been forwarded to the Board of Trade, on behalf of the Giant's Causeway Electric and Tramway Company, by Mr. A. Traill, chairman of the company :

The directors wish in the first instance to remind the Board of Trade that this has been the pioneer of electric railways, being the first constructed for commercial purposes in any part of the world. It is scarcely, therefore, to be expected that it should have escaped the misfortunes, experimental or other, which necessarily accompany the early stages of a new invention. Both the Board of Trade and this company have been to a great extent groping in the dark for a number of years, and the responsibility for any mishaps which may have occurred to animals must be shared by both, and the company are quite as anxious as the Board can be to devise any further arrangements as may be proved necessary for the greater security of life and property. The directors, however, hope that the Board will not yield so far to unreasoning panic as to involve the company in unbearable expense. The directors are prepared to admit, as the result of the evidence at the recent enquiry, that a current of low pressure of 250 to 300 volts can no longer be considered safe for the lower animals, but they are equally satisfied as the result of constant experience for more than 12 years that such a current by mere contact is not dangerous to human life. Overwhelming evidence to that effect was produced at the recent enquiry. While it is admitted that animals were killed by the electric current, generally from long contact with the rail, the directors cannot admit that the young man Walne was so killed, and they ascribe his death to the fall from the bicycle, in the absence of any *post-mortem* examination from which the actual cause of death could be ascertained. Even in regard to animals, it is remarkable, after all, how few cases of death have occurred—nine in 12 years, though when brought forward together the array looked formidable. It should be remembered that there have been hundreds of cases of contact which have not proved fatal, even to animals. It is remarkable that the fatal cases have all occurred in wet weather. A current, which on a dry day is almost imperceptible, seems suddenly to become dangerous to animals, when everything is soaked in wet. It is, however, also remarkable that in all these cases of death of animals there was contributory negligence by the owners. The directors thought it to be a wise and just policy, though not legally liable for damages, to pay liberal compensation to persons whose animals were injured, even though they had contributed by their negligence to the result, but they never hesitated to resist extortionate claims.

In relation to the recent loss of life by Mr. Walne, the bicyclist, the directors wish to call the particular attention of the Board of Trade to the evidence produced on behalf of the company. It was shown that drunken persons had been repeatedly in contact with the rail for considerable periods and in all weathers, without any injurious effects ; that workmen employed on the line and about the rail were constantly touching the rail, one man in particular (Boyd) having been for 15 minutes in a cramped position effecting repairs under a car, with his head and neck touching the rail, and a current passing through him for all that time ; that hundreds of persons, tourists and others, were constantly taking electric shocks, from curiosity or for amusement, while some used the current for medicinal or surgical purposes. With this evidence constantly before them, it was impossible for the directors to come to the conclusion that any danger could arise to human life, but none could expect them to have made provision against the extraordinary case of a young man riding rapidly along the public road, suddenly turning his bicycle against the raised kerbstone of the footpath in order to get up on that path, then turning a somersault through the air over the head of his bicycle for a distance over 6ft., lighting with his head against the fence and his arms beyond the rail, and his chest against it. A stone wall in a similar position would be quite as dangerous to a bicyclist getting a similar fall, and yet the road authorities are not expected to make provision for the safety of the public against such accidents. Bicyclists are being constantly killed by falls not as severe as this one, and yet it seems to be assumed by many that it was not this fall that killed him, but the shock from the electric current. In proof of this much stress was laid upon the fact that there were superficial burns upon Mr. Walne's chest. It is quite natural in the present state of knowledge, or rather want of knowledge, of the nature of death by electricity that persons who are totally ignorant of such matters should jump at once to so easy and natural a conclusion ; but the Board of Trade will know that in all cases of shocks from electricity which have been recorded the person, if not killed at once, gradually got better till he recovered from the effect of the shock, while in the case of Mr. Walne it was distinctly proved that he was not killed on the spot, that he was able to swallow brandy, and knew what he was then doing, and that instead of gradually coming out of the shock, he got worse and worse until he died, about half an hour afterwards. This points more clearly to some lesion of the brain or heart arising from the fall, than to death from an electric shock. With regard to the burns on his chest, they were quite superficial, and of small extent ; a florin would have covered the only one of any size. A spark passing from his soaking wet clothes to the skin, on his making and breaking the contact, while struggling on the rail, would have caused these burns, and it was proved at the enquiry that a girl in contact with the current got her hands severely burned from a like cause, without any fatal or serious results.

The directors wish to point out that the verdict of the jury at the coroner's inquest states, in accordance with the evidence of the doctors, that the young man died of shock, but the words "electric shock" were carefuly excluded. The shock was twofold, from the fall and from the electric current. That from the current alone would certainly not have killed him, because at that hour, with only one car on the line, the pressure of the current was necessarily low. The shock from the fall might or might not alone have killed him, but it is remarkable that the blow which he received on the chest on striking the rail was proved to have been exactly on that spot, the ensiform cartilage, which is known to be dangerous, the very spot where it is on record that a man has received a fatal blow at a prize fight. In the absence of a *post-mortem* examination it appears to be a reasonable inference that however the electric current may have been accessory or otherwise towards the prevention of his recovery from shock caused by the fall, it was the fall from the bicycle which was the primary cause of death. Since the enquiry a case has come to the knowledge of the directors of a similar accident to a bicyclist, who can be produced, who was thrown on the electric rail without receiving any serious injury.

In conclusion, the directors wish to call the attention of the Board of Trade to the strong claim the company have on the sympathy of the general public in their great undertaking, and the interests of 100,000 travellers yearly to the Causeway must be taken into consideration, as well as those of a few local owners of cattle. Anyone who remembers this district 13 years ago will know that the Giant's Causeway, though well known by repute all over the world, was visited by but few, and those mostly tourists. It was but little known to the mass of people, the working classes of this country. Five thousand visitors in the year would be an over-estimate for the years before 1883. In that, their first year, this company carried some 54,000 persons. That number has gradually and steadily increased year by year, until in 1894 it reached the large number of 93,000, and this year the number will almost certainly exceed 100,000. A rare boon has been opened up for the working classes of the North of Ireland. A man can leave Belfast by early train for Portrush, travel over this line, get four or five hours at the Giant's Causeway, and get home comfortably the same evening for the sum of 3s. 6d., of which this company gets 1s. Simultaneously with this, there has been a great increase in the size and population of Portrush. There has latterly been an annual increase of £400 or £500 a year in the valuation of the town, and with a winter population of 1,600, the summer population comes up to some 6,000 persons. With the addition of one of the finest golf grounds in the United Kingdom, this whole district has become completely opened up, and money has been freely poured into the country. The directors claim that this company has been the pioneer of all this progress.

Owing to the expense of steam, and the smallness of the number of travellers in the winter months, the line has been hitherto worked during that part of the year entirely by electricity, and the directors hope that whatever arrangements the Board of Trade may think it necessary to require for the full working by electricity in the future, they will agree to allow sufficient electricity to be used during the ensuing winter to drive a single car without a trailer. When the voltage for this purpose had been defined, a volt-cut-off at the waterfall will provide against any excess of pressure being used. In addition, the directors will be prepared to make any reasonable compensation, just as they have hitherto done, in the case of any animals accidentally injured, due allowance being made in respect of contributory negligence by the owners.

PLYMOUTH.

The following is the report to the Electric Lighting Committee of the Corporation of Plymouth by Dr. J. A. Fleming, F.R.S. :

In accordance with the request conveyed to me by your town clerk (Mr. Ellis), I have collected together in this report such information and data with regard to municipal electric lighting as will, I trust, enable you to form decisions on the question of the electric lighting of Plymouth, and have to this added my own opinions and the advice I beg to tender you thereon. I was requested to advise (1) on the electric lighting generally of Plymouth by the Corporation ; (2) on the utilisation of town refuse as fuel ; (3) on the employment of electric traction in connection with tramcars in Plymouth.

It may be useful to preface other remarks by a short statement of the present state of electric lighting in the United Kingdom.

PRESENT CONDITION OF ELECTRIC LIGHTING IN THE UNITED KINGDOM.

Leaving out of account London, there are at the present time (1895) some 82 towns in the United Kingdom in which a public electric supply is given, or about to be given, either by the local authority, corporation, or by a limited company. Of these stations 47 have been established by municipal authorities, and 35 by limited companies. Broadly speaking, the electric supply is being given in each place by one or both of two systems—viz., either by the alternating-current system or by continuous-current system. The alternate-current stations are generally called high-tension stations, because the electric current is generated in them at a high pressure (about 2,000 volts), and then reduced down to a low pressure (100 volts) for use in the houses by transformers either placed in the buildings, or in special transformer sub stations. The continuous-current stations are generally called low-tension stations, because in them (with the exception of Oxford and one or two other places), the continuous current is generated at a low pressure (110 or 220 volts) and supplied to the consumers direct without transformation. The capacity of an electric station is popularly estimated by stating the number of 8-c p. incandescent lamps it can supply, or which are connected to it. It is more exactly estimated by starting the safe or effective output capacity of the dynamo plant in kilowatts.

A classified list of the 82 provincial electric supply stations of the United Kingdom is given herewith, divided so as to show: (1) stations established by local authorities on the alternating-current system; (2) stations established by local authorities on the continuous-current system; (3) stations established by companies on the alternating-current system; (4) stations established by companies on the continuous-current system, with the approximate present lamp connection of each place, the price at which the electric energy is sold per Board of Trade unit, and the price of gas in that place. These figures were correct at the end of the year 1894, but progress is so rapid in some towns that they are in many cases already antiquated. They will serve, however, as a general indication of the state of electric lighting in 1894.

It will not be necessary to enter into a detailed technical description of these two principal methods of electric supply. Suffice it to say, that in places where the demand for electric light is concentrated, and where the supply station can be placed in the midst of, or at no great distance from, the centre of the area to be lit, it has been found advantageous to adopt the system of continuous-current supply, with or without the assistance of accumulators. In this system the generating machines send electric current directly into the supply mains, and the consumers draw off their supply directly from these conductors. If the area of supply is large, or the demand scattered, or the supply station can be most conveniently situated at a distance from the area, then it has been found best to adopt the system of alternating-current supply, in which the current is generated at a high pressure of about 2,000 or 2,400 volts, and it is sent to certain sub-stations in which are placed appliances called transformers. These transformers generate from the currents of high pressure, called primary currents, other currents of low pressure at 100 or 110 volts, called secondary currents, and these last are distributed to the houses of users and to the other buildings to be lit. The alternating-current system has the advantage that small detached areas of supply are more easily served, and pioneer work in the outskirts of the main area of supply in a town is easily carried on by means of transformers placed in the houses. Many considerations have to guide the engineer who is called upon to make a recommendation as to system, and, whilst in the generality of cases there can be no little difference of opinion as to the choice to be made, there is in others some difficulty in making the right selection.

The list of municipal electric light undertakings shows, however, that the public supply of electric current is no longer a matter on which the slightest room for doubt as to its practical success can exist. The results of the last five years' experience have also been to show that the advantages to the local authority in retaining the public supply of electricity in its own hands are very great. In many cases in which supply companies have built up a solid business, such as in the towns of Liverpool, Bath, Southampton, and other places, the corporation or local authority are now feeling the necessity for acquiring it, and will generally have to pay more for it than it cost in the first instance to establish it.* It may therefore be remarked that it is advantageous that in Plymouth there is no electric lighting company in present possession, and requiring to be bought out, but a clear field exists for establishing a corporation electric station on the best lines. The experience gained in the last five years or more of the financial results of working shows that the business of public electric supply can be carried on with a profit which is not only sufficient to repay the loan and meet current interest, but which affords a prospect of making a further margin of profit to the advantage of the town. The experience generally has been that the first year of working is sufficient to place the undertaking in a position to pay its outgoing expenses, and that from and after that time increasing contributions are made to the loan repayment and interest fund.

* Since the above paragraph was written, the Corporation of Liverpool have purchased by valuation the plant and business of the Liverpool Electric Lighting Company for £400,000, a sum greatly in excess of the original first cost of the undertaking.

Digitized by Google

System Suggested for Adoption at Plymouth.

After carefully considering the present and probable future requirements of Plymouth in the matter of electric lighting, and viewing the site by the Cattewater suggested for an electric station, I am of opinion that the conditions indicate as most suitable for the district the adoption of an alternating-current supply system with transformer sub-centres. I consider that the Cattewater site, a property owned by the Corporation, is well adapted for the establishment of a Corporation electric supply station on this system. In this position several advantages will be gained. In the first place, there is access for coal delivery both by rail and by water; in the next place, water can be obtained for condensation; and, lastly, the station is removed from the residential portion of the town. If on other grounds it is desirable to establish a refuse destructor, as subsequently discussed, it can, without risk of nuisance, therefore, be placed on an adjacent site.

In the selection of the precise spot for the station, regard should be taken of the fact that, unless directly against the waterside, some expensive works may be necessary to bring in condensing water. Hence, since the Cattewater is a tidal inlet, it will be necessary to consider the exact position of the station with some care, and also it will, I think, be necessary to construct a quay or wharf, on which part of the station can be situated, at which wharf coal barges can discharge and easy access for condensing water be obtained. The general design for the station should be a building divided into engine-room and boiler-house, placed to as to be extended gradually from the waterside as required. The coal-store should lie between the railway and the wharf, and delivery of coal must be made without handling, a locomotive crane unloading from barge or railway truck into the coal-store direct. The important matter is to design the building in the first instance so that subsequent extension of the station may take place as required, without alteration or interference with the section already constructed.

The position on the Cattewater site will permit surface condensers to be employed, using the water of the Cattewater for circulating and returning the condensed water to a hot-well A considerable economy in coal will be effected by the employment of condensation. The chimney-shaft should be constructed at once large enough for the full output of the station. The station building should, in my opinion, be designed for an ultimate output equal to 30,000 8 c.p. lamps, but only about one third of the station erected at first, and provision made in the initial building in generating plant at first only for 7 500 8 c.p. lamps operated at one time or for about 10,000 lamps connected to the mains, with proper reserve plant. Although we may reckon an 8 c.p. lamp as taking about 32 watts, it is safe to make provision in the generating plant for 40 watts per 8 c.p. lamp This lamp load of 7,500 lamps at the safe reckoning of 40 watts generated per lamp corresponds to a working capacity of 300 kilowatts, or 400 with reserve plant. As regards the size of a unit of generating plant, I advise the adoption at first of one not larger than 75 or 100 kilowatt size, the corresponding engine being about 150 h.p. or 200 h.p. The alternators or dynamos should be direct-driven, as at the Portsmouth or Leicester Corporation stations—that is, no belts or ropes employed. These alternators should generate current at a pressure of 2,000 or 2,400 volts. The current should be transmitted by armoured concentric cables laid direct in the ground to transformer sub-stations, established in various parts of the town and where it will be reduced in pressure to 100 volts for distribution to the houses. These transformer sub stations will be small rooms, or dry cellars, which may be situated beneath buildings, or may be small separate underground chambers, in which the transformers will be placed. The distributing mains will be laid under the pavements on either side of the road, and from them the house services taken off. I should suggest the adoption of a plan I have carried out successfully at Taunton, where no junction-boxes are used at all, and hence no receptacle for the collection of gas, and therefore no risk of street-box explosions. This plan consists in making at once when the distributing cables are laid down a connection or service to every house.

The distributing mains are formed of concentric lead-covered and steel-armoured cable laid under the pavements, and are quickly laid, and give no trouble. I have considered very carefully the question of supply of electric current for power to private houses, shops, and places of business. As gas in Plymouth has a low price, the supply of electric power will have to compete against gas-engines served with cheap gas. I think that this may act to retard the growth of a demand for current for power in the daytime, and it has not been found that the sale of power in small units has progressed very fast in any of the provincial towns. If, however, further enquiry shows the necessity of meeting any demand for power in small units which cannot be met more cheaply by gas-motors, then I should suggest for adoption in this case a two phase alternating-current system, by which current, not only for light, but for power, can be distributed, if required. As regards the frequency of alternations my own strong preferences are for a moderate frequency, such as 50 periods per second, which has been adopted with success at Portsmouth, Ealing, and Derby.

The current would be brought from the electric station on the Cattewater to the transformer sub stations. One of these last might be placed in a cellar under the market, and from this one sub-centre all the compulsory street area in George street, Bedford-street, and Old Town-street could be lit. Service lines should be laid down on both sides of these streets, and a supply given in other neighbouring streets, if required. As regards a day supply, I strongly urge that it be not given at first, but that the electric service be only from dusk to dawn, as it is found by experience that in the initial stages of the business very great economy is effected by not adopting a 24-hour service. With respect to systems of charge it is very important to remember that electric supply differs in important particulars from gas and water supply, and the difference may be summed up as stated below in an extract taken from a report given by me to another corporation.

"In dealing with a public supply of electric current it has to be borne in mind that the conditions under which such a work is carried out are very different from the supply of such commodities as water and gas. Every lamp installed in a consumer's place has to be represented in the supply station by a certain amount of plant which is capable of providing electric current for that lamp at any time from sunset to sunrise; but the actual time during which a lamp is in use is a very small fraction of the time during which it might be in use. The value of a consumer to the electric supply station is not determined solely by the number of units he takes, nor by the number of lamps which he has installed, but by the average length of time which he uses the lamps he has in place The actual amount, therefore, of a consumer's bill is then no indication of the commercial value of that consumer to the supply station.

"Take, for instance, the case of two consumers, one of whom has 100 lamps installed in his shop, but who only uses them at an average of one hour per day for 300 days in the year, the amount taken by this customer during the year would therefore be 1,800 units, which at 6d. per unit is £45. Suppose, however, that another customer has only 25 lamps installed, but uses them at an average four hours per day; his bill during the year will be precisely the same as that of the first customer, but whereas the first customer requires the generating station to put down plant representing the possibility of a supply for 100 lamps, the second one only makes a requirement for 25 lamps in plant. The whole expenses of working the generating station may be divided into two parts. The first part comprises what may be called the fixed charges, which are the establishment charges for superintendence, interest on borrowed capital, and other items which hardly vary at all with the amount of the electrical energy sent out from a given electrical plant.

"In the second place, there are the variable charges, such as those for coal, oil, water, and engine-room stores, which vary almost proportionately with the electrical output of the station. Hence, it is clear that to make ends meet there must be, in the first place, a certain minimum of units made and sold, but that when these are bought and paid for every succeeding unit can be supplied at a very much less price, still allowing a margin for profit. The important question, therefore, in the commercial management of the station is this: How can we encourage those consumers who are taking the units which can be cheaply produced? This is not achieved simply by giving discounts on the total bill, because, as explained above, two consumers may have exactly equal bills, and yet one of them may have made a profit to the electric lighting station, and the other of them may actually have made a loss. This question has taxed the mind of every electrical engineer. A solution of the difficulty has been proposed by Mr. Wright, of Brighton, who has invented what he calls a demand meter. This demand meter is fixed in the consumer's house and it shows, not the total units taken by the consumer, but the average time during which a consumer has used the lamps installed in his house. A discount is then given on this basis: thus, for instance, at Brighton, every unit which is taken by the consumer for lamps burning less on an average than one hour per day is charged 7d, but all units taken by consumers for lamps which on an average burn more than one hour per day are charged 3d. per unit. In this way an encouragement is given to long hours of use, and a consumer has it in his power to moderate the charge to him by a use of the incandescent light, which effects an economy in the cost of production. Since this method of charging has been in force in Brighton the total consumption of units has increased fourfold in two years."

My recommendation on the subject of charge is that the full price in your order—viz. 8d. per unit—should be charged for the units supplied to all lamps which burn one hour or less per day, but that a reduction of 4d. per unit be made for all units supplied over and above the one hour per day for such lamps. At this rate the cost of current for an 8-c.p. 32-watt lamp used one hour a day on an average would be 7s. 9d. per annum, but if used two hours per day on an average the cost would be only 50 per cent. increased, and would be 11s. 8d. per annum.

Public and Private Lighting.

I hold the view very strongly that whenever a Corporation undertakes the electric supply, good street-lighting should form part of the scheme. Every ratepayer has an equal interest in good and well-arranged public lighting in the streets, and the adoption of a system of arc and incandescent lighting for the streets is, I consider, an essential matter. As regards the arc lighting plant, there is strong evidence in practice that arc lighting to be effective and economical must be conducted with continuous currents. If alternating currents are adopted for the private incandescent supply, then either separate arc light dynamos must be provided, or else, as at Portsmouth and other places, a device called a rectifier for converting part of the alternating current into direct current for the arc lighting.

The arc lamps should be carried on ornamental cast-iron poles and be placed alternately on either side of the street about 35 or 40 yards apart, or closer if the street lit is not moderately straight. The conductors for the arc lamps should be underground and consist of twin-armoured cable. The arcs should be on several separate circuits to avoid risk of simultaneous extinction. Side streets can be lit with series incandescent lamps off the arc light circuits.

Digitized by Google

I am strongly of opinion that arc lighting in the streets, squares, and on the Hoe should form part of any municipal scheme for electric lighting in Plymouth, and that such arc lighting should be conducted by what is called the series system with continuous currents, the currents being supplied either by separate arc lighting machines, direct driven, or by rectified alternating currents. I will not at the present moment commit myself to an opinion as to which of these methods should be selected, as it will, to some extent, depend on the tenders, but by either system it is possible to provide perfectly satisfactory public arc lighting, and the smaller streets can, if need be, be lit by incandescent lamps running in series with the arc lamps, and arc lights provided for the outside of public buildings.

Any interior arc lamps required would have to be alternating-current arc lamps, as the introduction of the high-tension current into buildings is not regarded favourably by the Board of Trade The cables for this arc lighting system should be armoured cables placed underground—the arc lamps being supported by ornamental cast-iron posts placed at the distances mentioned—the arc lamps being those which are termed 300-watt arcs. There is not the slightest doubt but that good arc lighting would form a great additional attraction to the public resorts in Plymouth.

(To be continued.)

COMPANIES' MEETINGS AND REPORTS.

WESTINGHOUSE ELECTRIC COMPANY, LIMITED.

The fifth annual general meeting of this Company was held on Tuesday last at the Company's offices, 32, Victoria-street, S.W., to receive the report and balance-sheet for the year ending September 30. The proceedings were formal, and the Press were not admitted. The report states that "the agreement between the English and American companies approved by the shareholders at the last general meeting has been carried out. After providing for all expenses of management, directors' fees, depreciation of stock and office furniture, patent taxes, and other expenses connected with the maintenance of the various English and foreign patents owned by the Company, there is a net profit for the year amounting to £7,725. 1s. 11d., which, added to the sum brought forward from the previous accounts, makes a total of £20,739. 18s. 7d. to the credit of profit and loss, which the directors propose to carry forward. Owing to the continued increase in the sales of the Shallenberger meter, the directors have found it necessary to provide more extensive laboratory accommodation, for the purpose of ensuring careful tests and adjustments of the meters being made before despatching them to purchasers. The sales of meters during 1894 have been satisfactory, and orders for transformers and other apparatus were also in excess of those of previous years. The directors have, as before, waived their right to one-half of the fees to which they are entitled under the articles of association. Mr. Oscar H. Baldwin, who was previously associated with the English company, has returned to London, and, on the recommendation of Mr. Westinghouse, has been appointed manager of the Company with a seat on the Board." The directors add that they "think the shareholders will be glad to know that they have purchased a controlling interest in the European patents, covering a new system of electric traction in which the conductors are placed underground, and which they believe will prove to be a very valuable asset."

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ashington.—Tenders are desired for the electric lighting of Miners' Hall, Ashington. Names and addresses should be sent at once to Messrs. Boolds and Hardy, architects and surveyors, Morpeth.

Madrid.—The Director of Public Works invites tenders by November 15 for the concession of the construction and working of a tramway from Madrid to Colmenar Viejo, with branches to Chamartin and Rosa. Security, 12,505 pesetas. Particulars at the Direccion General de Obras Publicas (Ministerio de Fomento), Madrid.

Saltash (Cornwall)—Tenders are wanted for lighting with gas, electricity, or otherwise the public lamps in the borough from January 4, 1896, for such term as may be agreed upon, for the Saltash Town Council. Number of lamps 81, with every prospect of the number being considerably increased at no distant date. For particulars apply to the chairman of the Works Committee, Mr. W. V. Alford, 3, Springfield-terrace, Saltash, to whom sealed and marked tenders should be sent by 26th inst.

Vienna.—The Government Commissioner, who at present takes the place of the Mayor of Vienna, invites plans and tenders for the construction of an electric city railway there. A detailed list of the lines which have to be built is given. They are to be circular, and are to form radii from the centre of the city to each of the suburbs, including the Prater, the Kahlenberg, and the great cemetery at the Semmering. All offers and plans must be addressed to the Vienna Town Hall before November 14.

London, E.C.—Tenders will be received at the General Post Office, London, E.C., until noon on 28th inst. (a) for supply of red fir telegraph poles, to be delivered in London, King's Lynn, or Sutton Bridge, and at Northumberland Dock (River Tyne), West Hartlepool, Hull, or Grimsby; and (b) for creosoting the poles with 10lb. or 12lb. of creosote to the cubic foot, as may be directed. The poles to be felled between November 1, 1895, and February 29, 1896, and to be delivered during the following summer at the port at which the creosoting is to be performed. Butt sections, from not less than three poles, to show the quality of timber offered, must precede or accompany the tender of any person who has not already supplied the Postmaster-General with poles. Forms of tender, containing all particulars, may be obtained on application to Mr. Chas E Stuart, controller of stores.

Glasgow—The Corporation desire tenders for the construction of a new line of tramways, commencing at the termination of the existing line of tramways at Rockvilla, and terminating at Saracen Cross, Possilpark; also tenders for electrically bonding the rail joints of the above tramways, for the Corporation of Glasgow. Specifications and forms of tender may be had from Mr. John Young, general manager, 88, Renfield-street, Glasgow, where drawings may be seen and any information obtained. Separate sealed tenders marked "Tramways—Tender for Possilpark Extension" and "Tramways—Tender for Rail Bonding," respectively, to be lodged with Mr. J. D. Marwick, town clerk, City Chambers, Glasgow, by 10 a.m. on 22nd inst.—The City Improvement Trustees are prepared to receive tenders for providing and fitting all the lamps, wires, etc., for lighting the new family home in St Andrew-street by electricity. Specifications and forms of tender may be had from Mr. William Arnot, electrical engineer, 75, Waterloo-street, Glasgow, and tenders must be sent in to the town clerk, City Chambers, Glasgow, by the 21st inst.

RESULTS OF TENDERS.

London, S.W.—The Metropolitan Asylums Board have placed with Messrs. Muirhead and Co the contract for the supply and fitting up, under the supervision of Dr. Hopkinson, of certain additional telephones at the new blocks of the Gore Farm Hospital. The amount is £72.—Subject to the consent of the Local Government Board, the same authority have accepted the tender of Callender's Bitumen Telegraph and Waterproof Company, Limited, to supply and lay two new cables for the electric light installation at the hospital ships, in accordance with a specification prepared by Dr. Hopkinson, at the sum of £125. Messrs. Callender undertake to recover four damaged cables at their own expense, and to allow the managers at the rate of 5d. per pound for the copper.

London, E C—Tenders to the Shoreditch Vestry have resulted as follow: (Section A) insulated electric mains; (B) conduits and drawing-in boxes, to be laid in the parish of Shoreditch. Messrs. Kincaid, Waller, and Manville, 29, Great George-street, Westminster, engineers: British Insulated Wire Company, Prescot, (for A and B), for high-tension wires and larger low-tension mains and for conduits (accepted); W. T. Glover and Co., Manchester (for A only), for smaller high-tension mains (accepted) Also tendered: India Rubber and Gutta Percha Company, Silvertown (for A and B); Fowler, Waring, and Co., North Woolwich (for A and B); Henley's Telegraph Construction Company, North Woolwich (for A and B); Callender Company, 101, Leadenhall-street, E C (for A and B); Siemens Bros. and Co, 12, Queen Anne's gate, Westminster (for A and B); Reed Bros., 12, Wharf-road, City-road, N. (for B only). At schedule prices.

Stafford.—The tenders for wiring and fitting the infirmary for electric light, for the Committee of the Staffordshire County Infirmary, were as follow:

Drake and Gorham, 66, Victoria-street, London (accepted)	£397	0	0
Bennett and Druce, 80, Winckley-square, Preston	319	0	0
Lomax, Kendal, and Co., 2, St. James's-square, Manchester	380	0	0
Paterson and Cooper, Victoria-street, London	381	10	0
Liverpool Gas Fittings Company, Duke-street, Liverpool	434	0	0
S. J. Waring and Sons, 118 and 120, Deansgate, Manchester	455	0	0
Corporation of Stafford Electricity Works, Stafford	491	15	3
Lea, Son, and Co., Pengwerne Works, Shrewsbury	442	0	0
F. W. Ball and Co., 3 Unity-street, College-green, Bristol	468	6	0
Strode and Co., 48, Osnaburgh-street, London, W.	500	0	0
Fowler, Lancaster, and Co., Graham street, Birmingham	475	0	0
Northern Counties Electrical Construction Company	586	10	0
Walsall Electrical Company, 57, Bridge-street, Walsall	523	15	0
T. S. Anderson, Royal Insurance Buildings, Sheffield	550	0	0
Fletcher, Hirst, and Co., Bankfield Works, Burnley	566	0	0
Laing, Wharton, and Down, 82A, New Bond-street, London, W.	618	0	0
Corlett Electrical Engineering Company, Wigan	615	0	0
Spagnoletti and Crooke, Goldhawk Works, Goldhawk-road, London	677	0	0
W. O. Rooper, Emery Works, Stafford	663	15	1
Benham and Sons, Wigmore-street, London, W.	836	0	0
Hall, Geary, and Co., Church Gresley, Burton-on-Trent	796	10	9

Wakefield.—At Tuesday's meeting of the Corporation the report submitted by Mr. Robert Hammond on the electric lighting tenders was considered. An interesting feature to be noticed was that the tenders of Messrs. Ferranti and Messrs. John Fowler for the engine-house plant were almost identical, being within £11 of each other, the amounts being £9,102 and £9,091 respectively. Mr. Hammond reported that either firm could be absolutely relied upon to turn out a first-class electrical job, and he left it to the committee to choose between the McLaren (horizontal) engines offered by Messrs. Ferranti and the Fowler engines

Digitized by Google

included in Messrs. Fowler's tender. After a sitting of three hours, during which the *pros* and *cons.* were thoroughly discussed, the committee eventually decided to give out the whole of the works plant to one contractor, and the following tenders were accepted :

Boiler-house plant, engine-house plant, switchboard, and instruments, Messrs. John Fowler and Co. (Leeds) Limited	£10,900	0	0
Cables, culverts, and trenching, British Insulated Wire Company, Limited	3,192	3	4
Transformers and distributing switchboard, Messrs. John Fowler and Co. (Leeds) Limited	448	0	0
Arc lamps and posts, Brush Electrical Engineering Company	252	10	0
Meters, Westinghouse Electric Company, Limited	233	18	3
Overhead crane, Mr. Thomas Smith, Rodley, Leeds,	253	0	0

Total, £15,279. 11s. 7d., as against £15,893, the amount of Mr. Hammond's estimate submitted to the Local Government Board. Messrs. Siemens Bros. and Co.'s tender for the whole of the job was within £7 of the latter figure—viz., £15,900. The very successful working of Messrs. Fowler's plant at the Leeds Electricity Works largely contributed to their selection for the most important portion of the plant.

Southmolton (Devon).—The following were the tenders for wiring the factory buildings for the electric light and ironing, including all the electric generating plant, for the Southmolton Shirt and Collar Manufacturing Company, Limited :

Newton and Hawkins, Taunton (accepted)	£282	0	0
Pettit and Hands, London	406	0	0
H. F. Joel and Co., London	394	0	0
Walsall Electrical Company, Walsall	412	4	0
G. Hill, Manchester	715	0	0
J. Glover and Co., London	457	13	0
Macdonald and Collidge, Gloucester	429	0	0
F. W. Ball, Bristol	550	0	0
Paterson and Cooper, London	515	0	0
Brush Electrical Engineering Company, London	565	10	0
Acme Immisch Electrical Works, London	415	0	0
J. C. Howell, Llanelly	558	0	0
W. L. Paterson, Newcastle-on-Tyne	352	0	0
Mavor and Coulson, Glasgow (without accumulators)	198	0	0
H. T. Sully, Bristol	322	0	0

Bedford.—The following were the tenders for the supply and delivery of 200 cast-iron lamp columns, carriers, and globes, for the Electric Lighting Committee :

Cast-iron tops.			
W. Bradley, Brighouse (accepted)	£449	0	0
Holham and Co., London	540	0	0
Phœnix Foundry Company, Derby	579	0	0
Alloa Iron Company, Alloa	620	0	0
Ulverston Shutter and Lift Company, Ulverston	625	0	0
Sharpe and Co., Lancaster	632	0	0
Newton, Chambers, and Co., Sheffield	650	0	0
Kilpin and Billson, Bedford	653	0	0
Pontifex and Co., London	700	0	0
Macfarlane and Co., Glasgow	811	13	4
Goddard, Massey, and Warner, Nottingham	850	0	0
Hart, Son, Peard, and Co., Birmingham	960	0	0
G. Smith and Co., Glasgow	1,050	0	0
Sheet copper tops.			
W. Bradley (accepted)	519	0	0
Hollam and Co.	660	0	0
Alloa Iron Company	715	0	0
Cochrane and Co., Dudley	650	0	0
Sharpe and Co.	782	0	0
Newton, Chambers, and Co.	800	0	0
Kilpin and Billson	765	0	0
Pontifex and Co.	950	0	0
Macfarlane and Co.	830	0	0
Lloyd's Works, Abercarn	563	6	8
Ashmore, Benson, Pease, and Co., Stockton	739	0	0
Goddard, Massey, and Warner	910	0	0
G. Smith and Co.	1,050	0	0
Mackenzie Bros., Edinburgh	1,350	0	0

Ayr.—Mr. E. G. Pink, the engineer, has reported to the Sub-Works Committee of the Town Council on the electric lighting of the town properties : "Specifications were sent to the four lowest tenderers for wiring the Municipal Buildings (see *Electrical Engineer* of September 13, p. 303), only three of whom submitted tenders. These are as follow : .

	Scottish Elec. Eng. Co. £ s. d.	M'Leod and Co. £ s. d.	W. G. Higgs and Co. £ s. d.
Wiring to points with fitting as per schedule	2 2 6	—	1 0 10
8, 16, or 32 c.p. lamps	—	0 18 6	—
Extra lamps	2 2 6	0 15 0	0 16 0
Ditto on new premises	2 2 6	0 18 6	0 16 0
Wiring only	—	—	0 12 9
Arc lamps	8 10 0	8 5 0	7 0 0

As none of the firms have submitted prices or designs of fittings, I recommend the acceptance of the lowest and only tender for wiring only—viz., that of Messrs. W. G. Higgs and Co., who are already carrying out the wiring of the Municipal Buildings most satisfactorily. Fittings to be selected. With reference to the arc lamps no details are given, and I recommend the acceptance of Messrs Higgs for the wiring only at £2. 4s. 6d. each. The arc lamps for the streets will be tested at Leeds on the 8th inst., and I should prefer to see them burning before adopting another type. It would be advisable to advertise for quotations for arc lamps suitable for our system, as there are many new designs in the market." On the motion of the chairman, the sub-committee have unanimously adopted the recommendations contained in the report. A minute of the Lighting and Hall Letting Committee states that "Mr. Higgs submitted a number of designs of electroliers for the Town Hall, and on the motion of Dean of Guild Girvin, seconded by Bailie Burns, the meeting unanimously adopted design No. 1, the diameter of which is to be 4ft. Mr. Higgs agreed to give a deduction of £27 from his original offer. The meeting agreed to adopt a fitting for the Council-hall and committee-room on the lines of design No. 1, a sketch and sample of which is to be submitted by Mr. Higgs for the approval of the chairman, town surveyor, and electrical engineer. Subject to approval of said design, the committee authorised the contract to be closed with Messrs. Higgs.

BUSINESS NOTES.

Morley.—The clock in the tower of the new Town Hall will be lighted by electricity.

Western and Brazilian Telegraph Company.—For the past week the receipts were £3,248.

Battersea.—The Vestry have decided to take the necessary steps to acquire power to light portions of the parish by electricity.

Gesellschaft fur Elektrische Unternehmungen, Berlin.—This Company proposes to issue new shares to the value of 15,000,000 marks.

Swadlincote (Derbyshire).—The Urban District Council have announced that the question of lighting Stanton by electricity is being considered.

Aberdeen.—The installation of the electric light which it is proposed to fit up in the public library will consist of 150 16-c.p. lamps, and cost £140.

Salt Lake and Ogden Gas and Electric Light Company, Limited.—Letters of allotment for the preference shares of this Company have been posted.

Southsea and Portsmouth Pyramidical Railway, Limited.—This Company, formed to work the Pyramidical Railway license for Southsea and Portsmouth, has been registered.

Partick (Lanark).—The Committee on Electric Lighting have recommended the Burgh Commissioners to await the result of the installation at Ayr before proceeding further with the matter.

Inverness.—The Town Council have unanimously resolved to oppose three applications which have been made to the Board of Trade by public companies to introduce the electric light into the town.

Swansea.—Mr. Leeder's motion for the recision of the decision to light the town by electricity was ruled out of order at Wednesday's meeting of the Town Council, as the question had been twice settled this year.

Hampton Wick.—The chairman of the District Council has mentioned that the Lighting Committee had not met yet, but would do so this month to consider the letters about electric light and other matters.

Appointment.—The Cork Corporation have appointed Mr. J. W. Smith to advise them on the electric lighting question. Mr. Smith may be recognised as engineer to Messrs. Calvert and Co., of Manchester.

Liverpool Overhead Railway.—The traffic receipts of this railway for the week ended 13th inst. amounted to £1,118, as compared with £906 in the corresponding week of last year, being an increase of £212.

Belfast.—The Electric Committee, under the chairmanship of Alderman Sir Daniel Dixon, D.L., have met and transacted routine business. We understand that further applications for the supply of electric light are continually coming in.

Bank-Lighting.—The electric lighting of the new Salvation Army bank has recently been carried out by Mr. Fredc. H. Taylor, A.I.E.E., of 17, Ironmonger-lane, E.C. The installation includes a 2,000-c p. arc lamp in the centre of the main hall.

St. James's and Pall Mall Electric Light Company.—The sale of electricity for the quarter ending September 29, 1895, representing the supply at 6d per unit, amounted to £7,402, as against £6,935 at the same rate for the corresponding period of 1894.

Manchester.—The Corporation have adopted a report of committee recommending the taking over of the tramways. An amendment to refer back to the committee to first ascertain whether it was desirable to substitute electrical for horse traction was lost.

Chelsea.—The Guardians have referred to the Finance Committee a letter from the Chelsea Electricity Supply Company suggesting that the new buildings should be wired, so that in the event of the Guardians deciding to use electric light there would be no difficulty.

Road and Rail Locomotive Company, Limited.—This Company has been registered with a capital of £1,000 in £10 shares. Object : to enter into an agreement for the acquisition of certain

Digitized by Google

inventions in relation to tram, road, and rail locomotives, etc., and to develop and turn to account the same. Registered office: 47, Chancery-lane, W.C.

West India and Panama Telegraph Company.—The directors of the West India and Panama Telegraph Company, Limited, have decided to recommend for the six months ended June 30 a dividend of 6s. on the first and second preference, and of 1s. 3d per share on the ordinary share.

City and South London Railway.—The returns for the week ended October 13 were £916, compared with £920 for the corresponding period of 1894, being a decrease of £4. The total receipts for the half-year 1895 are £12,774, compared with £12,931 for the corresponding period of 1894, being a decrease of £157.

The Proposed Electric Railway in Derbyshire.—The provisional committee appointed at a meeting held in Derby some time ago to consider a project for the construction of an electric railway between Derby and Ashbourne have called two other meetings. One is to be held at Derby to-day (Friday), and the other at Ashbourne to-morrow.

Llanelly.—With regard to the letter of Mr. J. C. Howell, asking upon what terms the Borough Council were prepared to part with their provisional order, the Estate Committee have considered the matter, and asked for powers to treat with Mr. Howell in the matter. Ultimately, it was decided that a committee of the whole Board should meet Mr. Howell.

Chester.—Lord Kelvin has sent in to the Town Council his account for £105, which was the agreed amount for his report on the electric lighting of the city. The amount had not been included in the other accounts that had come up for payment, and the Mayor therefore proposed that it should be added to the other bills for payment. This was carried.

Astrachan.—The "Adelsklub" has resolved to electrically light the new clubhouse. The plant, consisting of two horizontal single cylinder petroleum-engines (Kaselovsky patent), one shunt dynamo, and a battery of accumulators (Pollak system), is to be supplied by the Berliner Maschinenbau Aktiengesellschaft vormals L. Schwartzkopff, Berlin, through its agent in Astrachan, Herr Supuck.

Harrogate.—The Town Council have adopted the report of the electrical engineer upon the tenders for electrical works, and recommend that tenders be let for £13,302. The estimates amounted altogether to £27,000. The Council have also decided to apply for powers to borrow a further sum of £2,000 for electric lighting, making the total £27,000 to be borrowed instead of £25,000, as originally fixed.

Plymouth.—The Town Council on Monday discussed Dr. Fleming's report on the electric lighting of the town which appears elsewhere in our columns. Ultimately, a recommendation of the Works Committee was adopted, that the Council should depute the Electric Lighting Sub-Committee to visit some of the large and successful electric stations in London and the provinces before taking any further action.

Headland's Patent Electric Storage Battery Company, Limited.—This Company has been registered with a capital of £15,000 in £1 shares. Object: to acquire the business of electricians and electrical engineers as now carried on by H. and E Headland, at Leyton, Essex, and to develop and extend the same. Manager, H. W. Headland; remuneration, £4 per week Registered office: 12, Pall mall, S.W.

Telegraphic Interruption in Australia.—As a link in the communication with Australia and New Zealand, it would seem that the Western Australian land lines (which carry the traffic of the alternative cable laid to Rcebuck Bay) are not to be relied on. From last month's Australian Press we learn that this line was faulty, and that "business was much delayed," occasional batches of five or six messages only being received

Cheltenham.—Alderman Norman, in introducing the minutes of the Electric Light Committee, spoke of the proposed conference with the gas company and of the progress of the electric light. Mr. Margrett congratulated the committee on the proposal to extend their lighting scheme as far up the High street as the Belle Vue Hotel, while Mr. Feeney hoped that the lighting of Regent-street would be improved. The minutes were confirmed.

Southend.—Councillor Bowmaker has been appointed chairman of the Electric Light Committee of the Town Council. The committee requested the advice of an engineer, and suggested Mr. A. B. W. Kennedy, of 14, Old Queen-street, Westminster. The terms would be 100 guineas for the report; if the work were carried out, 5 per cent. on the capital outlay, with out of-pocket expenses. The report and recommendation were carried.

Hornsey.—The Lighting Committee of the Hornsey District Council having considered a report of the engineer on the experiments which had been carried out under the direction of the committee with regard to incandescent lighting as applied to gas lamps, have recommended that the experiments should be discontinued, and that the engineer should keep the committee informed of improvements which may be made in modes of lighting public streets.

Halstead (Essex).—The question of electricity *v.* gas has been reported on by the Lighting Committee of the Urban Council. They had heard from several towns, and they found both at Sudbury and Braintree a considerable difference made between public and private lighting. They had had reports from two engineers, and the question of electricity was still under consideration of the committee. It was resolved to appeal again to the gas company.

Copper.—In the first fortnight of this month the deliveries of copper amounted to 5,989 tons and the supplies to 5,909 tons; so that the visible stock of 52,763 tons is only 80 tons less than on September 30 and 203 tons smaller than it was a month ago. Thus the statistical position has had nothing to do with the moderate decline in the price of G.M.B's. The arrivals from America were small, but there has been a considerable increase in the Chili charters.

Madras.—The second section of the Madras electric tramway from Egmore to Triplicane, is being pushed on rapidly, and has reached Barber's Bridge. The section is expected to be ready for traffic by the end of the month, and as it will be worked on the overhead system, the posts to carry the conducting wire are already being erected. These posts are of drawn steel tubing, and will be 17ft above the road surface, so as to cause no obstruction to vehicles of any kind.

Brazilian Submarine Telegraph Company, Limited.—The accounts of this Company show a profit sufficient to enable the directors to recommend a final dividend of 3s. per share, making, with previous distributions, a total dividend of 6 per cent. for the year ending June 30, and also a bonus of 2s. per share, both free of income tax, which together will amount to £32,500, leaving a balance of £34,410, of which sum £30,000 has been placed to the reserve fund and £4,410 carried forward.

Yarmouth.—The surveyor has reported to the Town Council that 135 more lamps had been applied for, making a total of 5,495. The expenditure during September was £133. 4s. 10d., and the income £222. 0s. 6d. The profits for August and September amounted to £142. 4s. 7d., which just covers the loss on the first seven months' work. The profit to be earned during the rest of the year he estimated at nearly £300, making the cost of the electric lighting works to the ratepayers about £550 for the first year's work.

Whitehaven.—The engineer to the Town Council has read correspondence with Mr. C. M. Mayson, of Cockermouth, who was desirous of entering the electric lighting station as improver for 12 months, for which he was willing to pay a premium of £50, and it was resolved that the offer be accepted. The plans submitted by the engineer for alterations at the electric lighting station were considered, and his plan and estimate of the cost of carrying the cables outside the engine house, along the street in front and up the yard on the north-west and an estimate of the cost of ventilating the engine-house, were approved.

Isle of Man Tramways Company.—The Douglas Town Commissioners have confirmed a draft agreement of the lease of the Douglas Bay Tramways for 21 years from December, 1897, to the Isle of Man Tramways Company. The agreement also authorises the Company to construct and work a cable tramway to Upper Douglas, the Company in consideration to pay the Commissioners 15 per cent. on the gross takings of the Bay Tramway from January 1 last, with a minimum payment of £15,000 per annum, and as from January, 1902 5 per cent. on the receipts of the cable tramway. The Company agree to maintain Sunday service cars.

Brazil.—It is stated that Cataguazes is to be lighted by electricity; also the quarantine station at Ilha Grande On board the steamer "Merchant" there arrived at Pernambuco recently the electric light plant for the city of Maceió. The cost of the electric light plant for Pará is estimated at 3,200,000$000. The city will be illuminated with 1,800 incandescent lights of from 16 c.p. to 25 c.p., and 86 arc lights of 2,000 c.p. The power will be furnished by eight steam-engines, and will be sufficient not only for lighting the streets, but also for 10,000 private lights of 16 c.p. The plant will be furnished by the firm of Siemens and Halske, of Berlin.

West Australian Electrical Trunk Power and Lighting Company, Limited.—This Company has been registered with a capital of £510,000 in £1 shares (10,000 deferred). Object: to carry on in West Australia and elsewhere the business of an electric supply company in all its branches; as electricians, electrical and mechanical engineers, suppliers of electricity, etc.; as manufacturers of and dealers in wires, cables, primary, secondary, and other batteries, accumulators, lamps, and apparatus; also to carry on business as a gas and water supply company, and, further, the business of a mining, milling, and smelting company in all its branches.

Messrs. Baxendale and Co., of Miller-street Works, Manchester (a suggestive application of one of whose "Ship Canal" searchlights is described in another column), are, we understand, extremely busy with installation work, having in hand, amongst other contracts, the lighting of the Manchester and Salford Ship Canal Docks and sheds on the alternating high-tension system; Horrockses, Crewdson, and Co., Preston, incandescent lighting, complete plant; J. and N. Phillips, Manchester; H. Samuel, Manchester, Brockie-Pell arc lamps and Livonia flashing signs; the Oldham Town Hall; the Turkish Baths, Oldham; Hill and Sons' mills, Dublin; and Hope Bros., Manchester, etc.

Bradford.—A correspondent writes to a local paper: "I should like to ask if our borough electrical engineer or any of the Gas and Electricity Committee can give a satisfactory reason for altering the town supply from 115 volts to 220 There has already been spent about £50,000, if not more, on this luxury, and, now they have got a good supply, they must start spending more money, and also cause their consumers to do likewise. There were in the town, up to December last, about 37,000 incandescent lamps running at 115 volts. At whose expense are all these lamps going to be changed to 220 volts? I think it will be a great injustice if the ratepayer should have it to do just to suit a lot of men who love spending other people's money."

Ammeter Tests.—Mr. R. E. Crompton has recently completed a thorough test of three ampere-meters made by Messrs. Chamberlain and Hookham, Limited, of Birmingham, and reports that they start to register at ·15 of an ampere, and at ·33 ampere are only 20 per cent. slow. From this point onwards the maximum error in any one of the meters is 3·8 per cent. He concludes his report by stating that both as regards accuracy and mechanical fitness for its work the meter shows striking advances on any he had yet examined, and believes that it will be at the same time both durable and constant. Messrs. Venner and Sillar, of 10 Delahay-street, have been appointed London agents for the makers.

Wakefield.—In moving the minutes of the Electric Lighting Committee of the Corporation, which were adopted, Councillor J. L. Lee (chairman) said that steady progress was being made with the work. The tenders had come in, and had been inspected by the engineer. The prices were within the estimate. The committee hoped before long to have everything in order pending the decision of the Local Government Board as to borrowing powers. He could only urge the necessity of pushing on with the work, as there were some large customers waiting for the new light, who might provide it for themselves if the greatest expedition was not used. He hoped the buildings would soon be erected, and the works carried out to a successful issue.

Bolton.—The question of supplying electricity to the new station has been left to the chairman and vice-chairman of the Lighting and Electricity Committee and the engineer for consideration. A memorial from the inhabitants of Back Mary-street, off Derby-street, for street lamps was referred to the Lighting Sub-Committee. The electrical engineer (Mr. Rider) reports that there are now 81 connected consumers of electricity in the borough, and applications from nine other premises, making the total number of lamps 7,830 of 8 c.p. each. The maximum safe load of the present plant is only 4,800 8-c.p. lamps, and on the 4th inst. 1,930 lamps were burning at one time. Good progress is reported with the new engine and alternator.

Cardiff.—The Lighting Committee of the Town Council have received a letter from the Local Government Board stating that a public enquiry would be held in reference to the Council's application for permission to borrow £12,885 for electric lighting. Another letter received from the Local Government Board conveys sanction for the Council to borrow £3,500 for purchasing an electric lighting station in Womanby-street, the property of Messrs Brain and Co. A communication was received from Mr. T. M Hayward, Cathedral-road, stating that, on the understanding that the Council were going to bring the electric light mains down the road, he had fitted his place with wires. It was decided that the desires of the inhabitants as to using the light should be ascertained.

Barrow.—The new telephone trunk line has now been completed between Barrow and Whitehaven. This opens up direct connection with all parts of England, Scotland, Ireland, and Wales. The work of putting down the new trunk line has been carried out under the personal supervision of Mr. Chambers, of Whitehaven, the district manager for Cumberland, Westmoreland, and the Furness district for the National Telephone Company. The line is open for the use of subscribers, and has already been taken considerable advantage of. The Barrow exchange will now become an important centre of telephonic operations, not only by reason of an increase in the number of local messages, but as being an intermediate place between the Lancaster and Whitehaven trunk lines.

Braintree.—The surveyor to the Urban Council has stated that he found that at Braintree and Sudbury there was a considerable difference made between the price of gas to the public authorities and private persons. The surveyor was directed to again apply for a reduction of the price of gas. The chairman read a letter from Mr. Paynter, a gentleman who has recently taken Blue Bridge, Halstead, saying that the writer understood the Council were contemplating substituting electric light for gas in the streets, and he would be glad to act as the electrical engineer, as he had occupied a similar post abroad for many years. The clerk was directed to reply to Mr. Paynter, thanking him for his communication, and stating that the Council had not arrived at any resolution on the matter.

Portsmouth.—Alderman Ellis, speaking on the Corporation Electric Light Committee's report, said that the committee had purchased a Parsons turbo-alternator and generator for £1,750, of which £1,250 had been paid. The people living near the station had complained of the noise, and the committee, therefore, wanted permission for Messrs. Parsons to take back the condenser for a further £100. There would then be a balance of £400. A new surface condenser, noiseless, and more economical of coal and water, was proposed. It would cost a little more than the balance. The proposal was agreed to. The committee asked to be authorised to cut off the supply of electricity to any premises after giving seven days' notice. Alderman Ellis said this was necessary after "the parody of justice" they recently had in the County Court. Agreed to.

Killarney.—There is to be a contest in connection with the annual election of Town Commissioners. Each year four commissioners retire by rotation at this period, and until the vacancies are filled a good deal of local excitement prevails. During late years the election is mainly fought on the public lighting question, which is an important financial matter for the ratepayers. This will be the issue this year also, as the electric light company will endeavour to obtain a majority on the Municipal Board, and the gas company will exert their best endeavours in the same direction. As the Commission has been constituted it would appear to be equally divided on the lighting question, but of the four men retiring two are gasmen and two are supporters of the electric light. The result of the election, therefore will affect the power of either light on the Commission.

Electric Cranes.—An experiment is being made in London by a firm of wood merchants in the use of electricity for working the crane with which they stack their timber. They have found that manual labour is too slow, and that the use of steam power adds greatly to the cost of fire insurance. With their electrical crane they can lift loads of 15cwt. a height of 60ft., and so far as the trial has gone the crane has worked very satisfactorily. By means of levers, four different motions can be imparted. The dynamo from which the crane is worked is used in the evenings for the lighting of the works and offices Messrs. Glover and Co., of Hatcham Sawmills, who have made the experiment, believe that the crane will effect a considerable saving. In order that the workmen may have no grievance at the introduction of the apparatus, one-half of the difference in the cost of stacking the wood is to be handed over to them.

Wilmslow (Cheshire).—Mr. Ross has introduced a proposal to light the village by electricity. He submitted to the Urban District Council a draft agreement and a communication from the managing director of the Edison-Swan Company, in which they made an offer to the Council in case they applied to the Board of Trade for a provisional order, and consented to transfer the same to nominees, and would also guarantee the cost of obtaining the order, provided that such cost did not exceed £300. He spoke of the advantages to be gained if the place were lighted by electricity, and moved a resolution to the effect that the Council should apply for a provisional order to the Board of Trade. Mr. Fletcher, although in favour of applying for a provisional order, suggested that a committee should be appointed to deal with the question. Ultimately this course was decided upon, but on the motion of Mr. Clare it was decided to defer the matter for 12 months.

Woking.—The surveyor to the Urban District Council has reported that he had attended a meeting of the ratepayers of the St. John's and Goldsworth Ward, held to consider the proposal of the Council to light the ward. Estimates as to the cost of lighting with oil or electric light were submitted—viz. a rate of 6d. in the pound for oil, and 11d. for the electric light. The meeting unanimously resolved that the district should be lighted by electricity. He had obtained a tender from Messrs. New and Mayne, who estimated that the cost of erecting the standards as marked on the Ordnance map, would be £260, and the supply of current would be £4. 4s. per lamp of 2,200 hours, the same as in the Station District. The capital expenditure would be met by equal half-yearly instalments spread over a period of seven years. This represented an annual payment of £44. 18s. 8d, plus £168 for current, giving a total of £212 18s. 8d to be raised annually. The assessable value of the district was £4,606.

Kingsteignton (Devon).—A correspondent writes to a local paper: "Now that the water-supply question is finally set at rest after so many years' controversy, another matter of little less import comes to the front to take its place—the lighting of the village. Last winter we dwelt in Cimmerian darkness, and might as well have been living in the midst of Dartmoor, or at the North Pole Now we have a "Parish Council" (whatever that may mean), and there are some half-dozen paraffin lamps lighted in the High-street. They generally smell, not to say stink, and with any wind either smoke or blow out Will someone suggest to the Parish Council that the much-abused stream that flows through this village is quite capable of turning a turbine wheel, and generating sufficient electricity to, at a small cost, efficiently light the whole place, the first outlay being the only expense. The particulars may easily be obtained from Chagford, which is already lighted by electricity."

Waterford.—The Street Committee of the Corporation recommended that the application of the National Telephone Company to carry out a scheme for providing telephonic communication throughout the city be granted on their providing a free wire to Tycor and indemnifying the Corporation against all risk. The Mayor said the application of the company was of a very general and indefinite character. He suggested that, while they gave a general consent to the undertaking, they should ask for much more definite information than they possessed at present. They should exercise a stricter control over companies to whom it was proposed to give such a monopoly as in this case. Of course, it was right that an undertaking for the general benefit should not be impeded, but still the Corporation had a number of matters which they should look after and rights to conserve. It was decided to refer the matter back to the committee with instructions to obtain further information as to the projected works.

Chichester.—Councillor Edney has drawn attention to an item of £31. 10s., the cost of obtaining advice in connection with the subject of electric lighting. He also mentioned that a copy of the report which the Council had printed at the time had never been forwarded to him. Councillor Butler gave it as his opinion that the £31. 10s. for electric lighting advice was simply money spent to satisfy Councillor Prior's ambition. Councillor Prior observed that when the advice was obtained it was with a view of relighting the newly-added district, as it was thought before gas lamps were provided it would be better to ascertain the cost of electricity. The advice certainly cost the Corporation £31. 10s., but the money was not thrown away, because immediately afterwards the gas company lowered their prices to a considerable extent, and the city was a great gainer thereby. The advice was always at the service of the Council. His motion at the time was not, he was sorry to say, accepted, but he hoped at some future time the Council would take it up.

Stafford.—The ceremony of formally opening the Stafford Corporation electric lighting works was performed on Tuesday last by the Mayor (Mr. C. H. Wright) in the presence of a large number of people. The Mayor and the members of the Corporation assembled at the Guildhall and thence walked in procession to the works. On arriving at the works Mr. W. H. Peach, the chairman of the Electricity Committee, was presented with a silver key, with which he opened the entrance door and admitted the public. An address, in which he traced the history of the enterprise, was delivered by Mr. W. H. Peach. The Mayor then started the first engine, and the Mayoress, a silver key having been presented to her for the purpose, switched on the light. The second and third engines were started by Alderman Silvester and Mr. G. Wormal (ex-mayor). The engines having been stopped, the Mayor declared the station open. Various toasts were then proposed, and subsequently the chairman of the Estates and Works Committee, Mr. Smallman, switched on the arc lamps in Gaol-square. The engine room was tastefully decorated for the occasion, and a number of interesting exhibits had been arranged by the electrical engineer.

Bath —The chairman of the Markets Committee has announced the receipt of a letter from Mr. Alex McTavish, electric light engineer, asking to be allowed to light the markets, the power to be obtained by means of an independent gas-engine He (the chairman) said that a dynamo was to be erected in the technical schools, and arrangements had been made to bring the wires through the roof of the avenue, but they would not be able to get the lighting done from this source until after Christmas, as the room required in the basement would not be ready for use until then. It was decided to hear Mr. McTavish who was in attendance, and from his statement it appeared that a gas-engine and plant could be laid down at an initial cost of £250, and there would be a cost subsequently of 6d. an hour for gas while the engine was working The engine would require but little attention. The cost of carbons and other incidentals would be about £1 a month. After some discussion it was decided to ask Mr. McTavish to bring up a report. In reply to Mr. Tonkin, statistics were given as to the cost of lighting the markets by gas, and from a subsequent revision it appeared that this was £51 2s. 6d. for the year ended September 25 last. The Corporation's bill for the electric light during the past quarter amounts to £514.

Competition. — The Vestry of St. Mary, Battersea, offer premiums of £50, £30, and £15 for the three best schemes, reports, designs, and estimates for electrically lighting the parish of Battersea. The first selected scheme, design, etc., is to become the property of the Vestry, and if the Vestry engage the competitor to carry out his scheme the premium is to merge into and form part of the commission or remuneration to be paid him. The instructions may be obtained at the Municipal Buildings, Lavender-hill, S.W., upon payment of £3. 3s., which amount will be returned after receipt of a *bonâ fide* scheme, report, etc., in accordance with the terms of the instructions. The schemes, etc , will be submitted to an independent engineer of eminence, who will advise the Vestry in their choice. The schemes must be delivered to Mr. W. Marcus Wilkins, vestry clerk, Municipal Buildings, Lavender-hill, S.W., without motto or distinguishing mark of any kind, but accompanied by the author's name and address in a sealed envelope (unaddressed), before 12 noon on December 12, free of expense to the Vestry and at the risk of competitors, and no schemes or other documents will be received after that day and hour. Canvassing any member of the Vestry or any person employed to advise in connection with the undertaking will be a disqualification.

The National Telephone Company, Limited, against whom proceedings for allowing a nuisance on their works at Spitalfields had been taken by the sanitary authority of the parish, have appeared again at Worship-street Police Court by their representative. The prosecution relied on the evidence of two sanitary inspectors to show that an objectionable effluvium was traceable to the works of the Company, where it was found that a process of vulcanising was carried on. The defence established the fact that the sanitary inspectors lived in the same house, in the same street as the Company's works, and within two doors, that they had so lived for years, and made no complaint, that the street was adjacent to Spitalfields Market, that a large stable was in the immediate neighbourhood, that an ash-heap and a manure pit existed within 40 yards of the officers' dwelling, and that another stable and a margarine factory were contiguous to the works of the Company. Mr. Bushby (the magistrate) having gone over the evidence, found there was no preponderating evidence on either side. In addition, he found that it was some time since complaint of the nuisance was made, and he had not been able to learn that the premises had been similarly used since; in fact, that the use was discontinued That being so, he thought this was not a case in which he should interfere, and it would therefore be dismissed, defendants' costs being refused.

Brandon and Byshottles (Durham).—A lengthy report has been received from the Corlett Electrical Engineering Company by the Urban District Council as to the lighting of the district, showing that the cost would be cheaper than that of gas In connection with the question a letter was read from Mr. E. C. Martin, clerk to the Witton Gilbert Parish Council, calling attention to the monopoly held by the Durham Gas Company in regard to the supply of gas under the old Act of Parliament of the Durham Gas Company, which had recently been manifested by the Witton Gilbert Council, inasmuch as the gas company strenuously held to their sole right to supply gas lighting in this district, and at double the cost the Council could have had it locally. The result was they had had to resort to electric lighting, and the Council thought it their right and duty to explain what they thought was a very great hardship on the part of the directors. Mr. Potts said their first consideration was as to whether they were going to accept a scheme, and they must decide whether it had to be electricity or oil. Mr. Galbraith said it was not the best policy to go back to that antiquated form of lighting the district by oil. He had also spoken to colliery managers and several experienced people who had electric lighting under their control, and their experience would not warrant them in giving much encouragement in this direction, not, at least, in their conversation with him. It was eventually resolved that the district be lighted, and that a special meeting of the Council be held to definitely decide by what means the lighting shall be effected.

Neston and Parkgate (Cheshire).—Mr. Grenfell again brought before the Urban District Council the question of electric lighting. He had recently sojourned in a small village in the Pyrenees, something like Parkgate. There was not a rich man in the place—in fact, their medical officer of health would condemn most of the dwellings, yet every house in this village had the electric light. There was one main switch connected with every room where the light was used, and the whole of the lights "blazed out" at once, and were extinguished at the same moment, so that there was no possibility of anyone stealing the light. After the electric light was extinguished they had to use such other lights as they had. There was no meter or anything of that kind, simply a charge of 1d. per light per night, and the whole of the work was done by the parish commune. When he was there in 1894 the village was in darkness, as there was then no public lighting of any kind. He thought they might reasonably adopt something of the kind at Neston. The village referred to had water-power handy, but in Neston they had cheap fuel, whereas at the village coal was £5 per ton. The chairman said that the lighting of the lamps alone cost them 25s. per week. Mr. Grenfell said he had communicated with a consulting engineer in London, and had agreed to pay him £5 to visit the neighbourhood and go into the matter. The engineer wished for a very small committee, and he (Mr. Grenfell) suggested that the latter should consist of Mr. Churton and Mr. Jameson. It was arranged that these gentlemen should serve on the committee. Mr. Grenfell remarked that a number of the tradesmen would take the light if it could be supplied at a reasonable cost.

Romford.—Mr. Westgate has proposed that the Urban Council should take the necessary steps to obtain powers to use the electric light for the parish of Romford. Mr. Stone seconded the proposition. The Chairman said that at the last meeting he expressed the opinion that the Board of Trade would not grant the power, seeing that they did not intend to carry out the work immediately. He thought that Mr. Westgate moved his proposition in order to prevent any other company coming in. Mr. Westgate said that was not so. Mr. Smith said a proposition almost identical with that proposed by Mr. Westgate was brought forward in 1882 by the Local Board. The opinion then expressed was that the matter should not be taken in hand, and during the 13 years that had intervened nothing had been done in the matter. He thought the Board of Trade would not consent to such a "dog-in-the-manger" policy as that proposed by Mr. Westgate. He proposed, as an amendment, that the Council do not deem it expedient or desirable to take any steps requisite for the purpose of using the electric light for Romford. The amendment was not seconded. Mr. Stone did not think it advisable for them to incur any great expense, but he thought they ought to take steps in the matter, as the time would come when they would have the electric light in Romford. Mr. Westgate said that as the times were advancing they must advance. The idea that they would be asking for the provisional order for the sake of keeping others out was ridiculous. The Chairman said he had hoped Mr. Westgate would have given some reasons for his proposal, and also have gone into the question of the expense of getting the electric light and the cost of maintaining it. The proposition was lost, only the proposer and seconder voting for it.

Taunton —The Electric Committee of the Corporation have reported that an application had been received from Mr. H. G. Turner, of Pinkhurst, to lay on the electric light to his houses at Staplegrove. As the houses are in the electric lighting area, the committee recommended the Council to lay an electric lighting main along the public roads from Elm-grove to Pinkhurst in order to supply his residence and other property in Staplegrove, provided that he will pay 5 per cent. upon the outlay, but when the income from private lighting in that district reaches £50 a year the percentage is to cease. The Corporation are to be at liberty to use the main for public as well as private lighting. The committee reported that they had accepted Mr. S. Garford as an articled pupil for three years at a premium of £100; no salary to be paid him for the first year, £20 for the second year, and £40 for the third year. The committee presented the indenture of apprenticeship, and recommended that the common seal of the borough be affixed thereto. The committee have instructed the town clerk to write to the Board of Trade informing them of the works which have been done with respect to laying underground mains and removing the overhead wires, and asking them for a further extension of one year as regards the remainder. The committee have also requested the Finance Committee to take the necessary steps for raising a further sum of £3,000, this being the balance of the £5 000 sanctioned by the Local Government Board in December last. Alderman Standfast asked what would be the cost of the laying of the new main, and Councillor Potter explained that it would be about £150 or £200. He could not say the exact sum, because it depended upon the way they laid the mains, and also upon the arrangements made between Mr. Turner and the Water Committee. The application of Mr. Turner was

Digitized by Google

then granted, and the remainder of the recommendations of the committee adopted.

Wimbledon.—A public meeting, convened by the Wimbledon Ratepayers' Association in opposition to the electric lighting scheme adopted by the Wimbledon District Council, has been held in the Drill Hall, Wimbledon. Mr. T. C. Summerhays presided. The following resolution was proposed and seconded: "That this representative meeting of ratepayers having heard the objections raised against the electric lighting scheme of Mr. Preece recently approved by the Wimbledon District Council is of opinion that the same be opposed at the Local Government Board enquiry." Mr. Preece, who prepared the scheme for the District Council, rose to address the meeting. Replying to Mr. Cooke, he said it was not necessary to provide a special renewal fund in addition to the repairing fund. The Council borrowed its capital for 25 years, and in paying that off year by year they were paying off the cost of the machinery; hence it was unnecessary to have a sinking fund in addition. Mr. Cooke's point as to the engineer's salary arose from misapprehension arising from the manner in which the accounts had been drawn up. But the accounts were drawn up according to the Board of Trade requirements, and he was not responsible for the method. The actual salary paid to the engineer would be not £100, but £250 per annum. Mr. Crickmay asked what provision was to be made for private lighting in those streets where a separate private lighting main was not going to be laid down Mr. Preece replied that the public lighting mains might be tapped without any detriment to the street lamps, because provision had been made in these mains for supplying in addition to the street lamps no less than 10,000 private lights. Mr. Preece attempted to proceed, but was interrupted by cries of "Vote!" and he was obliged to sit down without further replying to his critics. It was then about a quarter past 10 o'clock, and the Chairman, without further delay, put the resolution to the meeting, and declared it carried almost unanimously.

Birmingham.—With reference to the brief account of the electrical installation at the new technical school in Suffolk-street which we gave in our last issue (p. 427), we should state that the generating plant consists of three Tangye gas-engines, each capable of developing continuously at least 53 b.h.p. when running at 160 revolutions per minute. Each engine has two heavy flywheels, 7ft. in diameter and 10in. wide. The three engines, together with three compound-wound dynamos, by Thomas Parker, Limited, of Wolverhampton, are placed in a room in the sub-basement. The dynamos run at 900 revolutions per minute, and are driven by leather belts running on to compound iron and leather dynamo pulleys, designed to prevent slipping while running with slack belts. Very massive fly-wheels are applied to these dynamos, each 4ft. in diameter, and having solid rims 8in. by 8in, including weldless steel hoops shrunk over. Gas is brought into the building from the street mains through a cast-iron pipe 7in. in diameter. Instead of the cylindrical cooling vessels usually supplied with gas-engines a large cast-iron tank 24ft by 3ft. deep, holding 6,000 gallons of water, is placed above the battery-room, of which it forms the roof A gallery erected above the dynamos carries the switchboard. Special connections are employed for enabling the three dynamos to be run in parallel. At one end of the gallery is a combined motor and dynamo, which takes a part of the current from the main dynamos and charges 58 storage battery cells, which were made by the Electrical Power Storage Company, Limited, of London, each cell containing 34 plates, and being of the central-station type. These cells are for lighting the corridors, staircases, and such rooms as may require artificial light when the machinery is not running. They are only capable of supplying a small proportion of the total number of lamps installed. As soon as the demand reaches about 100 amperes one of the main engines is started, and another and a third if required With regard to the lighting of the building, there is considerable variety—a circumstance which greatly adds to the educational value of the installation. In various rooms use is made of 16-c.p. incandescent lamps, 50-c.p. incandescent lamps, Crompton arc lamps of the ordinary pattern, and inverted arc lamps. The last have large reflectors underneath, which throw the light upon whitened ceilings, the illumination being thus indirect, and a beautifully soft light is obtained, with an effect resembling ordinary daylight. In the mechanical drawing office this kind of light is much appreciated, and in many of the workshops, where the shadows cast by the ordinary lights are objectionable. Electricity is used in the school for motive power purposes. Thus there are 15 electric motors in the building of a total of 46 h.p. In the electric engineering room there will be an admirable set of machines specially arranged by Dr. Sumpner (the principal). Here the electrical connections have been so designed that each machine can be used either as a dynamo or as a motor. Continuous and alternating currents will be produced by these machines for experimental purposes. A separate set of storage batteries and a specially arranged switchboard help to render this room very complete for its intended purpose. No one can see the electric motors without being struck by the convenience of the system of distributing power by electricity. It would have been quite impracticable to have conveyed the power throughout this building by means of lines of shafting and belts. The motors are started instantly and stopped as quickly, and require hardly more attention than a common blowing-fan.

Reigate.—A special meeting of the Council of the borough of Reigate has been held in the Market Hall, Redhill, for the purpose of considering the question of electric lighting for the borough. The town clerk read a letter from Messrs Charles J Grist and Co., of 20, Gracechurch-street, London, E.C., dated May 21, which was presented to the Council at the time, stating that they had been approached by several of the inhabitants of Reigate with reference to the electric light, and that they were thinking of applying to the Board of Trade for a provisional order to supply the current, and would propose laying mains in the following roads: London-road (Yew Tree end), London-road (Bell street end), Somers'-road, Castle-road, High-street, Wray Park-road Birkheads-road, Raglan-road, Alders-road, Alma-road. Church-road, Doods-hill or Croydon-road, Reigate-road, Bell-street. Of course, they added, the matter was only in embryo, but they were writing to ask the Council to give their consent before they (Messrs. Grist and Co.) gave notice of their intention to apply for a provisional order within a certain specified time Further correspondence presented included a notice from the Guildford Electricity Supply Company; letters, with enclosures, from the Town and Village Electric Light and Power Company, Limited; a letter from Mr. F. J. Warden-Stevens to the Mayor; and a circular letter from the Incandescent Light Company, Limited. The next item on the agenda was—"Matter to be brought forward by the Mayor 'To consider the expediency of applying to the Board of Trade pursuant to the Electric Lighting Acts, 1882 and 1888, for a license or provisional order authorising the Urban District Council for the borough to supply electricity within the area of the said borough, for public or private purposes, or for both such purposes.'" His worship explained that, as the Council were all aware, this meeting had been called in consequence of a resolution that was passed some months since by the Council requesting him to convene a meeting. He would ask some member of the Council to propose any motion that he wished to submit. Councillor Powell moved, "That the Council appoint a sub-committee to enquire into the matter of supplying electric lighting in the borough, and report on the same to the Council; and that the sub-committee be empowered to employ a professional electrical engineer to advise as to cost, etc." He need not, he said, adduce very many arguments in favour of the electric light. There was no doubt that up to the present time it was the best light that had been invented. The motion was carried after a long debate. Upon the proposition of Councillor Gilbert it was then resolved by 15 votes against 3 that the town clerk obtain counsel's advice as to the legality of gas shareholders voting upon the question. Alderman Pym and Yerworth and Councillors Barnes, Powell, Viall, Meier, Holman, Giles Gillham, Apted, Sanders, and Richardson were appointed the sub-committee, the Mayor stating it would have to be reconstituted on November 9.

Dover.—The Managing Committee of the Town Council have discussed the question of the construction of an electric tram in Dover. Councillor G. Fry moved that the town clerk be requested to obtain parliamentary powers to construct a tramway in the borough, and to work the same by other than horse power. He said that he thought the time had now arrived when they could safely construct a tramway from the pier to Buckland with a branch to Maxton through Priory-street or Worthington's-lane. They could not have done it before, and it was only due to the widening of Cannon-street and Biggin-street that they were able to effect it. During the last six or eight months the question of traction had very much developed, and he had just got a report from his managers in London and Ireland, who had been on the Continent, and had visited France, Holland, Germany, and Belgium, to report on the mode of traction in the various tramways in those countries, from which it seemed that the system of traction that was the easiest and the least expensive was by electricity. He did not propose to utilise the works in Maison Dieu-road to obtain the power, but if this was carried—and he was only shadowing forth at present his proposition, so that the Council could be perfectly *au fait* with the subject—he should propose that they should create the power on either of the vacant spaces at the top of Worthington's lane or at the rear of the Red Cow. He then proceeded to read an extract from a report pointing out the ease with which the tram was steered and that it could be promptly brought up. It ascended heavy gradients with facility. The tram could be turned with ease on a turntable, and there was no noise or smoke He offered to show any member of the Council the tramway at work at 32, Queen Victoria-street, on a miniature scale, and they could there easily understand and see how simple it was. The Mayor could tell them that the grand harbour of refuge was a practical fact and settled to be done, and that there were now some 20 gentlemen at work making a detailed survey, and within a very short period estimates would be obtained and the work would be in hand. Some hundreds of thousands of pounds would be voted in order that the work could be proceeded with with the greatest despatch and be completed within 10 years, and when completed they would have one of the finest harbours of refuge on the coast, and costing many millions of money. As a matter of course it would necessitate the employment of a very large number of workmen. If they did not take this matter in hand, someone else would. The cost of the power for running a car from the pier to Buckland was at the rate of 1¼d. per mile, and would therefore be 2½d., and they would carry 36 passengers. He would not ask them to pass a resolution that day, but he hoped they would consider it and authorise Mr. Knocker to obtain the parliamentary powers, which would cost from £300 to £500, the latter about the maximum. The Town Clerk remarked that he thought only a provisional order would be required, as he believed the power would only be granted from time to time. Councillor Fry said he thought a small committee should be formed to go into details, and enable the Council to come to a conclusion whether it was a right and proper thing in the interests of the ratepayers and working classes that they should construct this tramway. He thought they might

Digitized by Google

take it from him that it would cost about £8,000 per mile. The cost of the construction of the buildings, land, and machines would be about £10,000, and practically there would be a total outlay of from £36,000 to £40,000; but even supposing it cost £50,000, in borrowing the money at 3 per cent. and spreading the repayments over a number of years, and looking at the small cost of working, and that almost everyone would ride in the trams, he thought that there would not be any fear that they would not pay. He had been connected with trams for the last 30 years, and was chairman of one of the principal companies in London, and vice chairman of the Irish company and another in the south of London, and he had some experience, and knew that he was advising them for the good of the town and the benefit of the working classes. It was eventually ordered that Councillor Fry's notice of motion should be placed on the agenda on November 9.

Monmouth.—The Town Council have received the following letter from the Local Government Board: "Sir,—I am directed by the Local Government Board to state that they have had under their consideration the report made by their inspector Colonel Ducat, after the enquiry held by him with reference to the application of the Town Council of Monmouth for sanction to borrow £20 000 for purposes of sewage and electric lighting. Having regard to the local objections that have been made to the scheme so far as it relates to electric lighting, the Board, before further considering the application, desire to be furnished with a careful estimate of the annual outlay and receipts on that scheme alone. For this purpose it should be assumed, for the time being, that the entire capital outlay in connection with the mill is required for the electric lighting scheme, and the annual charge for the repayment of, and payment of interest on, the loan for this purpose should be debited to the electric lighting account. The Board request that the item which will be put forward as representing the income from the sale of electric light may be supported by more definite evidence than has yet been given of the number of lights which will be taken by consumers, and of the payments which will be received for them. Any actual promises to take lights in the event of the scheme being carried through should be separated from the cases where the figures are based only on an estimate. As regards the sewerage and sewage-disposal scheme, I am to enquire what would be the detailed estimate of its cost in each of the following cases: (*a*) if the electric lighting scheme were omitted altogether, but the use of the proposed water power were continued, solely in connection with the sewerage scheme and the repayments of the loan charged solely to that account; (*b*) if no water power were used, and the force for pumping the sewage were derived solely from engines.—ALFRED D. ADRIAN, assistant secretary." The annexed extracts are from the Council's reply: "My Council have to say that the estimate of the first cost of the electric lighting scheme suitable for supplying 2,500 lamps, each of 8 c.p., or their equivalent, installed is the sum of £5,600. The revenue to be derived is as follows: Amount at present expended annually for gas in street-lighting, which will go to the credit of electric lighting when the gas is replaced by electricity, £329. In addition to this there is an equivalent of 160 8-c.p. lamps which are under corporate control, which it is estimated will earn £56. Amount of revenue under corporate control, £385. The above lighting will absorb the equivalent of, say, 600 8 c.p. lamps, leaving therefore 1,900 to be distributed among private customers When the whole of these 1,900 lamps are taken up, the revenue to to be obtained from them may be estimated at 6s. 8d. per 8-c.p. lamp per annum, or £633. 6s. 8d. This, when added to the above £385, makes a total revenue to be derived from electric lighting of £1,018. 6s. 8d. Further, in the foregoing statement no credit is taken for three items of revenue which will be earned by the electric light installation if both schemes are carried out jointly: (1) the pumping of the water for market purposes at present obtained from the company—this equals £50 per annum; (2) the cost of pumping the sewage—this is estimated to be at least £150 per annum; (3) promises to date for motive power—value, £25 per annum. If the sewage scheme is alone to be sanctioned, the Council would not propose to use the water at the Old Forge Mill at all. Its distance from the site of the proposed sewage station is so great that no economy at all, but an increase of expenditure would result from the use of this water power. The estimated cost of the sewage schemes alone is £12,000, and, allowing 5 per cent. for the payment of capital with interest on the same and adding the working expenses (estimated at £308 per annum), a total annual cost of £908 per annum is reached—equal to a rate of 12 pence in the one pound sterling. It must be remembered that the whole intention of establishing the electric lighting scheme in conjunction with the sewage scheme is to thereby lower the cost to the rates of establishing the sewage scheme alone, and in connection with this it must also be remembered that the electrical machinery can be employed during the hours of daylight to pump the sewage (this being the time when the sewage is produced), the same machinery being employed to earn revenue from electric lighting during the hours of darkness, when practically no sewage is produced.—T. R. OAKLEY, town clerk."

Leeds.—As we announced last week, the Leeds City Council passed a resolution authorising the sale of the electric lighting plant now in the Municipal Buildings, with the exception of one gas-engine The question subsequently came before the Corporate Buildings Sub-Committee, and, as it was thought that the modern installation of engines and dynamos might be utilised by other branches of the Corporation service, it was agreed to delay the matter for a month to give the various departments an opportunity of notifying their wishes. There are two sets of dynamos in the Municipal Buildings, the first of which is rather antiquated and worked by gas-engines, while the second is of the best modern construction and worked by steam. The Town Council held a special meeting on Tuesday last to consider the report of the Tramways Sub Committee upon the subject of tramway traction. Alderman Firth, the chairman of the Highways Committee, said the Council had to decide the kind of haulage which should be adopted in the future. He thought there would be no two opinions that there was no more inhumane kind of tramway traction than horse haulage; and the committee had come to the conclusion that horses should be abolished as far as Leeds was concerned. As to steam haulage, the committee considered that it ought not to be tolerated longer than reasonable Then came the question of motors worked by oil, but after carefully examining this system, which was only in an experimental stage, the committee felt that it would not do for Leeds to have an experimental scheme. Another kind of haulage suggested was that of motors worked by gas but this, too, the committee unanimously felt would not do, as it could not be claimed for it that it had been a success up to the present time. The only two systems left for them to consider, therefore, were the cable system and electricity. It must be patent to everybody who had given the smallest consideration to the question that both systems could not be adopted, as it was necessary to have through communication from one part of the city to another without any change of tramcars. The committee had no alternative but to choose between these two systems. In the case of the cable system, the initial cost would be £428,922, and the working cost would be £101,819. The initial cost of the electric system would be £378,499, and the annual working cost £90,072. These figures, compared with the estimates of the cable system, showed a saving of £50,423 in the initial cost, and of £11,747 in the annual working. In the opinion of the majority of the members of the committee the electric system beat the cable hollow. In the cable system three-fourths of the power generated had to be used to work the cable itself, even if there was not a single car upon it, whereas with electric traction practically all the power generated was usable. After enumerating other advantages of the electric system, Alderman Firth remarked that the residents in Roundhay-road complained very much about the electric poles and wires at the time of their erection, but now they scarcely found an inhabitant of that district who would consent to their demolition and to the abolition of the tramways. One difficulty could be surmounted by the power which was being sought in a parliamentary Bill to erect the electric poles on the face of the buildings The Tramways Committee were all but unanimous and the Highways Committee nearly unanimous, not entirely, on this question There was a very large majority in favour of the adoption of the electric system. He moved and Alderman Scupham seconded, the adoption of the committee's report. Mr. Hannam moved an amendment that the question be referred to the committee for further consideration He did not think that the citizens of Leeds contemplated that they should disfigure the city by introducing the system of overhead wires in connection with electricity. As to electric haulage, he believed that the self containing accumulator system would be very much improved in the near future and largely adopted. A twelvemonth to await developments might be a matter of great advantage. Mr. Leuty, M.P., said, although he supported the proposition, he did not wish the Council to commit itself to putting down all the miles of conduit system mentioned in the report The Council then debated the question for about five hours, the objections raised being not so much to the principle of electric traction as to the system to be adopted. Ultimately, on the understanding that the committee would experiment with a short length of the conduit system connected with the overhead system, the original motion was carried by 40 votes against 11.

PROVISIONAL PATENTS, 1895.

OCTOBER 1.

18318. **Improvements in hanger-boards for electric arc lamps.** Thomas Edgar Adams 18, Buckingham street, Strand, London. (Complete specification.)

OCTOBER 2.

18376. **Improvements in holders for incandescent electric lamps** William Matthew Hart and William Henry Whiteside 2 Market street, Bradford.

18385. **Duplex telephony** Abner Mulholland Rosebrugh, 107, Mutual street, Toronto, Canada.

18406. **Mode of producing contemporary hypochlorites, chlorates, hydrochloric acid, caustic soda, and hydrogen from the sea-water by means of the electricity.** Giovanni B. Baldo, 16 Via Stadion, Trieste, Austria (Complete specification.)

18420. **Improvements in electrical apparatus for railway signalling.** Alfred Horatio Sisson Daniell, 1, Queen Victoria-street, London.

OCTOBER 3.

18440. **Improvements in arc lamps.** George Hill, 17, St. Ann's-square, Manchester.

18453. **Electric cable casings.** George Hinde Nisbett, 8, Quality-court, Chancery-lane, London.

18483. **Improvements in electric glow lamps.** George Davis, 246, Vauxhall Bridge-road, London.

Digitized by Google

18484. **Improvements in safety devices or fuses for electric circuits.** Arthur Marston Billington, 46, Lincoln's-inn-fields, London.

18505. **A new or improved method of and apparatus for electrically transmitting indications or changes of position of a body.** Harry Otto Ferdinand Bindemann, Norfolk House, Norfolk-street, London. (Complete specification.)

OCTOBER 4.

18531. **Improvements in recording instruments for telegraphic and other purposes.** William Thomson, Baron Kelvin, 154, St. Vincent-street, Glasgow.

18557. **Improvements in galvanic and storage batteries.** Joseph Baxeres Torres, 17, St. Anne's-court, Wardour-street, London.

18583. **Improvements in means for making electric connection between lengths of rail and the like.** Henry Edmunds, 47, Lincoln's-inn fields, London.

18584. **Improvements in or connected with electrical conductors.** Henry Edmunds, 47, Lincoln's inn fields, London.

18586. **An improvement in secondary batteries or accumulators.** Richard Pearson 53, Chancery lane, London.

18588. **Improvements in fusible cut-out or safety devices for electric conductors.** Gerald William Partridge and Arthur Francis Berry, 46, Lincoln's-inn-fields London.

OCTOBER 5.

18602. **Improvements in electric light and tail lamps for omnibuses, tramcars, and other road vehicles.** Henry William Headland, 77, Chancery-lane, London.

18622. **Improvements in commutator brushes.** Nathaniel Greening and N. Greening and Sons, Limited, 70, Market-street, Manchester.

18632. **Improvements in holders for incandescence electric lamps.** Charles Mark Dorman and Reginald Arthur Smith, Ordsal Station Electrical Works, Salford, Manchester. (Complete specification.)

18673. **An automatic speed regulator for electromotors** Louis Denayrouze, 28, Southampton-buildings Chancery-lane, London.

18681. **Improvements in alternate-current distribution.** Galileo Ferraris and Riccardo Arno, 45, Southampton-buildings, Chancery lane, London.

18692. **Improvements in the construction of electrodes or plates for secondary batteries.** Frederick Edward Everard 59, Roden-street, Holloway London.

18696, 18697, 18698, 18699, 18700, 18701. **Improvements in or connected with electric railways or electric transport.** James Grieve Lorrain, Norfolk House, Norfolk street, London. (Frederick Carleton Esmond, United States.)

OCTOBER 7.

18725. **Improvements in electric cables.** George Hinde Nisbett, 8, Quality-court Chancery-lane, London.

18726. **Improvements in electric cables.** Joseph Arthur Lovel Dearlove and George Hinde Nisbett, 8, Quality-court, Chancery-lane, London.

18769. **Improvements in or relating to the transmission of electricity and sound, and a means of reducing electrical resistance in the air, earth or sea.** Richard Joseph Crowley, Mitre-court, Fleet street, London.

OCTOBER 8.

18822. **Improvements in mounting electric incandescence lamps for orchestral reading and like purposes.** William Crawshaw and Henry Bevis, 73, St. Stephen's-road, Upton Park, London.

18868. **Improvements in electric velocipedes.** Hosea Waite Libbey, 45, Southampton-buildings, Chancery-lane, London.

18870. **Improvements relating to electromotors and transformers.** Walter Langdon-Davies and the Alternate-Current Electromotor Syndicate, Limited, 24, Southampton-buildings, Chancery-lane, London.

18875. **Improvements in concentric electric cables.** Henry Edmunds, 47, Lincoln's-inn-fields, London.

OCTOBER 9.

18911. **Improvements in electrical hanging bell push.** Henry Benest, 15, Campbell-road, Bow, London.

18912. **Illuminated decoration by electric light in plaster ornaments.** Charles Gillard, High-street, Chard, Somerset.

18931. **Improvements in prepayment apparatus for attachment to gas, electricity, or other fluid meters.** Wesley Webber, 4, South-street, Finsbury, London. (Date applied for under Patents, etc., Act, 1883, Sec. 103, April 16, 1895, being date of application in United States.)

18935. **Improvements in apparatus employed in regulating electromotive force in alternating-current circuits for theatre-lighting or other useful purposes.** Isaac Probert and Ernest Francis Moy, 433, Strand, London.

18944. **An improved method of insulating electric conductors.** George Sutton and Robert James Hatton, 53, Chancery-lane, London.

OCTOBER 10.

19002. **An improved wheel trolley for single-wire system of electric traction.** Henry Brecknell, 64, Lawrence-hill, Bristol.

19027. **Improvements in electric metering apparatus.** William Lloyd Wise, 46, Lincoln's-inn-fields, London. (William S. Barstow, United States.)

19067. **Improvements in electric signalling apparatus.** Frank Warren, 40, Chancery-lane, London.

OCTOBER 11.

19104. **An improved method of making and applying electric rail-bonds.** Frank Edward Buxton, 5, John Dalton-street, Manchester. (Date applied for under Patents, etc, Act, 1883, Sec. 103, April 15, 1895, being date of application in United States.) (Complete specification.)

OCTOBER 12.

19177. **New or improved electric lantern for velocipedes.** H. Otto Johnsen, 7 Quality-court, Chancery-lane, London. (Complete specification.)

19199. **Improvements in dynamos.** Anthony George New and Arthur James Mayne 55, Chancery-lane, London.

19204. **Improvements relating to electric signalling in open circuits** Joseph Rayner Gibson, 45, Southampton-buildings, Chancery-lane, London. (Complete specification.)

SPECIFICATIONS PUBLISHED.

1894.

10426 * **Dynamo-electric machines.** Kingdon. (Amended specification.)

18172. **Extracting gold by electrolysis.** Maclean and Bull.

18427. **Electrical traction.** Hutin and Leblanc.

19668. **Arc lamps** Gomess.

20595 **Railway electrical signalling devices.** Grimes.

21366. **Electrically-propelled vehicles.** King.

22340. **Multipolar dynamo machines.** Addenbrooke.

1895.

9937. **Secondary batteries.** Hammacher.

12622 **Secondary or accumulator cells.** Müller.

13573 **Telephone switches.** Stock.

NOTES.

A Good Substitute for Guttapercha is said to be prepared as follows: Tar, one part; paraffin, 10 parts; dissolve together at 120deg., and then add caoutchouc, two parts. Keep at this temperature until a homogeneous mass results.

International Exhibition at Kiel.—From the end of May to the end of September, 1896, a naval and fisheries exhibition will be held in Kiel, in conjunction with an industrial exposition of the province of Schleswig-Holstein. It is proposed that electricity shall be well represented at the show. Particulars may be obtained from Herr Geh. Kommerzienrath Sartori, or Herr L. v. Bremen, in Kiel.

A Substitute for the Electric Bell.—What is called an electric trumpet, the invention of Captain Zigang, is described in *L'Etincelle Electrique* of October 20. It is proposed as an improvement on the ordinary electric bell. The mechanism closely resembles that of the latter, except that the hammer strikes on a thin metal plate mounted in a ring similarly to a telephone plate, and that the make and break is very much quicker. It is stated that the sound produced is musical, and the pitch can be altered by varying the pressure on the spring.

Conduction of Metallic Filings in a Dielectric. M. G. T. Lhuilier has been experimenting at the Prytanée Militaire on the conductivity of metallic filings contained in a dielectric. Copper, aluminium, and iron filings were tried with various dielectrics, both solid and liquid. The conclusion arrived at is that the dielectric in such cases never acts as a conductor. With dielectrics composed of organic substances, conductivity is established concurrently by the metallic particles in contact and by particles of carbon produced by the dissociation of the dielectric. With sulphur only the former occurs.

Cost of an Arc Lamp per Year.—Figures have been published in the States giving the "usual cost of operating and maintaining an arc lamp per annum." Four pounds of coal per hour for 12 hours would be required for every 2,000-c.p. lamp for 4,000 hours per year. In Albany this would cost 26·40dol. per year. Other items which are enumerated bring the cost of supplies to 58·40dol., to which are added labour, 29dol., and interest and depreciation, 43·33dol., making a total of 130·73dol. In 101 cities in the United States having all-night service the average annual charge is 150·72dol.

Trees and Lightning.—In a series of experiments made to ascertain why trees are so frequently struck by lightning, it was demonstrated that the green wood of pine trees is a bad conductor, and so much the worse in proportion as the tree is richer in oil. On the contrary, the green wood of such trees as are poor in oil conducts electricity relatively well. Living wood is a much better conductor than dead. The existence of dead branches in trees of both categories, therefore, increases the danger. Compare the note "Nature's Lightning Rods," in the *Electrical Engineer* of October 11, p. 409.

Calcium Carbide.—Herren Otto Mielke and Eduard Worringen discuss, in the *Elektrotechnischer Anzeiger* of October 20, the direct application of calcium carbide to electric lighting and incandescent lamps with calcium-carbide filaments. The light given by the latter is stated to be "surprisingly brilliant," and to be a colour between that of the arc lamp and the carbon-filament lamp; and the eyesight is not in the least affected by it. The calcium-carbide lamp, candle-power for candle-power, and voltage for voltage, is two-thirds of the size of the carbon lamp, and it is said to be equally adapted for indoor and outdoor illumination.

Electrically-Worked Turrets.—The President of the French Republic has recently visited the works of the Compagnie des Forges et Chantiers to inspect the Canet gun turrets ordered by the Danish Government. According to the *Semaine Electrique*, these present great facility in working. The loading and direction are done electrically, but the elevation is done by hand, as this is absolutely necessary for work at sea. There being no water under pressure, the danger of freezing is avoided. The tower is manipulated by a single handle, and if the operator is killed in action it continues its rotation to the point determined on, when the current is automatically cut off and the tower comes to rest.

The Addition of Lead to Copper.—The addition to copper of high conductivity of a small quantity of lead for increasing fluidity is the subject of a recent patent. It has been discovered that the addition of a certain proportion of pure lead, preferably from 0·5 to 1·5 per cent., detracts but very little from the conductivity of the metal, and, so far as experiments have been made, in a far less degree than the addition of either tin or zinc, which metals have hitherto generally been employed to improve the castings. It may be mentioned that this addition of lead has long been known to have this effect on gunmetal and brass. It has also been known that the addition of lead to molten cast iron has a similar effect and produces cleaner castings.

The Electrical Production of Metallic Mirrors forms the subject of a patent taken out by Herr Hans Boas, of Kiel. The method is based upon the by no means new observation that various metals—namely, those of high specific gravity, therefore particularly the precious metals—enclosed as electrodes in a Geissler tube or other vacuum vessel upon the passage of an electric discharge, for example, of a Ruhmkorff spark inductor or of a high-pressure direct or alternating current, in so far as they form the cathodes, are dissipated and deposited as metal or its oxygen combination on the walls of the vessel. If the tube or the holder be filled with an oxygen-free gas of low pressure, say, with hydrogen, the metal, it is stated, is compactly deposited in perfect purity on the vessel sides, and produces a mirror of a lustre such as is not to be obtained by any other method.

Norwegian Waterfalls.—The sale of cascades in Norway is developing into quite a commercial feature of that country, which is not otherwise very profitably endowed by Nature. One of our consuls in Norway, Vice-Consul Eyde, of Flekkefjord, reports: "The past year has shown eminent inclination for the purchase of waterfalls, and all our falls, both large and small, are already engaged by speculators. The waterfall Rafos, at the River Kyma, has been sold through Mr. Chr. Salvese, of Leith, to Herr Grätzel von Grätz, of Hanover, for a sum of £15,000. The fall is very large. An aluminium manufactory is said to be intended. The waterfall Struben, in the River Aaen Sire, is said to be sold for £8,300. Its intended use is not yet known." By the way, about 200 railway carriages are now lighted by electricity in Sweden, and in Denmark the same system is also in use on the better trains.

France and Submarine Cables.—Returning to the question of England's monopoly of the cable system (see p. 437, October 18), the *Débats* says that by geographical situation France should be the telegraphic centre of the world, and were the Government to take the matter resolutely in hand, Paris, in the course of time, would "outdistance everything as the general information office of the

Digitized by Google

universe." The terms of the agreement which the French Government proposes to conclude with the Compagnie Française des Cables Télégraphiques for the laying, working, and maintenance of a new cable between France, North America, and the Antilles have been issued. The company is to lay a direct cable from Brest to New York, to renew, if necessary, the existing Pouyer-Quertier cable, and to extend both to the Antilles by an independent line from New York to Puerto Plata. The cost of the new cable is estimated at 30,000,000f., and the Government will pay an annual subsidy of 800,000f., or $2\frac{2}{3}$ per cent. on the capital outlay, until the returns reach 1,650,000f., or $5\frac{1}{2}$ per cent., when the subsidy will be reduced. With such terms as these the French company ought, at least, to be above the necessity of cutting rates in future, and to avoid the unpleasant suspicion which at present attaches to it.

North-East Coast Institution of Engineers and Shipbuilders.—At the invitation of Alderman T. Richardson, M.P., president of this institution, and Mrs. Richardson, some 700 ladies and gentlemen were entertained last Friday evening at a conversazione held in the Assembly Rooms, Westgate-road, Newcastle. The invited guests included Mr. W. D. Cruddas, M.P., Mrs. and Miss Cruddas; Alderman Hamond, M.P., and Miss Hamond; Mr. F. Flannery, M.P., and Mrs. Flannery; Sir E. T. Gourley, M.P., the president of the Institution of Mechanical Engineers; the foreign Consuls of the district; the Sheriff of Newcastle, Mrs. Sanderson, and Miss Sanderson; Sir Raylton Dixon, Middlesbrough; Mr. and Mrs. Wilson Worsdell, the president of the Hull Institute of Naval Engineers and Architects; Mr. H. H. Wake, engineer to the Wear Commissioners; Mr. P. J. Messent, engineer to the Tyne Commissioners; Sir Benjamin and Lady Browne, Principal Gurney and the professors of the Durham College of Science; the Mayors of Middlesbrough, South Shields, Cork, Hartlepool, and Jarrow; Mr. F. C. Marshall, Mr. Wigham Richardson, Mr. Robert Thompson (ex-president), Mr. Theodore Doxford, M.P., etc. The rooms were beautifully decorated, and from 7.30 to 8.50 Mr. Amers's Royal Exhibition Band discoursed a programme of music, and later played for dancing from 9 o'clock till midnight.

Electric Traction.—The report of the committee on electric traction appointed by the Association amicale des Ingénieurs électriciens has been published in Bulletin No. 4 of the association. The committee consisted of MM. M. J. Laffargue, F. Eschwège, A. Hattu, A. Hirtz, J. Sarcia, and A. Vernes. The report is divided into two parts, the first dealing with mechanical traction in general and going into the cost, etc., of the various systems. The conclusion is that the advantage rests with electric traction, and that that method will be increasingly adopted in the future. In the second part the different systems of electric traction are considered. Under the head of carriages containing their own supply of energy, descriptions are given of the old accumulator tramcars run from the Madeleine to Levallois-Perret in 1890, and the present tramways from the Madeleine to Saint-Denis, and from the Opéra and Neuilly to Saint-Denis, as well as those at Birmingham, Mount Vernon (New York), the Hague, and Vienna. The Heilmann locomotive is also dealt with. In the cases where energy is exteriorly supplied, the report considers the overhead and underground trolley systems. Mountain and mining work is also dealt with and accounts added of lines erected. In view of the importance of canal traction, the experiments of M. Galliot on the Canal de Bourgogne in 1895, and of M. de Bovet, on the Canal de Saint-Denis in 1894 are mentioned. The report contains altogether much important information methodically classified.

The Calomel Electrode. — The *Journal* of the Chemical Society gives an abstract of a paper by Mr. G. W. Coggeshall on this subject. A number of calomel electrodes were prepared in order to test their values and constancy at different times. The first set of experiments gave from time to time undoubted deviations from a constant value, and the form was slightly altered by placing over the mercury a quantity of sand grains, by which the surface of the calomel was increased and the saturation of the solution more completely insured. With these cells it was found that the E.M.F. during 40 days did not deviate from the normal value by more than 0·0008 volt. Experiments were next performed to test whether the size of the mercury surface affected the constancy of the electrode, the results being in the negative. The time required for the E.M.F. to reach its constant value was in most cases from 30 hours to two days. The effect of slight impurities was found by the use of commercial calomel and mercury, and although the purity of the mercury is of considerable importance, the commercial calomel is only very slightly inferior to the pure compound. It is hence possible to obtain a number of electrodes giving similar results, and the constancy of ordinary calomel electrodes may be regarded as within about 0·001-0·002 volt. The temperature influence was also determined, and the E.M.F. found to increase with the temperature; the coefficient between 0deg. and 25deg. being 0·000678, and between 25deg. and 50deg., 0·000647 (volt per degree), whilst the E.M.F. reaches its value in a few hours after the increase of temperature. The absolute value found by Rothmund was 0·561, a number Mr. Coggeshall considers as probably correct.

Spectra of Argon and the Aurora Borealis.—M. Marcellin Berthelot has been experimenting with mixtures of argon and benzene vapour, and with a view to procuring a combination has submitted them to the action of the silent discharge. According to *Comptes Rendus*, under the particular conditions of the discharge known as "rain of fire," there is developed an intense greenish-yellow fluorescence, the spectrum of which shows lines and bands in the yellow, green, blue, and violet very similar to those observed in the spectrum of the aurora borealis. Some of the bands are crossed by black absorption lines, owing to the thickness of the fluorescent layer. It is suggested that the aurora borealis may be due to the production of a fluorescent modification or compound of argon under the influence of atmospheric electricity. M. Berthelot says that pure argon, when mixed with benzene vapour, and subjected to the action of the silent discharge, undergoes very little change of volume, and the condensation previously observed was probably due to the presence of nitrogen as an impurity. With a coil connected with a Leyden jar and giving a spark 10mm. to 12mm. in length, the mixture of argon and benzene vapour becomes luminous after a time ranging from 15 minutes to four or five hours. It has a violet tint with a reddish "rain of fire." After some time the fluorescence becomes much more brilliant, and the colour changes to a brilliant green, and finally to blue. When this point is reached the fluorescence will continue for several hours, but after a long time, especially if the intensity of the spark is increased, the fluorescence disappears, and only a very feeble luminosity remains. If at an earlier stage the discharge is interrupted the fluorescence at once disappears, but on again completing the circuit it reappears, either immediately, or after a time increasing with the time that has elapsed since the interruption of the discharge.

Electricity in Chemistry.—A new process for the manufacture of caustic soda and bleaching powder, which, it is claimed, must produce great changes in the conditions

Digitized by Google

under which the industry is at present carried on, is announced. It is the invention of Mr. Hamilton G. Castner, the chemist who brought out the method for the production of aluminium which was worked at Oldbury, near Birmingham, by the Aluminium Company, which controls the new system referred to. Hitherto caustic soda and bleaching powder, which are the chief products of the works in the United Alkali Company or Chemical Union, have been produced by the old Leblanc process, which is as old as the year 1791, but has since from time to time been improved. By this process, however, it is found difficult to produce caustic soda for less than £6 or bleaching powder for less than £5. 10s. per ton. The Castner method, it is said, reduces the cost of manufacturing caustic soda to £4. 5s. and of bleaching powder to about £3 per ton, so that it is apparently much more economical. But this is not all. The ordinary quality of caustic soda corresponds to what is technically known as 70 per cent. Liverpool test, whereas the soda produced by the Castner process is stated to answer to 78·5 per cent. Liverpool test. The fundamental feature of the new system is the employment of a moving body of mercury, which helps the electric action, forming an amalgam which is decomposed electrically as soon as it is formed. The cells employed are different from any hitherto suggested, and, it is stated, only one-fifth of the size used in any other process, actual or proposed. The great feature of the new method is said to be that it requires very little labour, being for the most part automatic. The Aluminium Company have been working the process experimentally at Oldbury for about a year, and, we understand, are now about to build large works in order to manufacture caustic and bleach.

Hysteresis.—In connection with an article on the law of hysteresis by Herr Chas. Proteus Steinmetz in the *Elektrotechnische Zeitschrift* of September 26, Herr Rob. M. Friese gives the following supplementary piece of information in the last number of that journal. It consists of three remarkable results obtained in the ordinary investigations in the iron-testing department of the Elektrizitäts A. G. vorm. Schuckert und Co. In the chemically almost identical specimens the values of η considerably differ. The Steinmetz formula is $H = \eta B^{1.6}$, where H is the loss of energy per cubic centimetre produced by hysteresis. Annexed are the results of the chemical examination of three ingot-iron plates, which came from various German works, together with the corresponding values of η:

	Plate I. (No. 297)	Plate II. (No. 245)	Plate III. (No. 278)
$\eta \cdot 10^3$	1·62	1·81	4·30
	per cent.	per cent.	per cent.
Total foreign substances	0 4473	0 3332	0 9035
Carbon	0·0967	0·2074	0 2906
Graphite	0·0096	0·0076	0 0113
Sulphur	0 0732	0 0160	0·0985
Silicon	0·0020	0·0230	0·0112
Copper	0·1776	0·0310	0·1003
Lead	Trace	—	Trace
Zinc	Min. trace	0·0032	Min. trace
Manganese	0·0395	Trace	0·3610
Nickel	0·0487	—	Trace
Calcium	Trace	0·0450	0 0306
Aluminium	Not referable	Trace	Not referable
Phosphorus	„	Not referable	„
Arsenic	„	„	„

The smallest value for $\eta \cdot 10^3$ hitherto observed at Schuckert's was 1·38. This was plate No. 115, from a Swedish ironworks. The greatest value for $\eta \cdot 10^3$ was possessed by plate No. 77, from a German ironworks, with 6·94.

Electricity in Gold and Silver Mining.—A recent article on the application of electricity to gold dredging illustrates another of the numerous applications of electricity. In this case, on account of the high price of fuel, the wealth known to exist could scarcely have been realised by any other means, and in no event with anything like the same convenience. The gold and silver mining regions, a Transatlantic contemporary remarks, furnish ideal conditions for the use of electrical power, and we may expect vast extensions of such use as the success of pioneer installations becomes plainly evident, particularly of those employing polyphase systems. In probably few mining districts is there any lack of water power within a reasonable distance, and where the system of mining requires any considerable quantity of power, electricity is the obvious source and by far the most convenient agent, from its ease of application to all manner of work. Owing to the conditions in many places, the pole line is a weak point where the power has to be transmitted a considerable distance, but this can be overcome by cheaply installed systems of underground transmission, which, however, do not always seem to have been considered. In Europe it has been found that cables simply buried in a trench over a porous bed (sand always being used there as the bed) give better results than the most elaborate conduit system, and the same method could, of course, be applied in many cases in mining regions where a long pole line would introduce an element of unreliability during certain seasons. Owing to the great amount of thought now being devoted to the subject of electrometallurgy, it may be that methods will be devised whereby precious metals will in most cases be directly extracted by electricity from ores as they come from the mines, or at least the valuable minerals so concentrated as to greatly reduce carriage costs. At present the electrical method of refining from concentrated products reduced by heat is in large use, and if the first step could also be accomplished by electrical means enormous savings in shipment charges would be effected. With the great water powers existing in the mining regions of the Far West, and the absence of cheap fuel, the field for the employment of electrical energy there is one which should result in vast developments.

Supposed Faults of Multiphase Systems.—In a paper read at the Ottawa Convention of the Canadian Electrical Association on "Some Modern Alternating-Current Apparatus," it is stated that multiphase systems are subject to the serious disadvantage that the circuits must be kept balanced. As the author follows up the statement by advocating in fulsome terms a competing system which is declared to have all the advantages of all other alternating systems and none of their disadvantages, his point of view can scarcely be considered disinterested, but is none the less mischievous. Through like statements made on similar occasions, the *Electrical World* of New York says, an impression has been created and widely extended that multiphase systems are impracticable for general use, for the reason that their several circuits will not admit of being unbalanced. While it is true that theoretically perfect conditions are only attained when such circuits are in balance, it is also true that multiphase systems will operate entirely satisfactorily within the limits that are likely to exist with respect to balance in any practical installation. We will add that we make this statement on the best of authority, and it is, moreover, upheld by the verdict of practice. At the Cleveland Convention of the National Electric Light Association, a central-station man operating a two-phase system said that no trouble had been experienced when one of the two circuits—each of which carried

Digitized by Google

both light and power—had a load 50 per cent. greater than the other. At an exhibition of a two-phase system, several months ago, the circuits were so arranged that the loads could be unbalanced 20 per cent., and no effect on the lights was noticeable when such a change was made. It is in one respect unfortunate that the phenomena of alternating currents have become well known, for the general knowledge now possessed with respect to them is apt to be misapplied, to the detriment of the industry. If in the days when the simple alternating current was first introduced the phenomena of inductance and hysteresis had been well known, the growth of the alternating-current industry would probably have been seriously retarded, for how wisely would it have been argued that, in competition with the system then in use, there would not be a ghost of a chance for one whose regulation was handicapped by both inductance and transformer drop. Not being withheld by the existence of such doubts, the alternating people went ahead and produced results that were satisfactory from a practical standpoint. Even at the present day a theoretical consideration of the disadvantages of the simple alternating system with respect to regulation is likely to raise doubts which, however, are as soon dispelled by a remembrance of the fact that, grave as the objections may seem to be, they have no weight in practical working.

Indiarubber.—In the August number of the *Bulletin de la Société d'Encouragement* M. Chapel has an article on the progress of the indiarubber industry, which has been the consequence of a continually increasing demand for this substance. The most important source of indiarubber supply is Brazil, and the annual production of the best-quality rubber derived from that country, and known as Pará, has risen from less than 17,000 tons in 1889 to rather more than 20,000 tons for the year 1894. America also sends to the market the sorts known as Pernambuco, Ceara Scraps, Peru, Guatemala, etc., but the importance of these consignments shows considerable variation, and these qualities of rubber have a tendency to disappear. The supply from Africa has been largely influenced by the work of explorers during the last 20 years, but it is principally from the Congo basin that new varieties of rubber have reached us, coming down both to the West Coast and to factories on the shores of the Indian Ocean. From the West Coast we get Kassai and the little black balls with a white centre known as African-Equator. It must be remembered that among these new sorts there are several which have nearly the same character as rubbers that we used to receive under different names. From the Congo district come also Lopori, Congo cakes which are nothing else than what were formerly called Congo balls made up in a different shape, and also Red Kassai, which has a very strong resemblance to Loanda prima. Under the name of Upper Congo there also reaches us from the West Coast a rubber that was formerly known as Mozambique. Madagascar rubbers have received an addition under the name of Madagascar Niggers. This is a good rubber, in quality resembling Loanda, but having the horny appearance of Ceara Scraps. It, however, contains much earth. Nothing certain is known of its botanical origin. From New Zealand have come some packages of a rubber which appears very elastic, but which does not bear cutting up well. It is the produce of the banyan (*ficus religiosa*), and the rapidity and facility with which this tree reproduces itself may make it important in view of the wasteful methods adopted by the natives, who in many places practically destroy the tree to obtain the rubber. After urging the desirability of further trials of the *manihot glaziovii*, M. Chapel turns to the improvemen and economy in the manufacture that has been effected by the adoption of larger rollers. It is at present impossible to completely eliminate the sulphur contained in vulcanised indiarubber, and all processes for the remanufacture of old rubber are more or less unsatisfactory. Nevertheless, in spite of the continually increasing demand, the tendency is to seek a good appearance and a low price rather than to produce an article that shall have the solidity and durability of the old-fashioned indiarubber. Again, from another source, we learn that the newly-developed production of indiarubber in Lagos promises soon to attain important dimensions. In 1893 no imports of this article were recorded as received from the colony, and last year the amount was only £5,994. By a single steamer which left Lagos at the beginning of last month, however, the value of the indiarubber shipped to Liverpool was £15,000. The new industry appears to have given rise at Lagos to some excitement resembling that which is often occasioned by a new gold discovery. Numbers of clerks, small traders, and others, including, it is said, even professional men, have gone into the interior to profit by the collection and manufacture of the gum. The native owners of the forests are, however, insisting upon the payment of royalties, and some of them are themselves entering into the business of preparing the rubber for the market. Prices in the interior have been considerably advanced, and there is no longer so much profit as there was at first in purchasing and transporting it to the coast. Some fear is expressed that the ordinary trade in palm oil and palm kernels may suffer from the diversion of labour to the fresh industry, and that the supply even of indiarubber itself may be threatened by the indiscriminate tapping of immature trees. It is suggested that the Colonial Government should take steps to prevent the spread of the last-named evil.

The Berliner Telephone Cases.—A writer in *Electricity* of New York has carefully investigated the points involved in the Berliner disputes, and his elucidatory remarks on the subject may be interesting to readers on this side. He says: There are really two Berliner cases now occupying the attention of the telephone world. The first has reached the third and final stage, and had its origin in the bill in equity filed by the Attorney-General of the United States against the Bell Company on February 9, 1893, in which it was alleged that the Berliner transmitter patent of November 17, 1891, was an illegal grant and it ought of right to be annulled. The decision of Judge Carpenter of the Circuit Court of the Massachusetts district and the subsequent reversal by the Circuit Court of Appeals are of too recent occurrence to require further mention. A few weeks ago the decision of the Court of Appeals was appealed to the Supreme Court of the United States. The case has been docketed at Washington to be heard in the regular course. To rightly understand the situation, it must be borne in mind that the decisions already rendered in the Government suit on the Berliner patent have not determined the validity of the patent. The reversal of Judge Carpenter simply rehabilitates the patent, leaving it on an equal footing, before the law, with any other patent owned or controlled by the Bell Company, or by anyone else. The second and more important of the Berliner cases is the suit of the Bell Company for an order to restrain the National Telephone Manufacturing Company, the Bay State Telephone Company, and the Century Telephone Company of Boston from alleged infringement of the Berliner 1891 patent. The bill of complaint was filed on August 6. At the hearing assigned for September 3, 30 days were given in which to file an answer to the bill of complaint. At the expiration of this time, on the

Digitized by Google

3rd inst., an order was issued extending the time for filing answer until October 15. The granting of an injunction in the Boston cases will, of course, affect directly and immediately only those companies against whom action is brought, but it is to be presumed—in fact, is so declared by the Bell Company—that similar action will be taken against not only other alleged infringers in the Massachusetts judicial district, but wherever found. The Berliner patent alone, if valid, practically controls commercial telephony so far as it is dependent upon microphones operating upon the constant-contact principle. We have always maintained, however, and still maintain, that commercial telephony is not dependent upon anything contained in the Berliner claims. The Bell Company have educated the public to believe that this patent is necessarily the sole key to the situation, but in our opinion this is a sheer fallacy. A new telephone exchange company, to be safe, however, should procure their apparatus of those manufacturers who are not only able but willing to guarantee their customers absolute immunity from damages for infringement of patents. The chief hope for the independent manufacturing companies lies in the defeat of the Berliner patent, because if that patent is out of the way the open field is much broader. Its validity can be successfully attacked in a properly prepared and conducted case. It is eminently desirable to the public that the Berliner patent should be defeated, but the sole recourse of the independent companies does not lie in its defeat. The old magneto instrument, the patent for which expired with the original Bell telephone patents, makes a far better transmitter than most people are aware. Good and distinct articulation has been given with this instrument over grounded circuits between New York and Cleveland and between New York and Chicago. If specially wound for long-distance transmission, its service over these distances could doubtless be far improved, and on metallic circuits be made even better than with transmitters of the variable-pressure type, as it already is for short distances. The public have been too willing to believe the dictum of the Bell Company that the variable-pressure microphone gives them the monopoly of the business or even gives them the best instrument. Even if the Berliner patent is sustained, the independents should not lie down, but should set their ingenuity to work to improve transmitters on the magneto principle until they attain an instrument that is in every way better than any now made on the principles covered by the patent in suit. Judged by the length of time other cases have been awaiting disposition by the Supreme Court, the writer concludes, it may be two years before a decision is rendered. American courts of law are notorious for their protractions and delays.

The Electric Annealing of Armour Plates.—The application of electricity in the annealing of armour plates is discussed by Mr. W. W. Hanscom, chief electrical engineer of the Union Ironworks of San Francisco. The nickel-steel armour plates, as furnished to the later vessels of the United States Navy, are by the Harvey process hardened on the face to a depth varying from ½in. to ¾in. This face is such that it successfully resists the hardest steel drill that can be made, and, as it is required in the final location of the plate to drill and tap numerous holes in it, it was necessary during the hardening process to protect the desired places by preventing the carbonising material from coming in contact with them. The operation was not entirely successful, however, as it was found upon trial that, although a number of the plates were sufficiently soft to be worked, others immediately alongside were as hard as the unprotected portions. A number of attempts were made to locally anneal these hard spots by means of the oxyhydrogen blowpipe and other apparatus, the most successful being that offered by the Thomson Electric Welding Company, of Lynn, Mass. It was found impossible by other means than electricity to apply sufficient heat in a concentrated form to attain the desired results, as the large mass of metal surrounding conveyed the heat away as fast as it was supplied. An annealing equipment has recently been installed at the Union Ironworks for annealing the armour plates of the battleship "Oregon." The apparatus in general consists of an alternator, with its exciter, a rheostat, a transformer annealer, and the engine for driving the same. The engine develops, at 450 revolutions per minute, 55 h.p. The alternator and exciter are of the ordinary commercial type; the former, of 40 kilowatts capacity, has six coils on as many pole-pieces, the windings being in two series of three in multiple. The armature is of the toothed type, with six coils, connected in a multiple of three series of two. It is wound for an output of 135 amperes at 300 volts when making 1,000 revolutions per minute. A pulley on the end of the armature shaft drives the exciter, a D-type shunt-wound generator of 110 volts at 2,000 revolutions per minute. Its terminals are connected to alternator fields through the regulating rheostat, a cylindrical frame, having German-silver coils cut into or out of circuit by a contact-arm on top. The coils are protected from mechanical injury by the wire-gauze covering, which arrangement permits of a constant circulation of air. The transformer annealer is of the shell type, and consists of an outer core of laminated iron surrounding both primary and secondary coils, the former being wound on a form and encased inside the latter, which is a hollow copper casting made in halves to receive it, and then bolted together, after which the remaining space is filled with oil for insulation and as an assistance in conducting away the heat generated in the primary. The secondary coil has but a single turn, U-shaped, to the ends of which are bolted various-shaped copper contact-pieces, which are hollowed and connected to a water circulation, thus preventing the heat of annealing from reaching the coils. The yoke from which the transformer is suspended by two trunnions, as well as the before-mentioned contact-pieces, permit of the transformer being swung into any desired angle and brought against any part of plates already located. In the operation of annealing the contact-pieces are brought up against the brightened surface of the plate and wedged into position, straddling the spot to be annealed, after the rheostat has been adjusted to a point reducing the primary current to a minimum. When the contact is established between the contact-pieces and the plate a slight humming noise notifies the operator, and the primary current is gradually raised to its maximum. A bright-red spot then appears under each contact-piece. The intense local heat at these spots causes the plate to expand outwardly in the direction of least resistance, forming slight mounds, from which circles of a gradually changing colour slowly approach the centre. The primary is kept up until the plate has become sufficiently heated to char or even ignite a pine stick held against it, and is then gradually decreased until it has again reached the minimum. The first or heating period requires about three minutes, during which the secondary current has reached from 3,500 to 6,000 amperes at four volts. The second or cooling period requires from 10 to 12 minutes, in order to prevent the sudden chilling of the spot due to the surrounding mass of metal and to ensure a perfect anneal. The plate at the spot of annealing presents a dark-blue colour, elliptical in shape, with a major axis of 4in. and a minor axis of 2½in., and is very readily drilled and tapped.

THE ELECTRIC LIGHT STATION OF THE EMPIRE OF INDIA EXHIBITION.

RECEPTION OF ENGINEERS BY MR. JAMES N. PAXMAN ON OCTOBER 23, 1895.

A contract for the supply of power to this installation was at the end of last year awarded by the London Exhibitions Company to Messrs. Davey, Paxman, and Co., of Colchester.

The lighting of the grounds and of the various buildings comprised in the Empire of India Exhibition, which was arranged by, and is under the charge of, Mr. Guy C. Fricker, calls for some 260 arc and 800 incandescent lamps, and, seeing that the installation is for a number of years, it has assumed quite the character of a small "central station." The exigencies of the case, however, call for two systems of driving, so that a part of the station is devoted to a belt-driven plant, and part to direct-coupled high-speed engine plant. Altogether there are eight belt-driven dynamos, all of the Brush Electrical Engineering Company's manufacture, but of various descriptions—viz., one 75-kilowatt Mordey alternator, five 55-light Brush arc machines, one 40-kilowatt low-tension machine, one 20-kilowatt low-tension machine. These are driven by two compound engines of Messrs. Davey, Paxman, and Co.'s well-known "Colchester" type, capable of developing 250 h.p. and 120 h.p. respectively, and one of their compound coupled girder engines capable of developing 120 h.p. All these engines are fitted with Paxman's patent automatic expansion gear. This plant is evidently doing excellent work. The engines, however, are so well known that no detailed description of them is necessary.

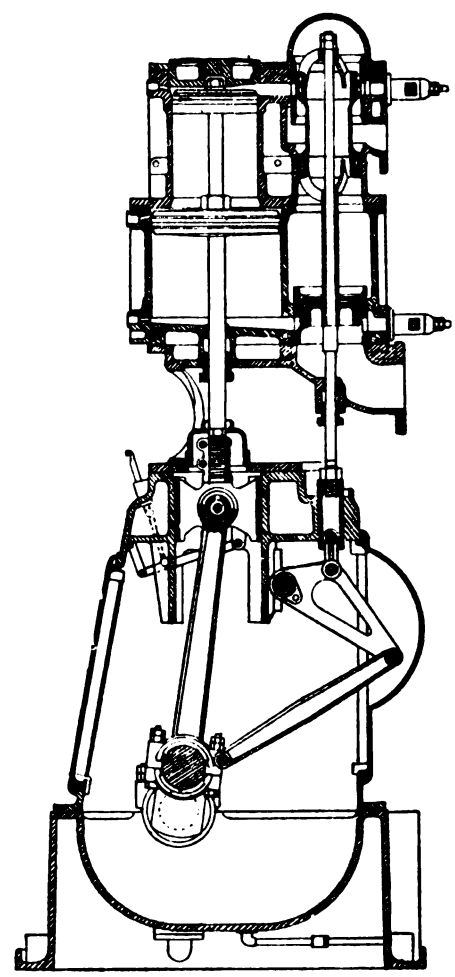
The chief interest centres in the high-speed single-acting engines, which are a new departure in Messrs. Davey, Paxman, and Co.'s practice. These are Peache's patent high-speed compound engines, two of which are three-crank engines, with three sets of compound cylinders 10in. diameter and 15in. diameter by 10in. stroke, arranged tandem over each crank. Each engine is coupled direct to a 100 kilowatt Mordey alternator, and runs at 325 revolutions per minute, developing about 220 h.p. each. The third is an engine with cylinders of the same size, but with two cranks only, set at an angle of 180deg., coupled direct to a 75-kilowatt Mordey alternator, running at 355 revolutions per minute, and developing about 150 h.p.

The engines run very silently, and there is no vibration perceptible. The governing is very close, being within 2 per cent. from full to no load, and yet there is no unsteadiness or tendency to "hunt." This is especially noticeable in the two-crank engine coupled to the 75-kilowatt alternator, which supplies the Empress Theatre lighting. In the exigencies of the theatre lighting, 90 h.p. to 100 h.p. is during the evening thrown off and on, often being nearly the whole load on the engine at the time, but the governor handles this with the greatest promptness and without any perceptible change in the speed of the engines. A further description of these engines will be interesting.

The first of these engines were started in January of the present year, and since then the three engines for the exhibition have been made and were set to work with the opening of the exhibition in June. These engines have proved themselves to be thoroughly satisfactory in every respect, and embodying, as they do, some novel features of great practical importance, together with thoroughly sound mechanical construction, they deserve the attention of those interested in the direct driving of dynamos and other high-speed machinery.

Referring to the sectional view given herewith, it will be seen that the high and low pressure cylinders are arranged tandem over the crankshaft. The crankshaft, instead of being placed in line with the cylinders, as usual, is placed out of line to the extent of the throw of the cranks. In a single-acting engine this is the right position for the crankshaft, for the crosshead slide is thus rendered single acting, and, moreover, the pressure on it is relieved; for during the down stroke, when the pressures are heaviest, the connecting rod is straight or inclined at a small angle, while on the up stroke, when the angle of the connecting rod is considerable, the pressures passing through the crosshead are at a minimum. In addition to the above reasons for justifying the unusual position of the crankshaft in the present case, it enables a very simple form of valve gear to be adopted, doing away with eccentrics, and thus giving room for large and compact bearings.

The distribution of steam in the engine is effected by a line of piston valves. Steam is admitted under the high-pressure valve to the top of the low-pressure piston, thence it is exhausted over the top of the high-pressure valve and through the centre of that valve to the receiver space. From there, it is admitted over the top of the low-pressure valve to the underside of the low-pressure piston, and finally under the low-pressure valve to the exhaust. The holding down of the line of pistons on the up stroke is effected by the compression of steam in the space between the high-pressure and the low-pressure cylinders, called the controlling cylinder; this steam is again expanded on the down stroke.



Sectional View of Peache's Engine.

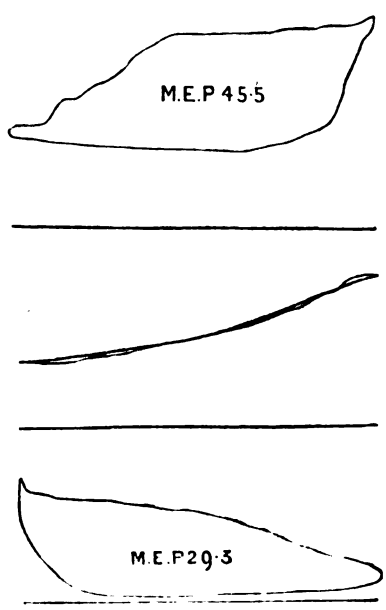
A very small by-pass port is provided, which is uncovered by the high-pressure piston at the top of its stroke, and which for an instant forms a communication between the top and the bottom of the high-pressure piston. This provides for the supply of any fresh steam which may be needed to maintain the supply of steam in the controlling cylinder, and here attention must be called to an important feature in the provision of the holding-down power, and one which is peculiar to this engine. The controlling cylinder diagram can be arranged so that it expands below the pressure of the steam in the low-pressure cylinder, and, consequently, on the first half of the up stroke, instead of the inertia of the reciprocating parts having to be overcome by power transmitted through the crankshaft, as is the case in other single-acting engines, it is overcome by the excess power developed on the underside of the low-pressure piston. The effect on strains in the crankshaft and friction on bearings is apparent.

It may be said that steam being used in the controlling cylinder must mean loss from condensation, but the position of the controlling cylinder in this engine must be remem-

Digitized by Google

bered—viz., between the high-pressure and low-pressure cylinders; and it is contended with reason that any heat passing from the steam in this cylinder does good work in heating up the walls for the following steam stroke in the high-pressure and low-pressure cylinders; and, in fact, with superheated steam or with superheating coils in the controlling cylinder, it is contemplated that the controlling cylinder may become the most efficient "steam-jacket" possible—viz., one that heats up the working surfaces in the working cylinders. The valves are shown arranged to be held down by the receiver pressure steam, and usually this is satisfactory, but, in cases that require it, a modification of the controlling cylinder can be applied.

The diagrams are reproduced from one set of a number taken from the first engine built during a six hours' steam trial at Colchester on July 26, 1895. The engine was run on the brake, and gave a consumption of 22lb. of steam per indicated horse-power, 88 per cent. of the indicated horse-power being measured on the brake. The boiler pressure available was 130lb.; there were sundry small leaks, and the steam was taken direct from the boiler to the engine without a separator being interposed, so that no doubt the engine did not get all the feed water that was debited to it as steam. The engine, too, was arranged as it would be in practice—viz., with a cut-off sufficiently late to give high M.E.P. (49·8lb. in this case with 130lb. boiler pressure), and not with a comparatively early cut-off—so



Diagrams taken from Peache's Engine

as to give a specially low steam consumption per indicated horse-power. These diagrams have been reproduced, therefore, not as a measure of the efficiency of the engine; but to give an idea of its working.

Special attention has been given to sound mechanical construction. The crankshaft, as it should be in a single-acting engine, has been made of ample strength—viz., one-third the diameter of the low-pressure cylinder. All bearings are very ample, and all parts are simple and strong. Consequently the engine will stand readily any pressure that can be brought to bear on it, whether for short or long runs. Every part is as easily accessible for examination or removal, as in an ordinary double-acting engine. There are no internal glands, and of the two external glands, one is exposed to the steam in the low-pressure cylinder only and the other to exhaust pressure steam only.

The advantages of the three-crank type of engines are so great, both on account of absence of vibration and evenness of turning, that Messrs. Paxman have adopted that as their standard type of engine.

The plant has been put down without allowance for spares, and during the evening all the engines are loaded; the confidence thus displayed by the London Exhibitions Company in their contractors—Messrs. Davey, Paxman, and Co.—being justified, for there has been no failure or hitch with the running of any of the engines.

Steam is supplied by a battery of nine of Messrs. Davey, Paxman, and Co.'s locomotive-type boilers, each having 710 square feet of heating surface and 19½ square feet of grate area, and each being easily capable of supplying steam sufficient for 120 h.p. The flanging of the steel plates by the very complete hydraulic plant at Messrs. Davey, Paxman, and Co.'s works, Colchester, is excellent, and, generally, the boilers are a fine example of boiler work.

A large number of guests sat down to dinner, which was well served by Messrs. Spiers and Pond. Only one toast was permitted, and that was proposed by Sir F. Bramwell, "Our Host." This was drank upstanding, and after a few words of reply the guests adjourned to the Empire of India Theatre to witness the spectacular performance under the direction of Mr. Kiralfy.

MUNICIPAL ELECTRIC LIGHTING ACCOUNTS.

At the meeting of the Association of Municipal Corporations held last Friday at the Westminster Palace Hotel, S.W., Sir Albert Rollit presiding,

The Town Clerk of Southport moved, "That a request be addressed to the Board of Trade from this association to promote a Bill in Parliament for the purpose of amending Section 9 of the Electric Lighting Act, 1882, so as to provide that the annual statement of accounts therein referred to should be made up to March 25 instead of December 31." The mover said that the object of the resolution was simply to provide that the electric lighting accounts should be made up to the same date as the other accounts instead of to a different date. It had been suggested that March 31 would be a better date than the 25th.

The Town Clerk of Wolverhampton seconded the resolution. He understood that the Board of Trade would be quite willing to take the matter into consideration. With regard to the form of the resolution, as it was a difficult affair when once a date was fixed by Act of Parliament to get it altered, he would suggest that the resolution should be "to such a date as the council may fix with the approval of the Board."

The resolution having been amended to this effect was carried unanimously without further debate.

DEY-GRISWOLD HYDRAULIC GEAR.*

Much thought has been expended in attempting to devise some form of gearing of electric railway motors that will enable the motor to run continuously and prevent the great waste of energy which now takes place in starting a car. The actual horse-power expended in starting a car is not large. While the horizontal effort is great the speed is low, and as horse-power is speed multiplied by horizontal effort the horse-power is low. The object then has been to devise a gear which will allow the motor to run at full speed and make use of all its available horse-power in the process of starting. The useful horse-power exerted by an electric motor in starting a car is only a small fraction of the energy that is consumed by it in so starting. The balance is wasted in heating motors and resistance. Various forms of gearing have been proposed to overcome this. The electrical method devised by H. Ward Leonard several years ago accomplished the end, but the apparatus necessary added so much to the cost, weight, and complication of the machinery on a car that it has never found favour.

Harry E. Dey, of the Dey-Griswold Company, has attacked the problem with a hydraulic gear. The motor is put in the centre of the truck, and drives a set of pumps filled with oil, which is piped to fluid motors on each axle, and so drives the car. The motion of the car is therefore dependent on the motion of the pumps, and it is manifest that when the pumps are operated with a very short stroke (although at constant speed) an immense effort can be exerted at a slow car speed as in starting, while for higher speed and less horizontal effort the stroke of the pumps can be increased. The most essential element of

* From the *Street Railway Review*.

Digitized by Google

the whole arrangement is, therefore, the variable-throw crank, which connects motors to pumps. These pump cranks are on the motor axle, and can be given any stroke from zero to 3in.

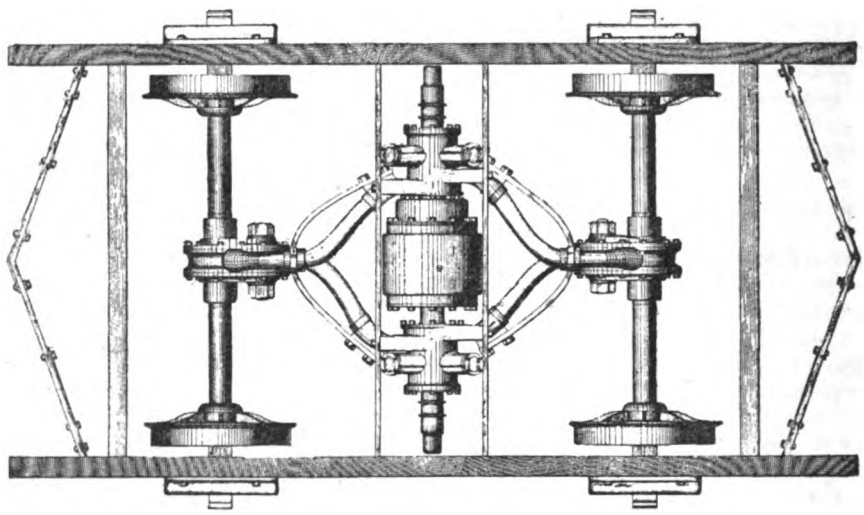


FIG. 1.

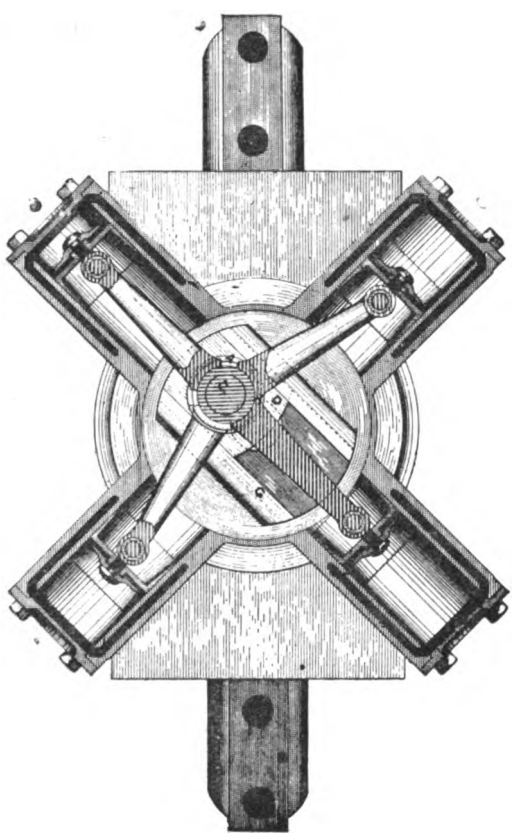

FIG. 2.

A general plan of the motor and hydraulic gear is shown in Fig. 1. Fig. 2 is a section through the pumps, and Fig. 3 a section through the fluid motor on the car axle. Fig. 4 is a section through the motor and pumps, and is the most interesting part of the apparatus. It will be seen that it is somewhat complicated. Both motor and armature revolve. The armature is connected to one pump, and the fields to the other. This gives a high inductor velocity to the armature with one-half the pump speed otherwise required. The fields are internal, and the brushes bear on the end of the commutator to avoid the action of centrifugal force. The length of the stroke of the crank is regulated by the motorman as follows: The crank, D E, slides in the dovetailed pieces, F G, which are fixed on the revolving axle. The crank has a rack meshing in the pinion, H. This pinion is keyed to the shaft, I, which has four high-pitch threads cut on it. The nut J threads on these, and also slides in a groove in K, which is an extension of the main shaft with which all of these parts revolve. A normally stationary nut, L, threaded on the outside has the nut J freely revolving inside of it, and kept in position by the collar shown. Working over the thread of the nut L is the sprocket nut N worked by a chain from the front platform.

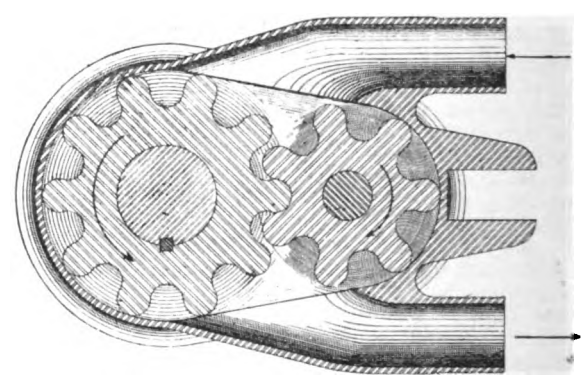

FIG. 3.

The motor is shunt wound, running at practically constant speed. When the car is to be stopped, the reverse process takes place from that when the car is started. The stroke of the pumps is shortened by the motorman and the fluid motors on the axles drive the pumps and

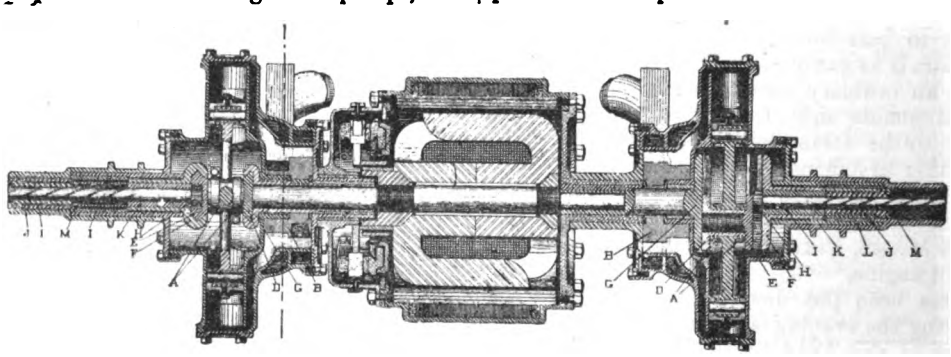

FIG. 4.

Digitized by Google

increase the speed of the motor. As it is shunt wound, it gives back energy to the line and acts as an electric brake. This not only is useful in making stops, but returns energy to the line when going down hill. The motor need not be as large as the usual series motor, because it never has to do more work than required when the car is at full speed. The controller and rheostats are done away with. The Dey-Griswold Company, of which the inventor is president has recently been incorporated to do a general electrical manufacturing business.

THE ELECTRIC LIGHTING OF EDINBURGH.

BY HENRY R. J. BURSTALL.

The following paper was read at the Institution of Mechanical Engineers on October 23, Prof. A. B. W. Kennedy (president) in the chair.

The electric lighting of Edinburgh, as is also the case in many of the most important towns in England and Scotland, is in the hands of the Corporation, and was finally decided on late in 1893, when the work of designing and superintending the whole scheme for public and private supply was entrusted to Prof. Kennedy. Work was commenced at the station and in the streets in May, 1894, and the station was opened for the continuous supply of electrical energy on April 11, 1895, the exceptionally severe winter having seriously delayed the progress of the station buildings.

Districts.

From the electrical point of view the city of Edinburgh may be said to consist of two districts, differing from each other both in character and in their positions relative to the centre of the city. The older part of the city by the castle and the district north of Princes-street include the greater part of the business premises, together with a residential district in which the houses are large and closely built, and where the demand for current may be expected to be great. The district to the south and east of the central portion is either residential or of such a character that the demand for current can never be as large as that in the northern and central district. The residential part of this district contains many houses which stand detached from one another, thus diminishing considerably the possible number of lamps in proportion to the frontage. Having regard to the different districts to be served, and taking into account all the local circumstances, it was decided, after comparison of the various systems of supply and distribution which could be used, to adopt a low-tension three-wire system for the central and northern district, and an alternating-current high-tension system for the southern and eastern district, both systems being worked from one central station and under the same control and management. A good site was found for the central station between the Caledonian Railway and Dewar-place. The foundation here is rock, and the station being on the railway, coal is brought direct into the boiler-house in the railway trucks at a minimum of expense. The position of the site is such that, while being fairly central, it is in a neighbourhood where there is little chance of complaint as to nuisance, real or otherwise.

Station.

The building, which is a handsome brick erection with brown stone frontages to Dewar-place and Torphichen-street, is from the designs of Mr. J. Cooper, the burgh engineer, and was erected under his superintendence. The site is roughly triangular; the boiler-house occupies nearly the whole of the north side, and the two engine-rooms are parallel to and south of it; the general offices occupy the extreme south of the site, and are large enough for the accommodation of the whole of the clerical staff, as well as for the resident engineer and his assistants. Above the boiler-room are the workshops; and the floor above the western end of the engine-rooms is used for the battery-room, storeroom, and meter store and testing-rooms. The eastern part of the engine-room is covered with a light iron roof, with ample provision for light and ventilation. The boiler is covered with a concrete floor, which will ultimately be used as a coal-store. There is ample space in the buildings at present erected for considerable extensions without any extra outlay beyond the foundations for new engines and boilers.

Boiler-house.—The boiler-house is 158ft. long by 48ft. wide, occupying nearly the whole of the north side of the site. It is designed to contain 17 boilers, of which at present only the six at the west end are in place. The main flue runs along the centre under the stoking-floor into the chimney, which is placed in the centre of the length of the house, and is 8ft. square inside and 160ft. high, being lined with firebrick for a height of 60ft. The side flues from each boiler enter the main flue at a slight angle, and each flue is fitted with a butterfly damper; a damper is also placed in the main flue close to the chimney.

The boilers are of the dry-backed marine type, each 10½ft. mean diameter and 12ft. long, with two Purves flues, 3½ft. inside diameter, and 166 tubes of 3in. internal diameter. The boilers are of steel, with wrought-iron tubes, and have been built in accordance with Board of Trade rules for a working pressure of 160lb. per square inch above atmosphere. They are fitted with the usual mountings, and have duplicate feed-check valves.

On the top of the boilers are fitted superheaters, each consisting of two nests of tubes enclosed between the top of the boiler shell and a firebrick casing above, with a space left in the centre for the steam-valves, safety-valve, etc. Each superheater consists of 32 vertical flat coils of wrought-iron tube 1½in. diameter, running from a large cast-iron pipe at the back of the boiler to a similar pipe at the front, all joints being outside and protected from the action of the gases. The steam circulates from a standpipe on the boiler to the back leading pipe, through the superheating tubes to the cast-iron pipe at the front, and thence to the main steam-pipe; proper valves are arranged so that the superheater can be entirely shut off and the steam be taken direct to the main steam-pipe. Each superheater is fitted with a safety-valve and draining-cocks. The superheater coils are readily accessible for cleaning and examination by doors at the front and by movable plates at the top, or, if necessary, they can be lifted bodily away from the boiler. The course of the furnace gases is from the furnace to a brick combustion-chamber at the back of the boiler, through the boiler tubes to a wrought-iron smoke-box at the front, thence up and along the top of the boiler, past the superheater tubes to the back, and there down each side to a centre flue under the bottom of the boiler. A damper is provided, by which the gases can be sent direct to the sides of the boiler without passing the superheater tubes. Sinclair's mechanical stokers are fitted to each boiler, and are worked from two lines of shafting, which are carried by the columns of the boiler-house and driven by an electric motor.

Steam is taken from each boiler through a standpipe, with valves to the superheaters, and from the latter through a large copper bend to the main steam-pipe, which forms a complete ring round the present boilers. This ring joins the engine-room main at two points, and is provided with valves, so that the failure of any one pipe will put only the corresponding boiler out of use. Drain-valves are placed wherever water may accumulate, and are all connected to a steam-trap, which returns the condensed water to the feed-tank.

The pump-room is opposite the chimney, and is entirely closed in. It contains at present one duplex steam-pump and two three-throw pumps driven electrically; each pump has a maximum capacity of 4,500 gallons per hour. The electrically-driven pumps are specially designed to run with a large range of speed, and for this purpose can be connected with either the 230-volt or the 115-volt mains. The steam-pump has its steam supply connected with two points of the main steam-pipe, and its exhaust is connected with the feed-heater. Each feed-pump has an independent suction from the feed-tank, and two independent deliveries into two separate lines of pipes, each of which can be connected with either range of the two duplicate rings of feed-pipes, either through the feed-heater or direct. The duplicate rings of feed-pipes are carried round the stoke-hold in chases in front of the boilers, and each boiler is connected with both rings of pipes by separate feed-check valves delivering into a common internal pipe. A Kennedy water-meter is connected with one range of feed-pipes, so that the whole of the water going to the boilers can be measured. In the pump-room is placed the electric motor for driving the mechanical stokers with its countershaft, and there is ample space for more pumps when they are required.

Under the pump-room is the feed-tank, which communicates with a large storage tank at the end of the boiler-house; another feed-tank is also provided under the workmen's room, so that there is an ample reserve of water in case of accident to the water supply. A siding from the Caledonian Railway runs into the boiler-house, and the coal brought into the railway trucks is at present stored in the east end of the boiler-house. On the station being extended the coal will be stored over the boiler-house and let down through shoots to the mechanical stokers. In designing the plant at present in the boiler-house provision for extensions has been kept in mind, and the arrangements are such that new plant can be added at any time without interfering in any way with the working of that already in use.

Engine-rooms.—The engine-rooms are each about 102ft. long, and are side by side, forming really one room divided by a line of columns which carry the roofs and the beams for the travelling cranes. The engine-room next the boiler-house is reserved for the low-tension plant, and is 46½ft. wide. The other contains the high-tension plant, and is 41½ft. wide. A platform, raised 4ft. above the engine-room floor-level, runs the whole way across the west end of both engine-rooms, and on this are placed the switchboards and regulating gear for both the low and high tension systems, as well as the office of the engineer on watch.

Low-Tension Engine-room.—The machinery at present in the low-tension engine-room consists of eight engines—four of

Digitized by Google

100 i.h.p., two of 250 i.h.p., and two of 360 i.h.p.—with their dynamos; and provision is made for eight more engines of 360 i.h.p. in the future. All are Willans central-valve engines driving their dynamos direct. All the dynamos are two-pole shunt-wound machines with drum armatures, all wound to give 270 volts, except two which are driven by two 100-i.h.p. engines; these two are wound to give 135 volts, being used as balancing machines on the three-wire system.

The steam-piping forms, with part of the boiler-house ring, a complete ring round the low-tension engine-room, and is connected with the boiler-house ring at two points. The main ring is 8in. internal diameter throughout; the straight lengths are of steel, with thick flanges screwed and brazed on; the tee-pieces and valve-boxes are of cast iron, and the bends of copper with steel flanges. All bends are of large radius, and no expansion joints are used or required. The engines are erected in pairs, and are connected with the main ring by two long copper bends; in the main ring a valve is placed between the branches to the two pipes, with a cross-over pipe and valve at the engines, so arranged that the engines can take their steam from either side of the valve in the main ring. The pipes are slung by long rods from brackets fixed on the walls or columns, so as to allow free movement.

In every section of the main ring are placed two drain-valves, one connected with a drain ring, which is common to half the drains, and is connected with a large steam-trap, whereby all condensed water is returned to the feed-tank. The other drain-valve is connected direct to the exhaust-pipe, and is used only on emergency, or when the steam is entirely shut off from that section of the pipes. The separators on all the engines are connected to a second steam-trap, which returns the water collected to the feed-tank; the drains from the cylinders, etc., are connected to the exhaust-pipe. The whole of the steam-pipes and valve-boxes, as well as the drain-pipes up to the steam-traps, are covered with non-conducting composition, and special non-conducting covers are fitted on all the flanges. In fact, every attempt has been made to reduce the loss by condensation in the steam-pipes, which forms so considerable an item in the losses that occur in central-station work.

All the engines are fitted with cooling-pipes in the crank-chambers, to which the water is carried in a line of pipe round the engine foundation block, and taken thence to the feed-tank by a second line. Each engine is fitted with a valve on the exhaust; the exhaust steam is led by a copper bend into the main exhaust-pipe, which is carried in chases in the engine foundation block and along the void between the block and the walls. The main exhaust-pipes are of cast iron, and are led through a Berryman feed-heater in the boiler-house to the chimney. Only one heater is fixed at present, but provision is made for three more when required. From the heater the exhaust steam is carried up to the top of the chimney by a vertical cast-iron pipe 21in. diameter. Valves are provided so that the exhaust steam can be carried direct to the vertical exhaust-pipe without going through the heater.

The whole of the machinery stands on a concrete foundation block 7½ft. thick, which is separate from the foundations of the walls. A void 3ft. wide is left at each side of the block, which is also stopped some distance in front of the switchboard platform, thus forming a large chamber at the west end of the two engine-rooms for the connections, etc. An eight-ton travelling crane, running the whole length of the engine block, is provided in each engine-room for convenience in overhauling, etc. These cranes are worked entirely from below by means of ropes.

Leads.—The main leads from the dynamos are drawn through curved wrought-iron pipes let into the concrete into chases in the centre of the engine foundation block, along which they are carried to the chamber under the switchboard platform. The leads from the field winding of the machines are also carried in the same manner to their regulating resistances, which are placed under the platform; the switches for these resistances are fixed upon the handrail on the platform in front of the switchboard, the leads from the resistances being brought up through the posts of the handrail.

Switchboard and Conductors.—The switchboard and the whole of the apparatus for regulating the dynamos and batteries, and for the distribution of the current, are placed on the platform, and are directly under the eye of the engineer in charge. The switchboard consists of seven slate panels, each about 7ft. high, and stands 4ft. from the west wall of the engine-room, thus allowing ample room to do any work on the connections, etc., at the back. The instruments and gear for regulating the battery are mostly placed on the centre panel, and those for the switching and manipulation of the dynamos and feeders are on the six outer slates; the connections for the positive side of the system are on the left hand, those for the negative on the right, and the middle wire is connected on the centre panel.

The arrangement of the switchboard and conductors is as follows: The feeders enter the building at a cellar under the pavement on the west side, and are brought along the wall under the platform in the form of heavy copper rods, which are carried on insulators, and pass up through the floor to their respective terminals at the back of the switchboard, and are attached to the terminals at the top of the board by cones and nuts. They are connected, through a duplex fuse and an ampere-meter, to heavy vertical copper bars on the front of the slates, each bar having three holes in it, through which plugs can be inserted. The leads from the dynamos are carried in the form of insulated cable to their respective terminals at the back of the board, near the bottom; and through fuses, automatic switches, and ampere-meters, are connected to vertical copper bars fixed to the front of the slates, similar and parallel to the feeder bars. The automatic switches are so constructed that the switch, after being closed by hand, is held in place as long as the current flowing through it exceeds from 15 to 20 amperes; should it fall below this, a trigger is released and the switch is automatically opened, thus breaking the circuit and preventing damage if a machine should fail from any cause. Three heavy copper "omnibus" bars are fixed horizontally at the back of the three outer slates on each side, and are capable of being connected to any of the feeder and dynamo bars of that side by means of heavy copper plugs, which are inserted through holes in the vertical bars and slates, and screw into the omnibus bars at the back, the contact being made on the front bars by a faced collar. The feeders under ordinary circumstances are all connected to the top omnibus bar, and are all in parallel. In order to connect any dynamo to the feeders, plugs are screwed into the top holes of the vertical bars corresponding with that dynamo, the brushes of the machine are put down upon the commutator, and the stop-valve of the engine is fully opened so that the engine is running on its governor; the switchboard attendant regulates the E.M.F. of the machine until it is equal to that shown on the voltmeter between the top bars, and then closes the automatic switch, putting load on the dynamo by taking resistance out of its field circuit. During the whole time the machine is on circuit it is regulated by the switchboard attendant, the engine running on its governor with the stop-valve full open; the engine-driver has to attend only to the running of the engines and dynamos. For the sake of economy, however, the engines are run somewhat slower at low loads than at full load; after about three-quarters of the full load has been reached, the setting of the governor is altered, and the engine run at full speed. In order to take the machine off circuit, resistance is put into the field circuit until the current falls so low that the automatic switch opens; the driver then lifts the brushes out of contact, and shuts down the engine.

Balancing Machines.—The foregoing description applies only to the high-volt machines; the connections for the balancing machines are somewhat different. The leads for each of these dynamos are connected—through fuses, ampere-meters, and automatic switches, as for the high-volt machines—to two contacts of a double-pole switch on the centre panel; and can be connected alternatively with two of three contacts, one of which is connected to the middle wire and the other two to dynamo bars on the positive and negative sides of the switchboard respectively. Thus each balancing machine can be put between the middle wire and either the positive or the negative side of the switchboard. These machines are run in exactly the same manner as the high-volt machines, and the whole of their regulation is done from the switch platform.

In the circuit of each dynamo is a registering ampere-hour meter, from which are taken readings whenever the machine is started and stopped, and the station records of the units generated are made up from these readings. Voltmeters are provided, which can be connected to the terminals of each dynamo by means of multipolar switches; other voltmeters are also connected, so as to show the E.M.F. between any of the omnibus bars on the positive and negative sides, and also between the omnibus bars and the middle wire. A pair of voltmeters are fixed on the upper part of the centre slate, and are connected through multipolar switches, so as to show the pressure between the middle wire and the positive and negative wires respectively at any feeding point on the system, and for this purpose light wires are brought back from the feeding points. The switchboard attendant is thus able to know directly the E.M.F. on the distributing mains, and regulates the E.M.F. at the switchboard so as to keep this constant.

The two lower horizontal omnibus bars can be connected by plugs to any feeder or any dynamo; by this means it is possible to run any feeder or feeders at a higher or lower E.M.F. than the others, should occasion arise. The same two bars are also used for testing and for the introduction of standard instruments into the circuit of any feeder, dynamo, or battery, for the purpose of checking or calibrating the switchboard instruments without breaking any permanent connections or running the circuit on temporary connections. The instrument or standard resistance, etc., is connected between two of the omnibus bars, and the dynamo or feeder, etc., is plugged on one of the lower omnibus bars; the current passes through the resistance, etc., to the top bar, which is on the outside circuit. In the actual running of the station considerable use is made of these spare omnibus bars.

Battery.—In ordinary circumstances the two outer ends of

Digitized by Google

the batteries are plugged on to the top omnibus bar on the positive and negative sides of the switchboard, but can be disconnected either by removing the plugs or by the emergency switches. One of the cells near the inner end of each battery is connected with the middle wire through the regulating switch. Save under exceptional circumstances, however, the E.M.F. of the whole battery in series would be much too high for the circuit, and therefore by means of a regulating switch any number up to 26 of the inner cells of each battery can be put in parallel with the inner cells of the other battery, thus keeping the E.M.F. of the battery the same as that required at the omnibus bars to which the feeders are connected. When the dynamos are running the battery-regulating switch can be set so that no current is passing into or out of the battery; putting more cells in parallel will lower the E.M.F. of the battery, which will then be charged by the dynamos, while putting fewer in parallel will raise the E.M.F. of the battery, and cause it to discharge and thus to help the dynamos. Under normal circumstances the battery is charged while the load is light, more or less current being put into the battery as the load on the external circuit varies, so as to keep the engines running at that time as fully loaded as possible. During heavy load the battery is kept as far as possible with no current going either into or out of it; only after the dynamos are stopped is it discharged at all heavily, or when the load suddenly rises, and then only for short intervals. This method of regulating the battery by putting the centre cells in parallel, which is due to Mr. B. M. Jenkin, necessitates connecting up to the regulating switches more cells than the usual arrangement of regulating by cutting out cells on the outer end of the batteries; but it renders the manipulation of the battery much more simple, and does away to a great extent with the somewhat troublesome charging of the back cells—that is to say, the cells at the outer end of the batteries—which also in the usual arrangement may be used for only a few hours, or even only a few minutes in the day, while they have always to be charged and kept ready for work.

Battery Connections.—The connections to the battery are shown on the diagram, whereon is roughly indicated the actual manner in which the switches, etc., are arranged. The connections may appear somewhat complicated, but in actual work the regulation of the battery is effected by moving only one wheel, like a steering-wheel, fixed on the middle slate of the switchboard. The switches themselves are placed in the battery-room above, and are worked by wire ropes from the wheel below. A special circuit and switch is provided, by which the cells that are in parallel can be charged independently of the rest of the battery; but in actual work this is not regularly used. In this arrangement of battery regulation the whole of the cells in the battery are always used, but the centre cells are not charged or discharged to such an extent as those which constantly remain in series. By properly choosing the time of charging, the regulating cells can receive rather more charge than they discharge; and in order to enable the charging to go on at light load when there is only a small drop on the feeders, the "hospital" or "milking" cells are connected up, as shown in the diagram, four on each side of the system, through two small switchboards on the switch platform. By suitably arranging the switches these cells can either be put in series with the main battery, or be put between the dynamo charging the battery and the feeders; in the latter case, part of the current goes to the battery and part on to the circuit. The E.M.F. of the dynamo charging the battery can thus be made higher than that required at the station end of the feeders, and the battery can be charged with more of the regulating cells in series than would be possible if it was in parallel with the circuit. This arrangement has the additional advantage that full use can be made of the hospital cells, which are usually standing idle unless any cell in the battery requires assisting. When used for this last purpose, the hospital cells are cut entirely off the circuit, and are put, two in series, in parallel with any cell which shows signs of weakness during the discharge of the main battery; connections are made from the hospital cell switchboards in the engine-room to terminals in the battery-room, and adjustable resistances and ampere-meters are put into each of these circuits, so that the current passing from the hospital cells to the weak cell can be regulated, and is always under control of the switchboard attendant.

Battery-room.—The battery-room is directly over the west end of the low-tension engine-room, and is reached by a spiral staircase directly from the switch platform. It has a fireproof floor covered with acid-resisting asphalte, and is well lighted and ventilated, having windows on both sides of the room, as well as a ventilator in the ceiling. The battery consists of 132 cells of the new Crompton-Howell 31-plate type. It is divided up into two half-batteries—positive and negative—and is arranged in two tiers on four rows of stands, which are of cast iron with wooden longitudinal bearers carrying the cells; the eight hospital cells are arranged on separate stands. All the cells are similar, and have each a nominal capacity of 1,000 ampere-hours, the normal rate of discharge being 200 amperes. They are contained in lead boxes, and stand on glass oil insulators upon the longitudinal wooden bearers. The 26 cells in each half nearest the middle wire are connected up by solid copper rods with the regulating switchboard, which stands directly over the main switchboard below. Provision is made for a second battery of similar size, should it be necessary in the future. In the battery circuit there is a registering ampere-hour meter between the outer end of the battery and the switchboard, so connected that its pointer goes backwards on the dial during the charging of the battery and forwards during the discharge. The mechanism is such that the pointer is 10 per cent. slow on the charge; thus if the pointer is always brought back to zero by charging the battery, 10 per cent. more current will be put into the battery than is taken out. This percentage can be altered from time to time as may be judged necessary. The regulating switchboard is connected up to the battery bars on the main switchboard, which are similar to the dynamo bars, and is also connected up to the middle wire. These connections, as well as the special connections for charging the parallel cells and for the hospital cells, are carried in the form of bare copper rods by insulators on the engine-room wall to their respective terminals. The battery has ample capacity to meet the whole of the load of the station from daylight till the evening; thus, during the summer time it can do the lighting during more than half the whole 24 hours.

High-Tension Engine-room.—The high-tension portion of the station consists at present of only two engines and alternators with their switchboard, and the rectifiers for arc lighting with their regulating arrangements and switchboard; but in the immediate future this plant will be considerably extended. Each of the alternators is driven direct by a Willans three-crank engine of 150 i.h.p. on the same bedplate. The alternators are of the "Portsmouth" type, with some modifications necessary owing to their increased speed of 450 revolutions per minute. Their armatures are stationary, and are of great strength; the core, consisting of sheet-iron segments, is solidly bolted into the framing of the machine, with the coils threaded through holes in the sheet iron, well insulated, and completely enclosed in brass boxes. The field magnets revolve, and consist of two heavy cast-steel discs, having on their circumference claws projecting sideways alternately over the field winding, which is between the discs and is well protected from injury. The exciting current is taken from the low-tension switchboard at 230 volts, and is only a few amperes. The alternators work at an E.M.F. of between 2,000 and 2,200 volts with a frequency of 52½ complete alternations per second. The main leads from the alternators, which are concentric, as well as the leads for the exciting current, are taken to the switchboard in chases similar to those in the low-tension engine-room. The arrangement of steam, exhaust, and drain pipes is similar to that already described for the low-tension engine-room.

Switchboard.—The switchboard stands on the switch gallery, and is built up of slabs of slate, forming shelves projecting from the west wall of the engine-room, and divided up into compartments for each alternator and circuit by slate partitions. The outer pole of each circuit and each alternator is connected to an earth-plate at the station, the whole of the rest of the system being insulated from earth. Owing to this arrangement all the switching can be done on the inner pole, which renders the switchboard and its manipulation very simple. The inner pole of each alternator and each circuit is connected to two similar switches through ampere-meters and fuses, and can by these switches be connected to either or both of two omnibus bars at the top of the switchboard. In this way any alternator and any circuit can be connected, and the system can be worked at two different E.M.F.'s if necessary. The primary object of this arrangement, however, is to enable a machine to be thrown into circuit rapidly by running the machine up to full volts on one omnibus bar and changing circuits over from the other omnibus bar on which the other machine is running without having to synchronise the second machine. The two omnibus bars can then be synchronised, the alternator and circuits changed over at leisure, and all the circuits and alternators run in parallel. In the outer circuit of each alternator is connected a registering watt-hour meter for measuring its output. Voltmeters are connected between both of the inner omnibus bars and the outer omnibus bar, and duplicate synchronising transformers with lamps and switches are provided between the two inner omnibus bars. In the exciting circuits are ampere-meters and regulating resistances, the switches of which are placed opposite the switches and ampere-meters of their respective machines. At present the switchboard is arranged for only two alternators and two circuits, but it can be readily extended when required, the gear for new circuits extending in one direction, and that for new alternators in the other. The two circuits are at present connected only to the rectifiers for arc lighting.

Rectifiers.—Opposite to the alternators, and standing on the same foundation block, are placed the Ferranti rectifiers for the series arc lighting. These are three in number—one for each of the two circuits, and one to spare. They each consist of a self-regulating transformer, of which the primary winding is connected to the omnibus bars of the high-tension switchboard, and the secondary winding is connected through a commutator and distributing switchboard to the arc lamps. One winding is hung

Digitized by Google

on knife-edges in a frame, and is capable of movement nearer to and further from the other; this automatically keeps the current in the secondary winding constant at 12 amperes, varying the E.M.F. to suit the number of lamps in circuit. The current from the secondary winding of the transformer is then changed, by a commutator driven by a synchronous motor, from an alternating current to a uni-directional pulsating current, which is distributed to the lamps. A small distributing switchboard is placed close to the rectifiers, by means of which any rectifier can be put on to either of the high-tension omnibus bars, and either circuit of arc lamps can be put on to any rectifier, and provision is made on this switchboard for extending the number of arc lamp circuits.

Schedule of Machinery and Plant in the Station.—In the boiler-house, six boilers of 10ft. 3in. mean diameter and 12ft. length, each estimated to evaporate actually 10,000lb. of water per hour; all fitted with superheaters and mechanical stokers; contractor, Mr. G. Sinclair, Leith. One duplex steam feed-pump. Two electrically-driven feed-pumps.

In the engine-room the low-tension plant comprises eight Siemens dynamos; two have each an output of 450 amperes at 135 volts; two of 220 at 275; two of 600 at 260; and two of 865 amperes at 260 volts. The contractors for the engines, dynamos, steam and exhaust piping, feed-pumps, heaters, etc., were Messrs. Siemens Bros. and Co., who also supplied the switchboard and all connections.

The high-tension plant in the engine-room consists of two alternators, each having an output of 40 amperes at 2,100 volts; a high-tension switchboard; and three rectifiers for arc lighting, with switchboard. The contractors for the whole were Messrs. S. Z. de Ferranti.

In the battery-room, 140 Crompton-Howell 31-plate cells, for which the contractors were the Crompton-Howell Electrical Power Storage Company.

Mains.

In the three-wire system of distribution for the northern and central districts, the E.M.F. between the two outer conductors, positive and negative, is 230 volts, while that between the middle wire and the positive or negative is 115 volts. The latter is the E.M.F. of the lamps on the consumers' premises, no trouble being now experienced in obtaining incandescent lamps to work at this E.M.F., or even higher. Distributing mains are laid throughout the streets marked by red lines in the map; all three wires are laid in those streets where the demand for current is large. In the other streets the positive and middle wires are laid on one side of the street, the negative and middle on the other, and a spare way is left on each side for a third conductor, should the demand require it. The distributing mains are all in parallel, and are connected up throughout the system; rings are completed wherever possible, so as to ensure equality of pressure, and to admit of disconnections being made without interrupting the supply.

Feeders.—The feeders from the station, which are marked by blue lines in the map, are connected to the distributing mains at 16 points. They consist of two conductors only, the positive and negative; the middle wire is inter-connected throughout as much as possible, and is brought back from three districts on the system. The cables are put in parallel at the station, and one connection only is made to the switchboard. The positive and negative sides respectively of all the feeders are put in parallel at the switchboard, but any feeder or feeders can be put on a separate machine if required.

Balancing.—As far as possible, consumers in each street and district are balanced against one another by connecting them alternately between positive and middle wires and between negative and middle wires; large consumers have all three wires taken into their premises, and their lights balanced against one another in a similar manner. But however carefully this balancing is done, it is impossible to get a really accurate balance; the "out of balance" current varies from hour to hour and even from minute to minute, and is different on different days of the week. The amount out of balance is compensated for at the station by means of the balancing machines, one of which can be put on either side of the system; the balancing during the light load is done from the battery alone. Light wires, forming potential leads or pilot wires, are brought back from all three conductors at each feeding point, and are connected to the feeder voltmeters on the switchboard, so that the pressure at the feeding points at any part of the system is directly known at the station, and the necessary regulation made for keeping the E.M.F. constant. The distributing mains are brought back to the station, but are used only for the supply of light and power there; no regulation is done on the mains anywhere, except to the feeding points.

High Tension.—No high-tension feeders or distributing mains have yet been laid. They will be laid as concentric cables in ring circuits, and banked transformers in small sub-stations will be used wherever advisable, while houses in districts where the lighting is scattered will be served by isolated transformers. The concentric cables will be pulled into Doulton stoneware casings under the footways, and into cast-iron pipes under the roadways. The casings have already been laid in those streets which have been opened up for the low-tension mains, and the work of laying the high-tension mains in the southern and eastern districts is now being proceeded with.

(To be continued.)

Discussion.

The **President**, in opening the meeting for discussion, referred to the fact that Mr. E. W. Monkhouse, the Edinburgh electrical engineer, was present, and would be able to answer questions as to the working of the station.

Mr. W. H. Patchell, the engineer to the Charing Cross and Strand Electricity Supply Corporation, doubted the advantage of using alternate-current machinery in the station for the supply of the scattered district, and advocated rather the use of high-tension continuous-current transformers. He approved of the statement that the ordinary feed-pump was a steam eater, but would like to hear if the electric pump was cheaper in practice. He believed that it was easy to prove on paper a balance of advantages for either system. He stated that he had been experimenting on superheating, but had not succeeded in getting the superheat beyond the stop-valve. He had obtained 10 per cent. superheating, but the whole of this was absorbed in the steam pipes.

Mr. W. Geipel regretted that the author had not given the cost of the plant laid down at Edinburgh. He most strongly approved of superheating the steam, but asked if the position of the superheaters had been found satisfactory. When the boilers were being forced the temperature of the gases passing over the superheaters would, he thought, be sufficiently high, but he doubted if that would be the case at light loads, when, owing to the low velocity of the steam in the pipes, the superheat was specially needed. He approved of covering the flanges of the steam-pipes, as he estimated that every square foot of surface exposed required the consumption of half a ton of coal per annum if the steam pressure was on continuously. He also asked if anyone present had observed deleterious effects from the use of steel flanges on copper pipes owing to electrolytic action. As regarded the system of supply, Mr. Geipel could not see the advantage of mixing up the various types of machines and so multiplying the number of units and spare set. He would have preferred to use the alternating-current system only, and to instal larger units. After referring to advantages which would accrue by adopting some standard frequency with alternating currents in England, he concluded by criticising the use of omnibus bars in the low-tension system.

Mr. S. Baynes did not agree with Mr. Geipel as to the troubles that would occur in the future if omnibus bars were used. At Bradford it was assumed that such would be the case, and rheostats had been provided in the feeders to correct for the difference of voltage. He had found, however, that as the load on the station had increased no such difficulties occurred, and that a number of feeders could be selected which could be worked satisfactorily when grouped on omnibus bars. The difficulty of regulation would be still further overcome if higher-voltage lamps were employed, as he hoped to do at St. Pancras.

Mr. W. H. Patchell, in reply to Mr. Geipel's query about the electrolytic action when steel flanges were used on copper pipes, said that he had found no such action when the feed water used was hard. On the other hand, with South London water, which had a somewhat alkaline reaction, he had experienced much trouble, and the corrosion was always at the bottom of the pipe, where the water would naturally assist the electrolytic action. In fact, one set of steam-pipes were condemned for that cause.

Mr. E. W. Monkhouse placed a most interesting diagram before the meeting, which showed the growth of the demand since the station was opened and the details as to cost. The equivalent number of lamps connected had increased in that time from 2,500 up to 34,000. The cost per unit generated worked out each week had naturally fluctuated with the lighting hours. The maximum value was 1·78d., and occurred in the eighth week after opening. The lowest cost per unit was ·886d., and the average now stood at about ·9d. For the past week the detailed cost were as follow: Station charges, ·127d.; wages, ·313d.; fuel, ·319d.; stores, ·026d.; water, ·034d.; repairs, carbons, etc., ·088d., making a total of ·907d. The units sold were 90·8 per cent of the units generated, so that the cost per unit sold was only a penny, which was not bad for a station only six months at work. He had observed that the coal required to keep a boiler banked was, in the summer, 3cwt. The steam-pipes did not vibrate. The low-tension mains now laid consisted of 22 miles of distributing network and 2½ miles of feeders. About 8 miles of high-tension mains were now being constructed.

Mr. H. R. J. Burstall, in reply, said that the question of the system to be used at Edinburgh had not been decided by guesswork, but that the details of six different systems of supply had been carefully worked out and compared. He did not consider that constant-current transformers were suitable for a scattered district, where it did not pay to lay down low-tension distributing mains, and the demand in those parts of Edinburgh supplied on the alternating system would not warrant that step for some years. Hence transformers in the consumers' premises would be used. As regarded the general question of direct current and alternating, he held that each town must be considered by itself, and that it was impossible for any engineer to lay down definite rules on the subject. With respect to the electrolytic action in copper steam-pipes with steel flanges, his six years of experience with such work had not shown any defects in the system.

Prof. Kennedy, after passing a vote of thanks to the author of the paper, referred to some trials which he made with the super-

Digitized by Google

heaters in September. He obtained 10deg. of superheat, and the temperatures in the flues before and after the superheating were 738deg. and 534deg. respectively. Alterations were suggested by the trials, which he expected to considerably increase the efficiency of the apparatus.

AN EXPERIMENT IN WATERWHEEL GOVERNING.

BY WILLIAM W. HANDY.

It is well known among engineers that waterwheels constitute the most difficult class of prime movers to govern, and also that prime movers require very close regulation when running dynamos.

Now just at this time, when water power is being so largely used for electrical transmission, the need of good governing is more felt than ever before. In an experiment carried out by the author on a turbine plant supplying current for incandescent lighting, very good regulation was obtained by means of a simple electric governor.

The diagram, Fig. 1, shows the principle on which the governor works. Connected to the dynamo, 1, is a shunt coil, 2, and a series coil, 3. These coils are connected to the dynamo in such a way that the action of one opposes

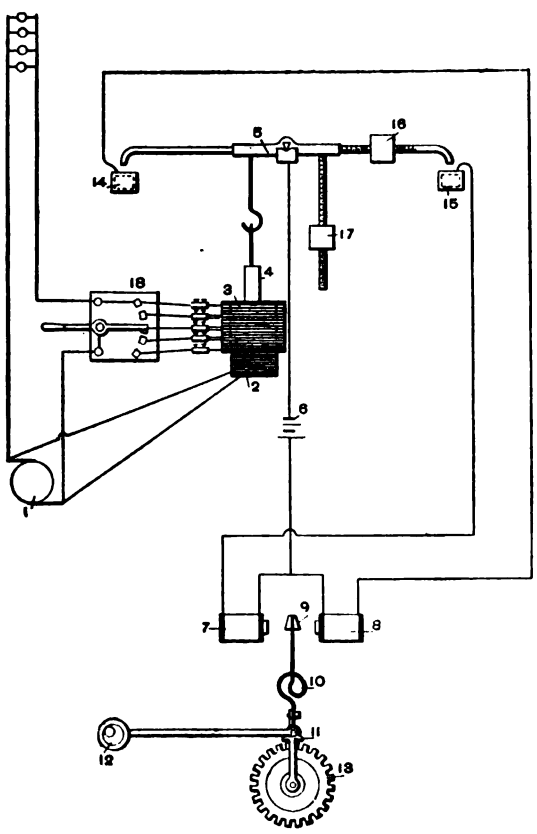

FIG. 1.

that of the other. The coils attract a plunger, 4, which is suspended from a lever, 5; 14 and 15 are mercury-cups into which the ends of the lever may dip. These cups are connected, as shown, to the magnets, 7 and 8; 6 is a storage battery connected, as shown, to the lever and the magnets. It is readily seen if the lever, 5, moves from a central position it closes the circuit through one of the mercury-cups and causes one of the magnets, 7 or 8, to become excited.

These magnets act on an armature, I, which is connected by the spring, 10, to the double pawl, 11. The pawl obtains constant reciprocating motion from the eccentric, 12, which in turn obtains constant motion from the waterwheel. As the armature is attracted by one or other of the magnets the pawl is caused to engage with the ratchet wheel, 13, and turn it in a direction depending on which magnet attracts the armature. The ratchet wheel is connected to the gate shaft of the waterwheel, and as the ratchet wheel turns the gates are opened or closed, thus governing the speed of the waterwheel. When neither of the magnets are excited, and therefore the armature not attracted by either, the pawl is held in a central position by means of a spring, not shown in the diagram, and the ratchet wheel, and, therefore, the gates, remain still.

Now, suppose the dynamo is running at the right voltage with no load on, and consequently with a current through the shunt coil, 2, only, the weights, 16 and 17, being adjusted on the lever, so as to balance the pull of coil 2, just sufficient to keep the lever in a central position. Now, when the full load is thrown on the dynamo, it is desirable in constant-potential distribution to keep the voltage constant at the end of the line, and this is attained by this governor in the following manner: due to the increase of load, and the consequent decrease of speed and voltage, the current through the series coil, 3, will increase, and through the shunt coil, 2, decrease. The pull on the plunger will decrease, and the lever will make contact in cup, 15, magnet, 8, will be excited, the armature, 9, attracted by it, and the pawl will turn at the ratchet wheel, 13, so as to open the gates. This will continue until the speed, and therefore the voltage, has increased sufficient to increase the pull of the shunt coil, 2, and break contact at 15, when the governor will stop working. Now, if the strength of the series coil, 3, has been properly adjusted by means of the switch, 18, contact will not be broken at 15 until the voltage of the dynamo has been increased to the desired amount to overcome the drop on the line, and keep the voltage at the end of it what it was for no load. Now, if the load is decreased it can readily be seen that the lever will make contact at 14, and cause the gates to close, and this will continue until the voltage has decreased sufficient to break contact at 14. The voltage for this load will be found to be the proper value to keep the voltage constant at the end of the line.

The practicability of this governor has been demonstrated, and the curves shown in Fig. 2 give the results of

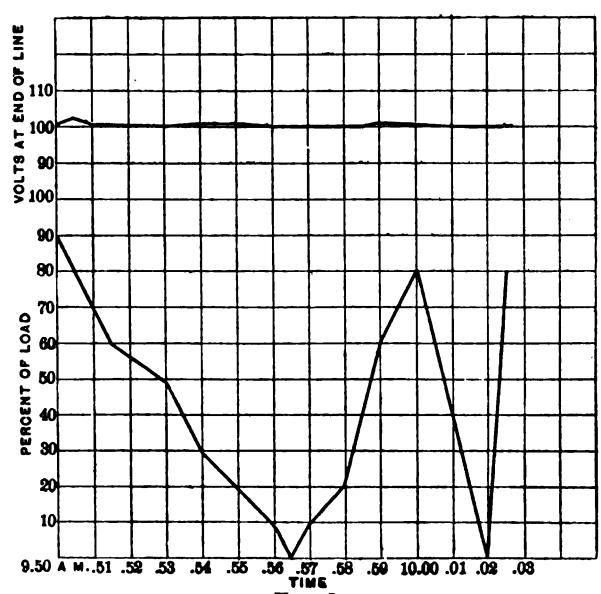

FIG. 2.

a test taken from a small plant on which the governor was working. The dynamo was a continuous-current shunt-wound machine, used for incandescent lighting at 100 volts. The waterwheel was a Burnham turbine, with register gate. The drop on the line was 7 per cent. at full load, and a constant voltage was desired at the end of it. The readings shown by the curves were taken at the end of the line, and show very plainly that under extreme variations of load the voltage was kept practically constant, the difference between the highest and lowest reading on the voltage curve being only two volts.

WHAT, WHEN, AND WHERE.

Institution of Junior Engineers.

November 1, 8 p.m.—At the Westminster Palace Hotel. Presidential address by Archibald Denny, M.I.N.A.

North-East Coast Institution of Engineers and Shipbuilders.

October 25, 7.30 p.m.—First business meeting: Presentation of gold medals for papers read during the eleventh session. Opening remarks by the President. Paper on the "Surface Condensing Plant at the Newcastle and District Company's Electric Works, Forth Banks, Newcastle-on-Tyne," by W. Cross. Discussion.

TO CORRESPONDENTS.

All Rights Reserved. Secretaries and Managers of Companies are invited to furnish notice of Meetings, Issue of New Shares, Installations, Contracts, and any information connected with Electrical Engineering which may be interesting to our readers. Inventors are informed that any account of their inventions submitted to us will receive our best consideration.

All communications intended for the Editor should be addressed C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, E.C. Anonymous communications will not be noticed.*

TO ADVERTISERS.

Advertisements should be addressed to the Publisher, 139-140 Salisbury Court, Fleet Street, E.C., and should reach him not later than noon of Thursday. **Special Terms** *for a series can be arranged on application.*

"SITUATIONS VACANT" and "WANT PLACES" Advertisements will be charged at THREE WORDS for ONE PENNY with a MINIMUM charge of SIXPENCE.

TO SUBSCRIBERS.

"The Electrical Engineer" *can be had by Order, from any Newsagent in Town or Country, and at the various Railway Stations; or it can, if preferred, be supplied direct from the Office, on the following terms:—*

	3 months	6 months	12 months
United Kingdom	3s. 3d.	6s. 6d.	13s. 0d
Other Places	4s. 11d	9s. 9d.	19s. 6d

(Post Free Payable in Advance.)

Cheques, Post Office and Postal Orders for Subscription and Advertisements should be made payable to C. H. W. Biggs, *139-140, Salisbury Court, Fleet Street, London, and be crossed "Union Bank."*

BOUND VOLUMES.

Vol. XV. of new series of "The Electrical Engineer" can be had bound in blue cloth, gilt lettered, price 8s. 6d. Subscribers can have their own copies bound for 2s. 6d., or covers or binding can be obtained, price 2s.

EXTENSION.

Most of our central stations are built with a view to extension, yet in some cases when the need of extension has become urgent, there is an apparent indisposition to countenance the extension. Now, a central station is to all intents and purposes a manufactory. True, it does not turn out sheetings, cloth, or steel—it simply turns out energy. However, it will be found that what is true of all other factories and all other businesses is also true of this business. The larger the factory, and the better it is equipped, and the larger the business it does, the better is the resultant manufacture, the cheaper is the work turned out, and the larger are the profits. A baker selling a hundred loaves per diem cannot obtain the same return even by selling at fifty per cent. per loaf profit as can the baker selling ten thousand loaves a day who sells at five per cent. per loaf profit. The capital expenditure per loaf turned out in the first case is out of all proportion to the capital expenditure per loaf turned out in the second case. It is only certain costs that increase proportionately to the work done; other charges decrease very largely with the increase of work. Hence it seems to us that, instead of holding back assent to extension, every authority should eagerly welcome its necessity. Assume a simple case—that twenty thousand pounds have been expended on a central station, designed with a view to extension, and that the apparatus is loaded to its full capacity: it does not mean that the expenditure of another twenty thousand pounds will only double the producing power; the probability is that it will more than treble it, so that the capital expenditure per unit produced will be considerably reduced. It should be seen at once, if what we have suggested is true, that each unit produced after extension has to pay interest on a smaller initial capital, and thus can, if the producer thinks fit, be sold at a lower price to obtain the same return. But further, the cost of clerical work, in fact, all the constant charges, are reduced per unit by the increased business. Hence, from this point of view again, each unit can be sold cheaper if the producer is satisfied with his previous return. Reduction in price assists extension of business, so that the resultant good is found in this direction also. We are not sure that all the municipalities which have embarked upon this work have well-defined aims, but we think, whether for lighting or heating purposes, the death-knell has commenced to ring for gas, so that the ultimate objective of central-station work should be to provide all the artificial light required by the district, and, perhaps, in addition, some of the power and some of the heat. The capital which has been embarked in gas undertakings, even with the above optimistic views, will not necessarily be lost, nor will it necessarily bring in much less return than it does at present. But it is not our province to attempt to prophesy what will become of gas undertakings, but rather to indicate what must take place with regard to electricity. As regards the latter, the simple fact must always be remembered that,

Digitized by Google

like all other manufactures, the production upon a comparatively small scale must be more costly than the production on a large scale, and so efforts should be made to extend with all speed. The sooner the extension suffices to supply the light to the whole district, the sooner will production be at its cheapest and the return at its maximum. Another phase of this question about which there seems to be much difference of opinion is, whether the attempt should be made so to produce and sell as to show a good large amount annually to be placed to the benefit of the rates, or whether the full value of every extension and improvement should be given to the purchaser and no attempt made to show large profits. We cannot attempt to determine this problem—it is in our view indeterminate. There are those who argue that indirect taxation is better than direct, and point out that with the former a man never knows what he pays, nor does he feels so keenly the incidence of taxation as he does when paying direct. There is much to be said on both sides, but with regard to central stations they must, to be successful, earn enough to keep them thoroughly efficient and to pay the annual instalments of capital. If they have something in addition to this, it goes to benefit the rates. Our argument holds good in either case, that the larger the station the more economical it is on all sides, and the greater the benefit it confers upon purchasers and ratepayers.

MAGNETISATION AND CHANGE IN LENGTH OF IRON WIRES.

Dr. L. J. More, of Johns Hopkins University, communicates to the *Philosophical Magazine* some most interesting experiments on the alteration in length of iron wires when magnetised. He first summarises the results of previous experimenters on the same subject as follows:

Soft iron elongates when magnetised. The elongation attains a maximum, and then diminishes with increasing strength of field until a state is reached when the rod returns to its original length. Further increase of field causes the rod to contract. There is no minimum length, the rod approaching asymptotically a limiting value. For a given strength of field, both hardening and annealing diminish the elongation and increase the contraction shown by the rod before it was subjected to these operations (Bidwell). Tension also diminishes the elongation and increases the contraction of the rod. For a sufficiently great tension no elongation occurs, the rod contracting upon the application of the smallest magnetising forces. For a given length, the effects both of elongation and of contraction are greater for thin than for thick rods (Bidwell). S. J. Lochner comes to the conclusion from his own experiments that the converse is true—that thick bars give greater expansion than thin ones.

Very little reliance can be put in these last experiments, and the dependence of the change of length upon the ratio of the length to the diameter cannot be inferred from them. Bidwell used three rods, 10 centimetres long and 2·65, 3·65, and 6·25 millimetres in diameter, and assumed them to be of iron of similar composition. It is well known that different specimens of iron, apparently similar in structure, give results that vary 25 per cent. and more. So that the small variations in the change of length noted by him cannot safely be said to be due to the differences in their diameters, especially as he made no determination of the permeability. Lochner avoided this error by testing an iron rod, and then, after having cut off a portion, testing it again. He, however, took no precautions to have the field uniform. His solenoid was nearly four times as long as the shortest rod used, and the ratio of the diameter to the length of the rod was only 1 to 32. Besides the uncertainties introduced by such a poor arrangement for a uniform field, great errors would be produced by the strong poles created at the ends of the rod.

The author then proceeds to describe his apparatus, which was so constructed that the modulus of elasticity could be conveniently obtained on it. The wire to be tested was suspended from a tall tripod standing on a stone slab. A hole was cut in the slab so that the wire could be passed through it and the free end permitted to almost reach the floor of the room. A hollow brass cylinder, 1·6cm. in diameter and about 68cm. long, was screwed to the wire at a point just above the stone slab. A loosely-fitting cork plug in the upper open end of this cylinder serves to keep the wire in the axis. The wire to be experimented on thus was contained in the tube, and the elongation was measured by a system of levers and mirrors attached to the tube and wire respectively. The most important dimensions were:

Length of wire stretched	69·9cm.
Ratio of lever arms	119/4·65
Distance between needle-points	2·3mm.
Distance to telescope and scale	1,660·0mm.

The multiplying power of the apparatus was therefore:

$$\frac{119}{4\cdot65}\times\frac{1,660}{2\cdot3}\times 2 = 36941.$$

And as the scale was graduated to millimetres, one scale division represented an actual change of length of $2\cdot7\times10^{-5}$ millimetres.

The coil to magnetise the wire stood on the stone slab, and was long enough to reach just below the lever arm, so that the part of the wire experimented on was in a practically uniform field. The principal dimensions of this coil were as follows:

Length of coil	83·7cm.
External diameter	6·3cm.
Internal diameter	3·6cm.
Number of wire	18.
Number of turns	3,045.
Number of layers	7.
Number of turns per centimetre	36·4.
Resistance of coil	10 53 ohms.
Strength of field per ampere	45·74 C.G.S.
Maximum field	260·00 C.G.S.

The core of this coil was made of two co-axial brass cylinders, fastened together by the end plates of the coil. The space between these two cylinders was filled with water, which proved to be an excellent way of retarding the heat effects produced by the current.

With the apparatus the author proceeded to experiment with wire 1mm. diameter under three conditions—*i.e.*, normal condition, hardened wire, and wire under stress. He corrects the results obtained from the contraction due to the $B^2/8\pi$ force. This contraction is obtained from the formula $\frac{\delta l}{l}\times10^7=\frac{B^2/8\pi}{M}$, where M is the modulus of elasticity of the sample.

The following is a summary of the results obtained by this investigation:

1. A relation has been obtained between the elongation due to magnetisation and the intensity of magnetisation of soft iron. When the elongation has been corrected for the contraction caused by the $B^2/8\pi$ force, the relation may be expressed thus: A rod of iron elongates slowly until an intensity of about 800 is reached. After that point the rod elongates more rapidly and attains a maximum value of about 60×10^{-7} part of its length at an intensity of 1,200. With greater intensities the elongation diminishes, the curve being approximately a nearly vertical straight line

2. Hardening the wire diminishes the corrected elongation, and the wire attains its maximum length in a less intense field.

3. It has been shown that when the wire is stretched the change in elasticity due to the magnetisation produces an

Digitized by Google

important effect. Neglecting this correction, the effects of stretching are similar to those caused by hardening the wire.

A SINGLE-PHASE POWER TRANSMISSION PLANT.

It is not well known that the General Electric Company of America has exploited a synchronous system of electric power transmission, but the interesting plant installed by that concern for the Walla Walla (Wash.) Gas and Electric Company, in the spring of 1893, demonstrates this fact.

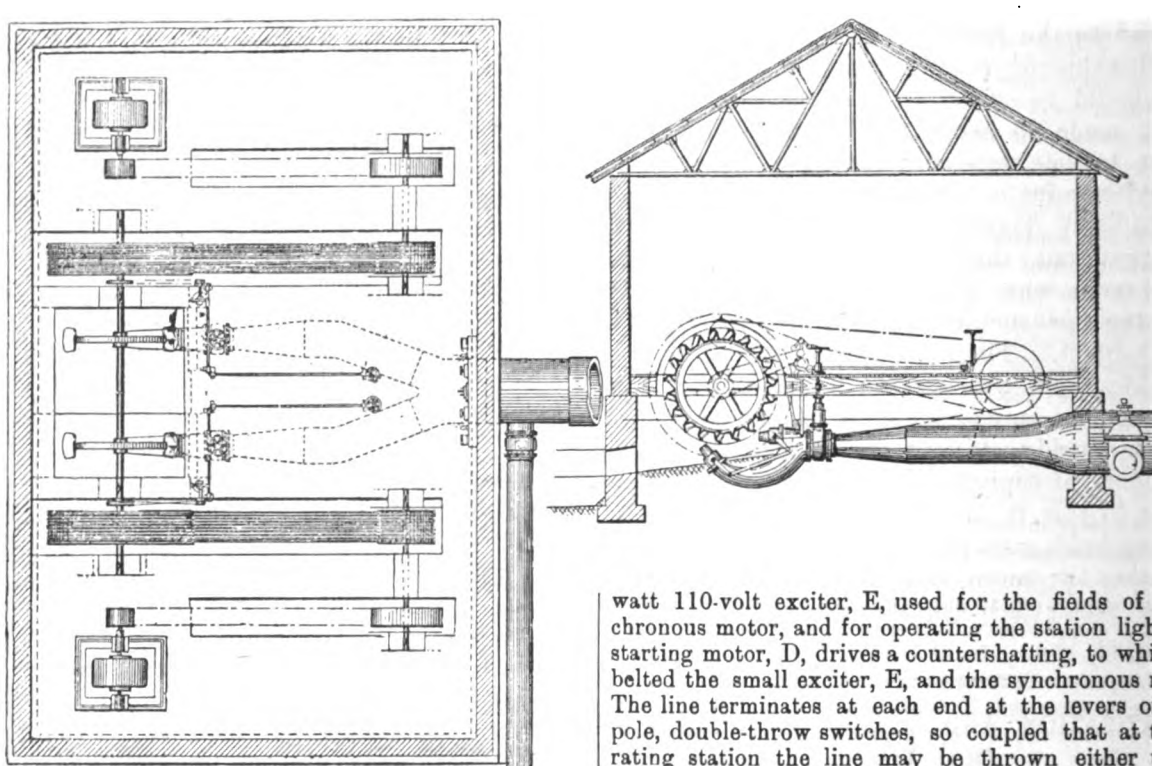

FIG. 1.—Plan of Generating Station, Walla Walla Transmission.

The features of the installation are so distinctive and the plant being placed at a time when the company named was believed to be strenuously endeavouring to devise a system of power transmission that would, at least, be abreast of other manufacturers, led to the conclusion that the plant in question formed a stepping stone in the development of the art. At that time single-phase transmission was in successful operation at Telluride, Col., using the synchronous system of the Westinghouse Electric and Manufacturing Company, and a similar plant was about to be installed by the Standard Consolidated Mining Company, of Bodie, Cal., but polyphase transmission was practically unknown in commercial circles. The Walla Walla Gas and Electric Company felt it to be imperative that the water power of Mill Creek should be utilised to operate its electric light and power plant, and the installation described was placed. That it operates satisfactorily is unquestionable, but it is improbable that similar conditions would now be satisfied by the installation of a plant of its character.

The generating station, which is situated on Mill Creek, a distance of four miles from the city receiving station, is operated by water power, the water being brought in a wood stave pipe, 48in. in diameter, and having a total length of 6,000ft. The effective head is 66ft., and the wood pipe terminates in a sheet-iron Y pipe, supplying two Pelton wheels that are 6½ft. in diameter, supplied with double nozzles and run at 100 revolutions per minute. The capacity of the wheels are 175 h.p. each, which is transmitted to the main countershaft by means of two endless compound rope drives, all as shown in the accompanying outline cut of the plant, Fig. 1. The dynamos are belt-driven from the countershaft, and the plant was laid out for double its present capacity. The synchronous motor at the city station operates power and lighting generators.

The generating station contains one 100-kilowatt single phase 2,000-volt Thomson-Houston generator, having a frequency of 8,000 and being composite wound, together with one 15-kilowatt 500-volt exciter, which from the manner of its use also becomes a starting generator. These machines are shown in Fig. 2 as A and B respectively. The line consists of a single circuit of No. 0 B. & S. wire, leading direct from the generating station to the city plant of the company, a distance of about four miles. This receiving plant contains one 100-kilowatt 2,000-volt synchronous motor, designated as C, one 7½-h.p. direct-current bipolar starting motor, shown as D, and a small 1½-kilowatt 110-volt exciter, E, used for the fields of the synchronous motor, and for operating the station lights. The starting motor, D, drives a countershafting, to which is also belted the small exciter, E, and the synchronous motor, C. The line terminates at each end at the levers of double-pole, double-throw switches, so coupled that at the generating station the line may be thrown either upon the 500-volt exciter or the 2,000-volt alternator, so that at the receiving station the line may be thrown upon the bipolar starting motor, or upon the 2,000-volt synchronous motor. The switchboards at the two stations contain all the forms of instruments usual for the purposes of the currents handled, the entire equipment being complete in every detail.

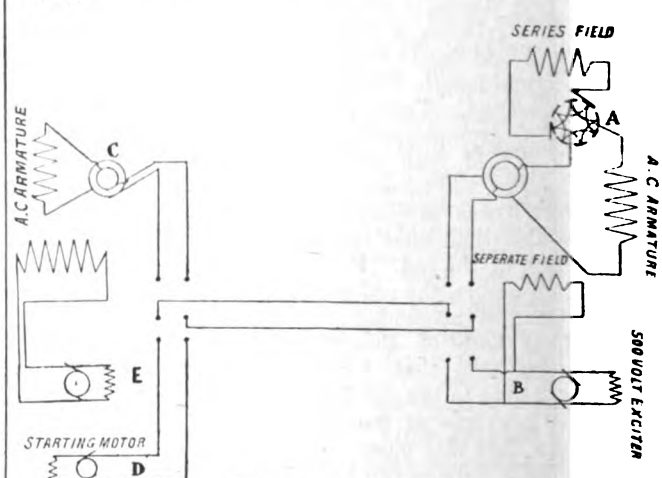

FIG. 2.—Circuit Diagram of the Walla Walla Transmission.

The method of putting the plant in operation is as follows: The generating plant is brought up to speed and the rheostat in the fields of the 500-volt exciter is cut out for maximum voltage. The fields of the generator are excited therefrom, no attention whatever being paid to the voltage of the alternator. The double-pole, double-throw switch is then brought down upon the jaws forming the terminals of the 500-volt exciter, which throws its potential upon the line. The attendant at the generating station has in the meantime telephoned to the attendant at the receiving station that he has started

Digitized by Google

up, whereupon the latter throws the line current upon the small starting motor by bringing down the switch upon its terminals, as shown in the diagram. The starting motor then brings the synchronous motor and its exciter up to speed through countershafting. The armature of the alternator runs idle in dead fields, but the exciter is brought up to voltage and connected with its pilot lamp to avoid error. When the synchronous motor has been brought up to proper speed, the station attendant telephones to the power plant to stand by the main switch, whereupon the motor attendant opens up the main switch and quickly throws in the station transformer operating the pilot lamp and voltmeter on to the line through a primary switch, and then waits for the appearance of the 2,000-volt alternating current before closing the main switch that throws the line to the synchronous motor.

In the meantime the attendant at the generating station, who, in compliance with instructions from the motor-station attendant, has been standing by the main switch, quickly throws the main switch from the 500-volt contact to the 2,000-volt contact as soon as he sees the needle of the current indicator drop back to zero, which obviously is positive information to him that the attendant at the receiving station has cut the starting motor off the line. Thereupon the attendant at the motor station, who has been watching the pilot lamp operated from the station transformer, throws the line upon the synchronous motor with one hand as soon as the lamp comes up to candle-power, and immediately closes the field circuit of the alternator with the other hand. The motor at once comes in step, the starting motor is then shut down by throwing the clutch on its countershaft pulley, and the plant does its work with perfect satisfaction.

The method of starting was designed by Mr. W. A. Burkholder, then district engineer for the Pacific North-West district of the General Electric Company, and who is now general superintendent of the Portland (Ore.) General Electric Company. Provided the speed of the synchronous motor is higher than that of the generator, the motor will invariably synchronise with the generator, and has never given any trouble whatever.

THE JANDUS ARC LAMP.

Yesterday (Thursday) we paid a visit, at the invitation of Messrs. Drake and Gorham, to Messrs. Johnson and Phillips's works at Old Charlton, in order to inspect the arc lamp invented by Mr. Jandus (of the Manhattan Company, New York), who, we understand, has been awarded the Franklin medal for his device. It is stated that the success of this lamp in America has "exceeded all expectations," inasmuch as it is claimed that the lamp burns for 200 hours with a single pair of carbons. The additional life is obtained by enclosing the carbon rods in a small globe of special construction, which is again enclosed in a large globe, hermetically sealed at the top.

On starting the light the available oxygen is at once consumed, and the inner globe is filled with an inert gas which does not promote combustion. The expansion of the gases due to heat expels through a special valve most of the oxygen from the outer globe, which in its turn soon becomes charged with a rarefied gas. This system is not new, but Mr. Jandus has apparently overcome the defect of previous efforts in this direction—the blackening of the globe. The conditions of the arc are found to be such that the carbons can be separated to a greater extent than has hitherto been found possible without flaring. The voltage across the arc is from 75 to 80, with a five-ampere current. The light in the lamps we saw running was steady enough, but doubt was expressed by one or two of the company present as to the candle-power of the lamp compared with the ordinary arc lamp, and we understand that tests as to the candle-power per watt of the lamp are to be independently made by a high authority. The mechanism, which is partly on the dashpot principle, with a magnet suspended inside the coil, is fairly simple. The Jandus Arc Lamp Company, of Manchester, have appointed Messrs. Drake and Gorham, of 66, Victoria-street, Westminster, to be their sole agents for the lamp. Mr. Barton, the managing director of the company, stated at Charlton that the Edison Company in the United States allow consumers using the Jandus arc lamp a rebate of 10 per cent. on account of the saving in trimming.

PLYMOUTH.

REPORT TO THE ELECTRIC LIGHTING COMMITTEE OF THE CORPORATION BY DR. J. A. FLEMING, F.R.S.

(Concluded from page 457.)

CAPITAL OUTLAY.

Until I am in possession of more information than is at present before me as to the location of any arc lighting which may be undertaken, the figures for capital outlay cannot be given in full detail. As before observed, the capacity of any electric station for the supply is properly measured in units called a kilowatt, and this is approximately equal to 1½ h.p. Experience shows that a larger number of lamps than those equivalent to the full capacity of the dynamos can always be connected to the circuits because all the lamps are not in use simultaneously. The ratio of the maximum number of lamps in use to the total number connected will vary according to the nature of the users. In some of the larger town stations not more than 50 per cent. of the lamps connected are ever simultaneously in use. Experience, however, shows that if the lighting consists largely of shop-lighting the difference between maximum number of lamps in use and total number connected is not nearly so great, and will probably be about 75 or 80 per cent. From data obtained from other places I am led to the conclusion that if provision is made in Plymouth for the simultaneous use of 7,500 8-c.p. lamps, about 10,000 such lamps could be connected to the supply circuits.

In addition to this, we have, however, to make allowance for reserve plant in case of accidents, and for a station of the above capacity, and having dynamos units of the size suggested, there should be reserve plant of about 30 per cent.—that is to say, if we provide generating plant of 400 kilowatts capacity, allowing 300 kilowatts for the full working power and 100 kilowatts for the reserve, we shall be able to supply current simultaneously for 7 500 8-c.p. lamps, and to connect about 10,000 such lamps, or perhaps more, to the system. My recommendation therefore is that the station should contain at first five engine-alternator plants, two units being of 50-kilowatt capacity and three of 100-kilowatt capacity. This will provide for an effective output of 300 kilowatts, with 100 kilowatts reserve, the alternators all being capable of being worked in parallel together.

The capital outlay required to establish any station is best estimated in cost per kilowatt. The appended table of statistics has been extracted from valuable information collected by the electrical paper *Lightning*, from Board of Trade returns, and show the capital outlay which has been made upon certain continuous and alternating-current stations already at work. It will be seen that these numbers vary over rather wide limits. In the case of those stations established by companies, there are probably reasons for this which do not appear upon the surface, but if we take the corporation stations established on the low-tension system and those established on the high tension system, it will be seen that the average cost of the seven low-tension stations tabulated is £94 per kilowatt, and the average cost of the six high-tension stations in the appended tables is £93. The average, excepting Burton, which for some reasons is abnormally high, is £84.

A deduction from a larger number of instances would confirm the view which is certainly the correct one—namely, that the average cost per kilowatt of establishing a high-tension station is somewhat less than the average cost of establishing a low-tension station of equal powers.

If we take Portsmouth as a typical instance of a well-designed high tension station, the capital outlay there has been £71 per kilowatt It will also be seen from these tables that the revenue per lamp varies very much in different places, in some being abnormally low, and in others approximating to that which may be considered a fairly average price—viz., 8s. to 10s. per 8-c.p. lamp installed per annum. If at the outset the electric supply from the station is given only from dusk to dawn, and not continuously during the 24 hours, then the ratio of working costs to revenue can be kept down to a figure which will not be far from 50 to 60 per cent. Hence, considering the establishment of an alternating-current station having a total capacity of 400 kilowatts, the total capital outlay at £80 per kilowatt will be about £32,000. To this £32,000 I add another £3,000 to cover contingencies, the uncertain factor as to the amount of constructive work to be done in preparing the ground and waterside for the station, and the architect's and engineer's commissions, making in all £35.000. Hence, it may be considered, that for a well-designed alternating-current supply station, having a total capacity, say, of 400 kilowatts, and a lamp connection of 10,000 8-candle lamps, and spare plant and effective working capacity of 300 kilowatts, the probable revenue would be about £5,000 a year, and the capital outlay about £35,000. On an annual output of 200,000 units it can be shown that the whole operating cost can be brought within £3,500, and thus leave £1,500 to pay the share of sinking fund and interest. As far, therefore, as incandescent lighting is

* These figures include public and private lighting. † Business done by contract not by meter data therefore is unreliable. ‡ For 10 months, March 1 to December 31, 1894 § For 8½ months, April 18 to December 31, 1894 ‖ For 6½ months to December 31, 1894, supply not constant.

concerned, the general scheme for electric lighting of Plymouth should, in my opinion, comprise a station having an ultimate capacity of 30,000 8-c p. lamps, but the initial scheme should only contemplate the actual erection of about one-third of this station.

There is good ground for stating that if started on these lines, and assuming that about 5,000 lamps can be connected soon after the commencement of supply, the result would be that at the end of the first year of working all the operating expenses would be paid, and that by the end of the second year a contribution would be made towards the reduction of the debt and the interest on the same, and that from and after the time when the lamp connection reached 10,000 8-c.p. lamps, it might be fully expected that a profit would be made over and above the amount required for working costs and interest.

The above estimate does not include the arc lighting plant. The general recommendation I make for this portion of the work is that arc lighting plant should be established at first for about 90 arc lamps with proper reserve plant. This will require four direct-driven arc lighting machines—three for use and one spare plant—these being either dynamos or equivalent plant in rectifiers. Separate engines will have to be provided for these arc light dynamos if adopted, but the steam can be taken from the same boilers which supply the steam for the incandescent lighting dynamos. If the rectifiers are employed no separate engines are required, and subject to the consideration of tenders, the expe rience at Portsmouth and other places warrant me in believing that there are strong reasons in favour of employing the rectifiers for the arc lighting plant.

My conclusions therefore on the subject of electric lighting in Plymouth are as follow: (1) That there is every reason to believe that if a municipal electric lighting station is established in Plymouth for the supply of current for public and private lighting, the growth of a demand for the light would be as progressive as in other towns of similar size and character. (2) My opinion is that this station should be on the alternating-current system with transformer sub-stations, and that public street arc lighting should form part of the scheme, the arc lights being operated by continuous currents either generated by separate machines or by the conversion of the alternating current. (3) The station should be planned for an ultimate demand of about 30,000 8-c p. incandescent lamps and 200 arc lamps, but the initial outlay should only comprise plant for 7,500 lamps, and that part of the building necessary for the plant for 10,000 lamps. The chimney stack should be put in for its full capacity at once. (4) The immediate provision for the arc lighting should include plant for about 90 or 100 300-watt street arc lamps, which would be equivalent to lighting about three miles of streets. These lamps to be placed in the principal streets and on the Hoe. (5) The capital outlay for that part of the scheme concerned with the private or incandescent lighting would involve a probable outlay of £35,000. The uncertain factor at the present moment in this estimate is the amount of constructive work which would be necessary to be done in order to plant the station on the Cattewater site in such a position as to be able to utilise water for condensation purposes at all states of the tide. Subject to the opinion of your borough surveyor, I think that this would involve the construction of a quay or wharf, on which part of the station would have to be placed. This part of the outlay would be controlled by the special consideration as to the nature of the foundations to be obtained, the amount of pile driving necessary, if any, and hydraulic work generally. The advantages to be obtained by continuous condensation, especially at the times of light load, are, however, very great, and I should strongly desire to see the station placed in a position to utilise the tidal water for surface condensation at all states of the tide, without having to pump it to a considerable distance. If station buildings were constructed for the first suggested section of the plant having a length of 120ft., width 60ft., and mean height 30ft., a plain but substantial building, constructed with stone found on the site, and taking the average cost at about 6d. a foot, ought to be erected for £5,000. The chimney stack and foundations for the same should be covered by an additional £1,000. The cost of such a building ought therefore not to exceed £6,000 to £7,000. The items estimated approximately would be as follow:

Foundations, buildings, and shaft	£7,000
Engines, boilers, steam-piping, pumps, condensers, dynamos, and switchboards	15,000
Overhead traveller and fittings generally of the station	1,500
Mains and transformers	7,500
Meters and other accessories	1,500
Erection, incidentals, labour, and professional charges	2,100
The total amounting to	£35,000

For this would be obtained an electric station having an effective output of 300 kilowatts, and an installed plant equal to 400 kilowatts in power and capable of maintaining 10 000 8-c.p. lamps in action, placed in and above the centre of the town, with a sufficient reserve plant for all emergencies.

(6.) The provisions for the arc lighting plant, in addition to this, would have to include the arc lamps, cast-iron street arc lamp standards, underground conductors, and arc light machines and engines. The steam would be taken from the steam boilers that supply the incandescent plant. My estimate for the above arc

Digitized by Google

lighting plant is approximately £6,600 for a plant capacity of 90 arc lamps of 300-watt power. These arc lamps would cost to maintain from £15 to £17 per annum, and would entirely replace the gas lamps over a street run of at least 12,000ft. and probably over about three miles, whilst the average illumination of the street surface would be increased in some places tenfold. It is difficult to provide a closer estimate of the capital outlay for the arc lighting until the location of the arc lamps is known and the precise length of the underground conductors necessary.

(7) The income to be derived from such a capital outlay may reasonably be expected to be as follows: If the consumption of current for the incandescent lights proves to be similar to that in other towns of like character, it will be seen by reference to the tables in the foregoing part of the report that with the exception of a few towns in which the revenue per lamp is abnormally low, a fair estimate of the earning power of the 8-c.p. lamp is from 9s. to 10s. per annum, and that, therefore, the income from the 10,000 incandescent lamps would, in all probability, amount to £5,000 per annum. The whole of the generating expenses, not including interest on capital, ought to be covered by £3,500 when the station reaches it full output of 10,000 lamps, hence leaving £1 500 as a contribution towards the interest on loan and sinking fund.

(8) As far as regards the arc lighting the case is even more favourable, because the 300-watt arc is generally rented at from £20 to £25 per annum, and the difference between this and the above-mentioned working cost is quite sufficient to make an ample provision for paying the interest and sinking fund connected with that part of the capital outlay made for the arc lighting plant alone. I consider that on this portion of the outlay there should be no difficulty in earning 8 to 10 per cent. on the capital outlay after the payment of all working expenses connected with the arc lighting. The arc lighting can, in fact, be made self-supporting.

I should prefer to add to the above estimate for the arc lighting 10 per cent. for the uncertain element in the position of the lights and place the total capital outlay specially for arc lighting plant at £7,260.

(9) Space should be provided in the station for an extension of the arc lighting plant up to 180 or 200 arcs, so as to provide for a practically entire arc light illumination of all the principal streets of the town.

(10) The cost of extension of the power output of the station will not be in the same proportion to the original cost, because the initial outlay will bear certain charges for the whole scheme; but my estimate is that a capital outlay of £35,000 will cover the whole cost of the establishment of the incandescent lighting equivalent to a lamp connection of 10,000 8-c.p. lamps in and about the compulsory area, and that about £7,260 the cost of the arc lighting for 90 300-watt arc lamps in the same district and on the Hoe. The gross revenue to be obtained from this lighting, public and private, should approximate to £7,000 per annum, and the net revenue, after payment of all charges, should leave a margin of £1 500 on the incandescent and £450 on the arc lighting to provide the interest on the loan. When the full capacity of the station—viz., 30,000 8 c.p. incandescent lamps and 200 arc lamps—is taken up, there is good reason to believe that a surplus would remain after meeting the interest on the loan.

On the Employment of Refuse Destructors for Power Purposes.

One question on which I was requested to advise in connection with any proposed scheme for electric lighting at Plymouth is the employment of a refuse destructor for generating steam. In the last eight or nine years widespread interest has been aroused on the subject of refuse destruction in towns, and in connection with the subject attention has been given to the possible utilisation of the power represented by the heat given out by the combustion of this refuse. Very different opinions have been expressed by various authorities on this subject, and I may say at the outset that the greatest caution is necessary in accepting many of the statements which have been made on this subject, and also in applying the experience which has been gained in one place to another.

As your borough surveyor is I understand, engaged in collecting information for a report to you on the whole subject of refuse destruction. I have handed over to him a quantity of information which I had collected together on the subject of refuse destruction and the utilisation of the heat for steam generating purposes. I may say, however, that the broad general result I have derived from the consideration given to this subject is that it would be unwise for the Corporation to embark hastily on any scheme which has for its basis a proposal to establish a refuse destructor solely with the view of generating power for electric lighting. The waste heat from a destructor already existing, or which has to be erected purely on sanitary grounds, may be usefully utilised as an adjunct in generating steam for electric lighting purposes, but the statement which has been made that the ashbin refuse of towns is capable of being made available and sufficient for the whole electric lighting likely to be required, is one which has not at present received sufficient confirmation in fact or experience. The general result derived from the actual experience of refuse destructors is that each cell of a destructor is capable of yielding directly by its waste heat on an average 5 h.p., and that such a cell may consume from five to six tons of ashbin refuse per day without the use of forced draught.

Opinions differ very widely as to the economy and utility of using the forced draught, but if we set on one side exceptional cases, and take the above as an average figure, then it is perfectly certain that an amount of refuse destruction equal to about 30,000 tons per annum cannot possibly yield directly the amount of horse-power required in the electric lighting station at the hour of maximum full load. In order to maintain the 10,000 8 c.p. lamps above suggested, something like 500 h.p. or 600 h p. must be available at the time of maximum load, but the direct heat from the refuse destructor of the capacity required for the consumption of the above amount of refuse would not probably amount to more than 50 h.p. to 60 h.p. The matter would have an altogether different aspect if the power generated by the boilers of the refuse destructor could be stored. A scheme has been put before the Shoreditch Vestry, in London, for utilising the waste heat of dust destructors in combination with a system of steam storage invented by Mr. Druitt Halpin. This system practically consists of large tanks or boilers into which the steam from the destructor boilers is passed, and in which water and steam are accumulated under considerable pressure for utilisation at a subsequent time. This experiment of thermal storage and destruction will be watched with great interest by engineers, but it would, I think, be wise to hold back from following on the same lines until some experience has been gained of the safety and economy of such a system of thermal storage in practice.

The one fact that stands out prominently is that the waste heat of the refuse destructor, furnishing at the rate of 1 h.p per ton of refuse burnt, if utilised directly, is not sufficient to supply the power required for the suggested electric lighting in Plymouth during the hours of maximum demand. It might, however, be utilised during the daytime or hours of night, if the destructor station were placed in contiguity with the electric lighting station.

I therefore suggest in this connection that the plans of your borough engineer with regard to refuse destruction in Plymouth, should hold in view the possible utilisation of the waste heat for part of the power required in the electric lighting station, and that the destructor station and electric lighting station may therefore very conveniently be placed in contiguity on the Cattewater site; but at the same time I hold the opinion that the electric lighting station should be made at first entirely independent, and that the question in the forefront as regards a destructor station should be the sanitary one. There will be no difficulty in making the necessary arrangements to utilise the waste heat from the destructor for steam generating and using it as far as possible in the electric lighting station if the two are placed side by side. If subsequently a system of thermal storage enables us to do more than we can at present do by the combustion of the ashbin refuse, that also can be added, but at the present moment I advise strongly that the electric lighting station be made independent of the other.

At the present time we are able to refer to a number of schemes which have been proposed for the utilisation of the waste heat of destructor cells but an examination of what has actually as yet been achieved does not warrant me in advising the adoption of any of the proposals which have been put forward for depending entirely on refuse combustion for the generation of current for electric lighting. As your borough engineer is dealing with the subject, there is no need to enter into further details as to the manner in which such waste heat as is available can be employed in raising steam.

On the Employment of Electric Traction in Connection with Tramcars at Plymouth.

The third question which I was requested to consider in connection with the public electric supply at Plymouth, was that of operating the tramcars by electricity. There are three systems by which electric traction is now being carried out; these are called respectively the overhead system, the conduit system, and the accumulator system. In the first of these systems an overhead wire is run alongside the tramline track. The tramcars are provided underneath with electric motors; generally speaking, two 15-h.p. motors are used. From the top of the car proceeds a trolley pole, which makes contact with the overhead wire as the car moves along. The car picks up its current from the overhead wire, which, after passing through the motors, is returned by the rails. It is this overhead system which has attained such enormous development in the United States. Of the 12,000 miles of tramway in the United States and Canada, it is said that about as much as 7,200 miles are operated by electricity. Some writers state as many as 9,000 miles. There are 20,000 electric cars, and nearly three-fourths of the tramway movement of the United States is electrical. The capital outlay represented by this development is £45,000,000 sterling.

In the conduit system, the electrical conductor which supplies the current is laid underground in a channel or conduit. A projecting steel bar from the car passes down into the conduit through a slit in the roadway, and makes the necessary contact with the electric conductor; otherwise the arrangement of the car is the same as in the overhead system.

The various difficulties in connection with these two systems are now well understood, and for the most part are overcome. In addition to these two systems, there is a third or accumulator system, in which secondary batteries are carried on the car and supply current for the motor. This system would be an ideal system for the operation of tramcars electrically but for the fact of the greatly increased weight of the car, which, when carrying the accumulators and motors, amounts to from 10 to 15 tons, and that it involves all the special difficulties in connection with the working of secondary batteries, particularly those caused by the incessant jolting of the batteries and the very heavy demand made for current at the moment of starting the car, both of which operate to cause a rapid deterioration of the battery.

Deferring for a moment some further criticisms on the accumulator system, the general description of an electric tramcar system

Digitized by Google

operated by overhead conductors is as follows: At some place conveniently situated with respect to the line an electric power station is put down. This power station contains dynamo machines, which generate the current generally at a pressure of 500 volts for tramcar work, and these are for the most part driven by engines of from 300 h.p. to 500 h.p. The tramcars weigh from 8,000lb. to 10,000lb., and carry two 15-h.p. motors. The object of providing this excess of car power is to supply the necessary starting power, especially on gradients. The power is conveyed to the overhead conductor of the trolley wire by underground conductors, called feeders, and when the current has done its work in the motors it is brought back by return feeders from the rails. In order to prevent the current from leaving the rails, and thus causing erosion of gas and water pipes, it is necessary that the rails should be bonded together. In the regulations issued by the Board of Trade for controlling electric traction certain rules have been laid down with respect to the manner in which the rail track shall be constructed, and some of the early difficulties in connection with electric traction arose from the fact that these details had not received sufficient attention. Practically speaking, in order to convert a tramline worked by horses into an electric car line, the track has to be reconstructed to bring it into accordance with these rules, and to render it capable of withstanding the greater wear and tear due to the heavier cars.

There is no difficulty in dealing with very considerable gradients either on the overhead or the conduit system and cars can be made to start uphill on gradients as much as 1 in 10 It is merely a question of sufficient motor power. Objections have been taken to the unsightly appearance of some overhead lines, but there is no difficulty in constructing a neat, well-designed overhead system which is not in the least degree objectionable. Speaking generally, the conversion of a horse-car track into an electric track means relaying of the track and supplying new cars As regards the cost of construction, the following figures have been given as an average specimen of the cost of overhead construction in the United States: the entire track construction, including rails and wires, costs about £1,400 per mile of single track; and the cars, with motors complete, about £800 per car. Thus, for a tramline of five miles in length, operated with 15 cars from one power station, including the cost of building and machinery, the total amount would be something like £27,000. From other estimates and experience it appears that the cost of overhead construction in the more substantial manner required for British city and suburban street tramcars, may be taken to be about £15,000 per mile of double track, including the car equipment, while that of single-track road railway in country districts, if constructed on the metre or 3ft. 3in. gauge, can be kept within £6,000 per mile of single-track.

As an example of total cost of construction of an overhead line of four miles in length, the following figures may be given, being taken from the actual experience in the case of the Marseilles-St. Louis Electric Tramway:

Permanent way	£14,400
Overhead system	10,000
Buildings and plant	11,200
18 cars complete	14,560
Offices	5,800
Miscellaneous	1,840
Total	£57,800

or about £15 000 per mile of double track.

The conduit system involves a far greater outlay, and if one may judge by the experience of those lines already constructed on this system, from £9,000 to £10,000 per mile of single track is certainly within the mark This figure is based on the experience of actual construction—such as the conduit system in Washington-ton, U.S.A., and Chicago, U S A., and includes all cost of car equipment power station, and track.

The conduit system involves considerable reconstruction of the roadways and streets, possible interference with sewers and gas and water pipes, and needs an amount of subway work the cost of which it is very difficult to estimate for accurately beforehand. When this is done there still remains the difficulty of keeping the conduit free from street dirt and storm water, draining it completely and getting convenient access to it all of which difficulties have to be grappled with under the definite local conditions, no general principles being a sufficient guide There is therefore little room for doubt that the only practical system of electric tramcar traction at the present moment is the overhead system. If this is carried out with all the precautions and knowledge now available, I do not consider that an overhead system is at all objectionable. The light iron posts which carry the trolley wires can be made available as supports for arc or incandescent lamps in the streets in which they exist, and with proper regard to the construction of this overhead work there is no reason to believe that it would in any way interfere with other traffic, or be a cause of complaint by its appearance.

As regards the cost of working, a careful analysis of a large number of electric railway accounts shows that the average working cost per car mile, exclusive only of interest on capital, is approximately 6½d. in America and 5½d. in Europe, and that the ratio of working expenses to receipts in both countries is approximately 60 per cent. In contrast to which the working cost per car mile on horse tramways appears to be on an average 10d. per car mile, and the ratio of expenses to receipts over 80 per cent.

The following figures show the total cost of working in pence per car mile for some electric lines, interest on capital alone excepted, the figures being taken from a paper by Mr. Wilkinson on this subject.

Electric Railways.	Pence.
Liverpool Overhead	4·35
City and South London	5·31
Bessbrook, Newry	3·97
Electric Tramcar Lines.	
Roundhay-road, Leeds	5·55
South Stafford Electric	4·06
Guernsey, Channel Islands	4·02

And in comparison with this, the following table for the cost in pence per car mile and ratio of operating expenses to receipts for horse tramways:

Name of horse tramway.	Ratio of operating expenses to receipts. Per cent.	Total cost in pence per car mile.
All London tramways	82·7	9·8
Birmingham, Midland	81·22	13·22
,, Central	76·79	9·96
Dublin United	73·80	9·77
Dundee	73·75	10·78
Leicester	83·78	9·80
Sheffield	79·85	9·95
Newcastle and Gosforth	90·51	11·25

A large number of other figures might, if necessary, be supplied to show the favourable manner in which overhead electric traction compares with horse-car traction in point of cost of working, and the enormous extent to which electric traction has proceeded in the United States is the indirect proof of this fact.

With regard to accumulator cars, it is not possible up to the present time to give a very good account of this system of working, for although many experiments have been made, the greater weight of the cars, the depreciation of the batteries and cars, and the higher operating expenses caused chiefly by the cost of handling the accumulators, amount to about 9d. or 10d. per car mile, have militated against the progress of accumulator traction; and although the advantages of this system of working may continue to make inventors push forward improvements, I cannot at the present moment advise the adoption of battery tramcars as an undertaking on which a municipal authority might safely embark.

On the other hand, there are systems of operating tramcars by alternating currents which have a favourable aspect. Near Dublin, at the present time, a tramcar line is being equipped by the British Thomson-Houston Company, in which three-phase alternating currents will be used for transmitting the power for long distances, and transformer-motors used to convert the alternating current into a continuous one. This system has the great advantage in that the power-house need not be situated very close to the track, because the electric power may be conveyed at a high pressure by small sized conductors to the proper transformation points.

By whatever system the power is conveyed, it must ultimately be utilised by a system of overhead conductors on the tramline, and as the above figures show, the advantages over horse-car traction in cost of working are undeniable.

As regards the situation of the power-house and its relation to the electric lighting station in Plymouth, there is no doubt but that the interests of economical working will be best served by making one electric station do duty for both plants; the same boilers, and the same superintendence and labour would then be available. Taking it that the electric lighting station is established on the Cattewater site, there would be no difficulty in operating an overhead system for electric traction directly from that site over any of the roads running out eastward from the centre of the town. By the employment of a suitable system any of the tramlines could be operated from the site.

My general suggestion as to electric traction in Plymouth is that a careful consideration should be given to this question of operating one line at first electrically in the eastern part of the town by a well-devised overhead system, and that the system of power transmission should be such as to be capable of being extended to lines running out in other directions, if the results warrant further extension. There can be little doubt but that the establishment of one such electric tramcar line worked from a supply station placed on the Cattewater site would show the advantages of electric traction over horse traction in respect of cost of working. My opinion is, however, that the generating machines necessary for supplying the currents for the electric traction should not be the same as those employed for the electric lighting. There are great objections, owing to the sudden fluctuations in the demand for traction power, to employing the same engines and dynamos for both lighting and traction, though steam for both plants might be supplied in one common battery of boilers.

The figures that I have given above as to the average cost of construction of an overhead system would be a guide to estimate the probable cost of converting, say, three miles of any tramcar line from the horse-car system to the electric traction system. If, however, the electric current is supplied from the same station there would be a certain reduction to be made in these figures, which could only be calculated when the exact position of the line to be operated electrically was known.

The same general advice which I have given with regard to the electric lighting station would apply to the electric traction station—namely, whatever designs were considered should from the very first be drawn with a view of ultimate considerable extension without any alteration of that which is already in place. With the limited data before me, it is not possible to do more than to sum up the electric traction question as regards Plymouth in the following conclusions.

Digitized by Google

1. That there will be no difficulty in supplying the necessary power to operate any tramcar line from the same electric station that supplies current for electric lighting, but separate engines and dynamo machines will have to be employed.

2. That such combined power and lighting station could be placed on the Cattewater site.

3. That it would be desirable to restrict the initial outlay to the conversion of one line of track of some reasonable length from a horse-car to an electric traction system, such line being selected with a view of facilitating as far as possible, not only passenger passenger traffic, but also bringing in and out of Plymouth marketable commodities. The gradients which will be met with will not present any obstacle to a successful system of electric traction.

4. The selected system should be the overhead system. The accumulator-car system is hardly in a condition as yet to enable me to make a recommendation upon it. The conduit system is in my opinion unsuitable, partly on account of the high initial expense, and the very considerable cost of the reconstruction of the roadway, as well as on the ground of the difficulties that would probably be met with in securing the proper drainage of the conduit, and keeping it free from accumulation of street rubbish.

5. I do not feel justified in making any general recommendation as to the working of all the Plymouth tramlines by electricity at once, but I consider that on one of the tramlines having the heaviest traffic, and preferably in the eastern part of the town, the adoption of an electric service by the overhead system would be of unquestionable advantage.

6 There are two methods by which the distribution of power electrically for traction purposes for the whole of the Plymouth tramways could be carried out from a power station situated on the Cattewater site. One of these is the system in process of adoption near Dublin, in which alternating currents are transmitted to transformer centres and then transformed into 500-volt continuous currents for use on the overhead tramline. The other system involves the use of stationary secondary batteries in connection with a similar transformation, and is, I believe, being adopted in the Isle of Man with very good results.

7. I should prefer to reserve an opinion as to the precise details of the system to be adopted, as well as a particular estimate of cost, until the general question has been settled which of the Corporation tramways it is advisable should be first operated electrically. It is impossible to estimate the details of capital outlay, revenue, and working costs until the nature and position of the line, the car service, and full particulars of the traffic are known.

COMPANIES' MEETINGS AND REPORTS.

FROGGATT'S ELECTRIC LIGHTING COMPANY, LIMITED.

An extraordinary general meeting of this Company was held on Monday last at Winchester House, E.C., to consider the following resolution: "That, on the suggestion of the directors and in the opinion of the shareholders, it is desirable that a committee of the shareholders be appointed to confer with the directors on the following subjects: (*a*) the conduct of the business in the past and the causes of a dividend not having been earned; (*b*) the conduct of the business in the future and the steps to be taken to promote the business success of the Company; and that such committee be empowered, if in its discretion it thinks fit, to make a report to the shareholders." Mr. A. de Murrieta, chairman of the Company, presided.

The Chairman, in moving the resolution, said that it was done in accordance with what was indicated by the Board at the last general meeting. They had not come with a prepared list of names for the committee, as they wished the appointments to be made wholly on the initiative of the shareholders.

Mr. H. Keeble wanted to know why they were to appoint a committee. No grounds for it had been given.

Mr. Wildey thought that on that point the report presented at the last meeting spoke for itself. They had made a profit of only £239 in 12 months, and of that he himself could account for £50 or £100. They saw the Company's lights in omnibuses, and they heard of contracts, and the shareholders naturally wanted to know where the money had gone to. Had they been illuminating those omnibuses for other persons' benefit or their own? He seconded the resolution.

Mr. H. Keeble thought the appointment of the committee would be useless after the report of the directors had been accepted. It was practically as though the directors were to say, "We have managed the Company up to the present time; now we are incompetent to carry it on. Tell us what to do." The proposal was either a simple waste of time, or an attempt to wreck the Company. He proposed as an amendment that the committee should report to the shareholders.

Mr. Hayward seconded this, with the addition that the report should be presented within 28 days.

The **Chairman** said the Board would oppose the limit of 28 days, otherwise they did not object. The purpose of leaving it in the discretion of the committee to report was because they might have to discuss certain matters which it would not be for the interests of the Company to make public.

Upon a show of hands, the amendment was lost and the original resolution carried.

Mr. H. Keeble demanded a poll, and three shareholders being necessary for that purpose, Messrs Hayward, Baxter, Lyons, and Partridge joined in the demand.

The **Chairman** appointed the following day for the poll, and the meeting was adjourned to Thursday at four o'clock.

At the adjourned meeting on Thursday, Mr. A. de Murrieta presiding, the result of the poll was declared as follows:

For the resolution	19,224
Against	11,578
Majority	7,646

Mr. Stanhope, Mr. C. Hunter, and Mr. Hayward were appointed the committee.

EASTERN EXTENSION, AUSTRALASIA, AND CHINA TELEGRAPH COMPANY, LIMITED.

The directors, in their report for the half year ended June 30 last, state that the gross receipts, including Government subsidies, have amounted during that period to £264,138, against £247,681 for the corresponding half-year of 1894 The working expenses, including £29,323 for cost of repairs to cables and expenses of ships, absorb £95,254, against £80,295 for the corresponding period of 1894, leaving a balance of £168,883 From this is deducted £3,984 for income tax, £31,895 for interest on debentures, debenture stock, and contributions to sinking fund, leaving £133,004 as the net profit for the half-year. Two quarterly interim dividends of 1¼ per cent. each, amounting to £62 500, have been paid for the half-year under review, leaving £70 504 to be carried forward. The working of the Australasian tariff arrangement for the fourth year of guarantee, ended April 30 last, resulted in the guaranteed figure being slightly exceeded, owing to the exceptionally heavy gold-mining traffic that was exchanged with Australasia during the latter part of the year. The maintenance ships have, as usual, been kept employed during the half-year under review on the various sections of the Company's cables; but owing to the cables being duplicated, the traffic has in no instance been interrupted.

MONTE VIDEO TELEPHONE COMPANY.

The directors, in their report for the year ended July 31 last, state that the accounts show a net profit for that period of £7,232. This amount added to the balance of £577 brought forward from last year leaves a sum of £7,810 available, after providing for all the working expenses in Monte Video and London and for loss in exchange, and after writing off amounts for bad debts and depreciation of office furniture. The working expenses in Monte Video have been somewhat heavier during the current year, the increase being attributable to a succession of severe storms during the early part of this year, when much damage was done to the plant. At the cost of revenue, however, the property has been maintained in good working order. After placing £1,000 to reserve account and £500 to the depreciation fund, the directors recommend the payment of a dividend of 4 per cent. on the preference share capital, leaving the sum of £710 to be carried forward to next year.

CONTRACTS FOR ELECTRICAL SUPPLIES.

CONTRACTS OPEN.

Ceva (Italy).—The Municipality of Ceva, Mondovi-Cuneo, invite offers for lighting the town by electricity. Address, Il Municipio di Ceva.

Guernsey.—The Guernsey Railway Company, Limited, invite tenders for two electric motor bogie cars, with top transverse seats and reversible backs, to seat 80 persons and suitable for the overhead wire system. Particulars can be obtained on application to the secretary, Guernsey.
